PLANTS to RAYMUND OF TRIPOLI

PLANTS AND PLANT SCIENCE. In the most generally used sense a plant is a member of the vegetable class of living things, plants and animals being the two classes into which living things (organisms) are roughly divided. With the higher forms the difference is very definite and leaps to the eye. In the case of lower forms of life the distinction is often very difficult, and indeed it is an artificial one, since plants and animals probably had common ancestors in evolution. The early use of the word "plant" was for a twig, shoot, cutting or sapling, which is the meaning of the Latin *planta*. Other meanings of the word are derived from the verb "to plant," *i e*, to fix in position or place. It is thus used of the fixtures, machinery or apparatus necessary for carrying on an industry or business, in colloquial or slang use it is applied to a swindle, a carefully arranged plot or trap laid to deceive. (*Cf* also PLANTATION)

In the following sections the botanical sense of the term is followed. An outline of the classification of plants is given under BOTANY and the chief groups, Algae, Fungi, Gymnosperms, etc., are dealt with in separate articles

brown, etc.) and the FUNGI (including the Bacteria), which are colourless parasitic or saprophytic plants derived by reduction from algalike ancestors or, more probably, descended from certain colourless flagellates. The lichens are a peculiar group of composite plants, consisting of an alga and a fungus living in association (*See* ALGAE, FUNGI; LICHENS)

The BRYOPHYTA (*q v*), which include the Hepaticae or liverworts and the Musci or true mosses, are distinguished from the Thallophyta by the fact that the sex organs are multicellular, the female reproductive organs are structures known as archegonia, and the male organs are called antheridia.

The group PTERIDOPHYTA (*q v*), or fernlike plants, includes all the cryptogams higher than the Bryophyta. The plants show a marked differentiation into roots, stems and leaves (or fronds), some of the latter being of very great size and much divided. Furthermore, they show well-marked vascular strands, and their female reproductive organs are archegonia. This large group includes the Filicineae (true ferns), the Equisetineae (horsetails, etc.); and the Lycopodiineae (club mosses, etc.).

PLANTS AND PLANT SCIENCE

An outline of Egger's classification is given below, the orders (series) being printed in black-faced type and the families in italics. For the 11 orders of monocotyledons a synopsis of the chief characters is given. A selection of the more important families is made in the case of the orders which include a large number of families.

MONOCOTYLEDONS

Order 1 **Pandaniales**—(Marsh herbs or shrubs or trees with large narrow leaves and compound heads or spikes of flowers. Seeds rich in endosperm) *Typhaceae*, *Pandaneaceae*, *Sporangaceae*.

Order 2 **Najadales**—(Water or marsh plants with cydric or hemicydric flowers, often enclosed in a spathe. Embryo large with little or no endosperm) *Potamogetonaceae*, *Najadaceae*, *Athaceae*, *Bulmaceae*.

Order 3 **Triuridiales**—(Saprophytes with scaly leaves and small long-stalked flowers) *Triuridaceae*.

Order 4 **Graminales**—(Usually annual or perennial herbs with naked flowers covered by bracts. Ovary unilocular with one ovule) *Gramineae*, *Cyperaceae*.

Order 5 **Palmales**—(Plants, usually trees, leaves of large size often fanlike or featherlike, male and female flowers usually in spikes enclosed in a spathe, ovary superior and fruit a berry or drupe with rich endosperm) *Palmaceae*.

Order 6 **Cyclanthales**—(Often palmlike or climberlike or large herbs with male and female flowers arranged alternately over the surface of a spike) *Cyclanthaceae*.

Order 7 **Arales**—(Herbaceous or woody plants, sometimes climbing, flowers on a simple spike [spadix] more or less enclosed in a bract) *Araceae*, *Lemnaceae*.

Order 8 **Xridales**—(Herbaceous or sometimes grasslike in habit, flowers cyclic, hermaphrodite or unisexual, androecium often reduced, ovary usually orthotropous, endosperm mealy) *Bromeliaceae*, *Commelinaceae*, *Pontederiaceae*.

Order 9 **Liliates**—(Usually herbs, often with bulb, corm or rhizome, perianth petaloid or glume-like, ovary trilocular superior or inferior; fruit a capsule or berry; ovule anatropous; endosperm fleshy or oily) *Juncaceae*, *Liliaceae*, *Amaryllidaceae*, *Dioscoreaceae*, *Iridaceae*.

Order 10 **Scitamineales**—(Tropical, large, perennial herbs, often with sheathing leaves; flowers hermaphrodite and irregular, androecium often reduced; ovary inferior, usually trilocular, fruit a berry or capsule with numerous seeds with much perisperm, little or no endosperm) *Musaceae*, *Zingiberaceae*, *Cannaceae*.

Order 11 **Orchidales**—(Flowers of a pentacyclic trimerous type but often with great reduction in the stamens; ovary inferior; fruit a capsule with numerous minute seeds containing a very small undifferentiated embryo) *Orchidaceae*, *Burmanniaceae*.

DICOTYLEDONS

APCHICHLAMYDEAE—(Flowers often without a perianth, usually polypetalous, wind pollination in the lower orders, insect pollination in the higher orders)

Order 1 **Casuarinales**—*Casuarinaceae*.

Order 2 **Piperales**—*Piperaceae*, *Chloranthaceae*.

Order 3 **Salicales**—*Salicaceae*.

Order 4 **Garryales**—*Garryaceae*.

Order 5 **Myricales**—*Myricaceae*.

Order 6 **Balanopsidales**—*Balanopsideae*.

Order 7 **Leitneriales**—*Leitneriaceae*.

Order 8 **Juglandales**—*Juglandaceae*.

Order 9 **Batiidales**—*Batiidaceae*.

Order 10 **Julianiales**—*Julianiaceae*.

Order 11 **Fagales**—*Betulaceae*, *Fagaceae*.

Order 12 **Urticales**—*Ulmaceae*, *Moraceae*, *Urticaceae*.

Order 13 **Proteales**—*Proteaceae*.

Order 14 **Santalales**—*Santalaceae*, *Loranthaceae*, *Balanophoraceae*.

Order 15 **Aristolochiales**—*Aristolochaceae*, *Rafflesiaceae*, *Hydnoraceae*.

Order 16 **Polygonales**—*Polygonaceae*.

Order 17 **Chenopodiales**—*Chenopodiaceae*, *Amaranthaceae*, *Phytolaccaceae*, *Caryophyllaceae*.

Order 18 **Ranales**—*Nymphaeaceae*, *Ranunculaceae*, *Berberidaceae*, *Magnoliaceae*, *Lauraceae*.

Order 19 **Rhoeadales**—*Papaveraceae*, *Cruciferae*, *Rosaceae*.

Order 20 **Sarraceniales**—*Sarracenaceae*, *Nepentaceae*, *Droseraceae*.

Order 21 **Rosales**—*Podostemaceae*, *Crassulaceae*, *Saxifragaceae*, *Hamamelidaceae*, *Platanaceae*, *Rosaceae*, *Leguminosae*.

Order 22 **Pandanales**—*Pandaneaceae*.

Order 23 **Geraniales**—*Geraniaceae*, *Oxalidaceae*, *Tropaeolaceae*, *Linaceae*, *Rutaceae*, *Melastaceae*, *Polygalaceae*, *Euphorbiaceae*, *Callitrichaceae*.

Order 24 **Sapindales**—*Buxaceae*, *Empetraceae*, *Aceraceae*, *Sapindaceae*, *Balsaminaceae*.

Order 25 **Rhamnales**—*Rhamnaceae*, *Vitaceae*.

Order 26 **Malvales**—*Tiliaceae*, *Malvaceae*, *Sterculiaceae*.

Order 27 **Parietales**—*Dilleniaceae*, *Ochnaceae*, *Elatnaceae*, *Cistaceae*, *Buxaceae*, *Violaceae*, *Passifloraceae*, *Begoniaceae*.

Order 28 **Opuntiales**—*Cactaceae*.

Order 29 **Myrtales**—*Thymelaeaceae*, *Elaeagnaceae*, *Lythraceae*, *Rhizophoraceae*, *Myrtaceae*, *Onagraceae*, *Hippuridaceae*.

Order 30 **Umbellales**—*Araliaceae*, *Umbelliferae*, *Cornaceae*, *Metachlamydeae* (or *Sympetalae*)—(Flowers usually sympetalous, i.e., with the parts of the corolla more or less united, often resulting in a tubular flower)

Order 1 **Ericales**—*Pyrolaceae*, *Ericaceae*, *Epacridaceae*.

Order 2 **Primulales**—*Myrsinaceae*, *Primulaceae*.

Order 3 **Plumbaginiales**—*Plumbaginaceae*.

Order 4 **Ebenales**—*Sapotaceae*, *Ebenaceae*.

Order 5 **Cortortaes**—*Oleaceae*, *Gentianaceae*, *Apocynaceae*, *Asclepiadaceae*.

Order 6 **Tubiflorae**—*Convolvulaceae*, *Polemoniaceae*, *Borraginaceae*, *Verbenaceae*, *Labiatae*, *Solanaceae*, *Scrophulariaceae*, *Ignoniaceae*, *Orobanchaceae*, *Acanthaceae*.

Order 7 **Plantaginiales**—*Plantaginaceae*.

Order 8 **Rubiales**—*Rubiaceae*, *Caprifoliaceae*, *Adoxaceae*, *Valerianaceae*, *Dipsacaceae*.

Order 9 **Cucurbitales**—*Cucurbitaceae*.

Order 10 **Campanulales**—*Campanulaceae*, *Compositae*.

The classification described above is the time-honoured system, but one which modern research has found to be unnatural at many points. Recent investigations in the fields of palaeobotany, algology, mycology, and comparative morphology have led to the development of a new classification of the plant kingdom which seems to be more natural than the older scheme. An outline of this modern classification is given below, together with the older group names which are placed near the right-hand margin for convenience of comparison (from O. Tippo, "A Modern Classification of the Plant Kingdom," *Chromica Botanica*, vol. vii [Sept. 1942]).

KINGDOM PLANTAE

Sub-kingdom Thallophyta	
Phylum Euglenophyta	
<i>Euglenae</i> , etc.	
Phylum Cyanophyta—blue-green algae	
<i>Cyanobacteria</i> , etc.	
Phylum Chlorophyta—green algae	
<i>Ulothrix</i> , <i>Cladophora</i> , etc.	
Phylum Chrysophyta—yellow-green algae, golden-brown algae, and diatoms	
<i>Triboana</i> , <i>Dinobryon</i> , <i>Nitzschia</i> , etc.	"Algae"
Phylum Rhodophyta—red algae	
<i>Polysiphonia</i> , <i>Gracilaria</i> , etc.	
Phylum Pyrrophyta—cryptomonads and dinoflagellates	
<i>Peridinium</i> , etc.	
Phylum Schizomycophyta—bacteria	
<i>Bacillus</i> , etc.	
Phylum Myxomycophyta—slime moulds	
<i>Physalis</i> , <i>Slime</i> , etc.	
Phylum Eumycophyta—true fungi	
Class Phycomycetes—algae fungi	
Class Ascomycetes—asc fungi	
Class Basidiomycetes—club fungi	
Class Imperfecti—imperfect fungi	
Sub-kingdom Embryophyta	
Phylum Bryophyta (Archaeata)—mosses and liverworts	
Class Hepaticae—liverworts	
Class Musci—mosses	"Bryophytes"

Phylum Tracheophyta (Tracheata)
 Sub-phylum Palmaria
 Class Palmariales
 Order Palmariales
 Rhodospirillum rubrum, etc.
 Order Rhodospirillales
 Rhodospirillum rubrum, etc.
 Sub-phylum Lycopodiophyta
 Class Lycopodiophyta
 Order Lycopodiophyta—club mosses
 Lycopodium and Phyllocladus
 Order Selaginellales—small club mosses
 Selaginella
 Order Lepidodendroidales—giant club mosses
 Lepidodendron, etc.
 Order Psaroniales
 Psaronius
 Order Isoetes—quillworts
 Isoetes
 Sub-phylum Sphenophyta
 Class Equisetines
 Order Equisetales
 Equisetum, etc.
 Sub-phylum Pteridophyta
 Class Filicinae—ferns
 Order Equisetales
 Order Ophioglossales—adder's tongue ferns
 Ophioglossum, Botrychium, etc.
 Order Marattiaceae—marattiaceous ferns
 Marattia
 Order Filicales—"true" ferns
 Polypodium, Platanus, Asplenium, etc.
 Class Gymnosperms
 Sub-class Cycadophytae
 Order Cycadophytae (Pteridospermae)—
 "seed ferns"
 Cycas, etc.
 Order Bennettitales
 Bennetia, Williamsonia, etc.
 Order Coniferales
 Conifer, etc.
 Sub-class Coniferophytae
 Order Coniferales
 Conifer, etc.
 Order Gnetales
 Gnetum, Ephedra and Welwitschia
 Class Angiosperms
 Sub-class Dicotyledonae
 Order Magnoliaceae ("Archichlamydeae"
 (Ranunculales), etc., ("Choripetalae")
 Order Ericales ("Metachlamydeae"
 etc., etc.
 Sub-class Monocotyledonae

"Pteridophytes"

"Spermatophytes"

BIBLIOGRAPHY—One of the best surveys of the classification of plants is given by A. Engler and L. Diels, *Syllabus der Pflanzenfamilien* (Berlin, 1936); see also R. Wettstein, *Handbuch der Systematischen Botanik* (Leipzig, 1935); J. Hutchinson, *The Families of Flowering Plants* (vol. 1, 1926, vol. 2, 1934, London); A. B. Rendle, *The Classification of Flowering Plants* (vol. 1, 1930, vol. 2, 1938, Cambridge); and J. C. Willis, *A Dictionary of the Flowering Plants and Ferns* (Cambridge, 1931), which not only includes an outline of classification but gives in alphabetical order a brief account of the families and genera of all gymnosperms and angiosperms and also of the ferns. The fullest account of the classification of the plant kingdom is given by A. Engler, *Die natürlichen Pflanzenfamilien* (Berlin, 1887-1915), a work in over 20 volumes, of which a new edition (1925-) is now in progress. Good introductions to the systematic botany of flowering plants are D. B. Swingle, *A Textbook of Systematic Botany* (1934); A. M. Johnson, *Taxonomy of the Flowering Plants* (1931); and R. J. Pool, *Flowers and Flowering Plants* (1941); these books explain the basis of taxonomy (classification) and the terms used, and give a review of some of the important works in systematic botany. Newer systems of classification are treated in A. J. Eames, *Morphology of Vascular Plants* (1936); in G. M. Smith, *Cryptogamic Botany*, vol. 1 (1938); and in O. Tippo, "A Modern Classification of the Plant Kingdom," *Chronica Botanica*, vol. VII, p. 203 (1942) (O. T.).

MORPHOLOGY OF PLANTS

Plant morphology is concerned with the form and structure of plants and of their parts, and with the relation of parts to one another and to the whole. Morphology is thus fundamentally descriptive. A morphological study may be merely the determination of the facts of the history of an organism through all stages of development and reproduction; that is, it may be a purely descriptive life-history study. As commonly understood today, however, morphology has a broader basis: its object is to trace the underlying similarities in form between various plant groups, it is comparative in its nature, and its comparisons are considered in the light of evolutionary modification and development. Morphology thus conceived aids in the establishment of

a natural classification of plants and in the reconstruction of their evolutionary history (phylogeny).

The methods used in morphological studies are: (1) comparison of adult forms of living plants, (2) comparison of living plants with the ancient extinct forms as the latter are determined in the studies of fossils (palaeobotany), (3) observations on development of the individual (ontogeny). Morphology is generally subdivided into *external morphology* which deals with the external form, and *anatomy*—the study of the external and internal structure of plants. *Cytology*, study of the cell, arose as a subdivision of morphology concerned with internal structure, but it has become an independent branch of biological science. A morphological study may assume a somewhat specialized aspect. Thus it may deal with the early development of an individual (embryology); with the causes that determine form and structure (morphogenesis), or with plant parts considered as organs carrying out certain distinct functions (organography).

Alteration of Generations.—The phenomenon of alteration of generations is so prominent and important a feature of the morphology of plants that for many years it has been one of the main objects of morphological studies. The term alteration of generations is used to designate the occurrence of two distinct phases in the life history of the plant, each of which produces the other. One is the sexual phase, the *gametophyte*, that bears male and female organs (gametangia) and gametes (sperms and eggs) and in which fertilization (syngamy) is effected. The fertilized egg (zygote) develops into a non-sexual phase, the *sporophyte*, which produces a large number of single-celled spores. The latter develop directly into new gametophytes. The two phases of the life cycle are commonly referred to as "generations," though actually they are two phases of one generation, if the latter concept is used in the same sense as in zoology.

At fertilization the number of chromosomes is doubled through the union of two gametes. At some other point of the life cycle this number is again halved through *reduction divisions* (meiosis). The phase of the life cycle in which all cells have a double complement of chromosomes (diploid) and which begins with the fertilization and ends with the reduction divisions is the sporophyte. The phase characterized by a single complement of chromosomes (haploid), from reduction division to fertilization, is the gametophyte. The character and relative extent of these two phases differ considerably in different groups and show great variability in the lower plants. In many of the thallophytes (Algae and Fungi) almost the entire life cycle is gametophyte, since the first divisions of the zygote are meiotic, in others it is almost all sporophyte. Still others show varying

AFTER G. M. SMITH, "CRYPTOGAMIC BOTANY," MCGRAW-HILL BOOK CO.

FIG 1.—DIAGRAM SHOWING THE VARIOUS TYPES OF LIFE CYCLE AMONG THE CHLOROPHYCEAE (GREEN ALGAE). A, CHLAMYDOMONAD, B, HAPLONTIC, C, DIPLONTIC, D, DIPLOHAPLONTIC

degrees of relative development of these two phases, and often both are vegetative plants entirely similar in everything except the method of reproduction.

The diagrams give examples of different types of life cycles. The simplest possible life cycle (chlamydomonad) occurs in the unicellular Chlorophyceae (green algae). It consists of an alternation of a one-celled haploid phase with a one-celled diploid phase (fig. 1, A). In the somewhat higher Chlorophyceae vegetative cell divisions occur in one or the other or in both phases. In the *haplont* type a multicellular haploid phase alternates with a unicellular diploid one (fig. 1, B). In the *diploonts* the life cycle consists of an alternation of a diploid coenocyte (the morphological equivalent of a multicellular diploid generation) with a unicellular haploid phase (fig. 1, C). Certain Chlorophyceae are diplohaplonts and have an alternation of a many-celled haploid generation with a many-celled diploid generation (fig. 1, D).

The gametophyte is the dominant phase or "the plant" of the mosses (Bryophyta), whereas the sporophyte is merely a spore-bearing structure that develops from the zygote and remains attached to the gametophyte (fig. 2). In contrast, the vascular plants (Tracheophyta) have a large and conspicuous sporophyte with roots, stems and leaves and predominates in the life history. The fern sporophyte bears the spores on the backs of its leaves. Each spore may develop into a small but independent generation, the gametophyte or prothallus, on which the sex organs are borne (fig. 3). In the gymnosperms and angiosperms the gametophyte generation is extremely reduced. The spore (megaspore) producing the female gametophyte (megagametophyte) remains attached to the sporophyte after germination. Other spores (microspores) germinate to form the male gametophytes (pollen grains), which are liberated and carried to or near the ovule containing the

female gametophyte. One of the two male gametes (sperms) produced by the male gametophyte fertilizes the egg. The zygote grows at once into the embryo (fig. 4).

Two theories have long existed concerning the nature and origin of the sporophyte of vascular plants, the *antithetic theory* and the *homologous theory*. The first assumes that the two phases are essentially distinct, that the sporophyte is a new phase introduced into the life cycle of vascular plants in relation to life in air. It is supposed to have evolved from the zygote of an ancestral algal form through a stage in which it was merely a spore-bearing structure wholly dependent upon the gametophyte.

According to the homologous theory (which is supported by modern morphological and palaeobotanical studies), the sporophyte and gametophyte are fundamentally alike in nature; they are correlative phases in the life cycle of plants that have arisen by modification of an original single sexual phase. In recent interpretations the homologous theory places the differentiation of the gametophyte and sporophyte in ancient algal stocks and assumes the origin of land-living independent sporophytes directly from independent aquatic sporophytes.

Plant Body.—In the simplest plants the body consists of a single cell within which all life activities are carried on. According to the evolutionary concept, the simple cells united into colonies forming at first a loose, later a more intimate, union, until a *multicellular plant* arose. With the advent of "division of labour" between the different parts of the multicellular body, a morphologic differentiation of these subdivisions occurred, so that a very complex plant body now appears in the higher plant groups. While in the lowest plants any part may perform all functions, in the highest the various functions have organs devoted to their performance, and in these the cells are grouped

FIG. 3.—DIAGRAM SHOWING THE LIFE CYCLE OF A TRUE FERN (POLYPODIUM)

in definite and very specialized tissues. The lower plants (Thallophyta) show various degrees of complexity of form and structure. Certain groups of red and brown algae somewhat resemble the higher plants in the formation and arrangement of the members of their bodies. The progressive differentiation of the thallus of the liverworts and mosses (Bryophyta) presents an even closer parallel to the organization of the higher plants. Some of these have stemlike and leaflike body parts resembling organs of the most highly organized plants. True roots, stems and leaves, however, do not occur in either thallophytes or bryophytes. These are characteristic organs of the vascular plants (Tracheophyta). According to a modern concept, these organs evolved with the invasion of the dry land by plants that formerly inhabited only the sea.

The nature of the plant body and its parts in vascular plants has long been a basic morphological problem. As was shown in the preceding section, it is the body of the sporophyte that is so complex in the higher plants. The gametophyte is extremely simple. In early days of morphological study the sporophyte body was looked upon as constituted of organs that were of different fundamental nature. The number of these organs was at first large, for example, stem, root, leaf, ovule, sporangium, sporangio-phore, emergence, hair. With the development of the concept of homologies, the interrelation of parts of a plant body began to be recognized. Comparative and developmental studies suggested that differently appearing parts may bear the same relation to the whole plant body, that, in other words, they may be *homologous*. For example, the flower appeared homologous with the shoot, the floral members with leaves. In contrast, if parts differ in their relation to the whole, but are similar in function and structure, they are *analogous*. Thus the flattened green stem of many plants of dry habitats are analogous with leaves. With increase in comprehension of the relationship between parts the units of structure became reduced to three: stem, leaf and root.

The recent discoveries of early land plants and studies in development have indicated that even these three categories of parts are not absolute, but are results of evolutionary development and cannot be clearly separated morphologically. The general nature of the plant body seems to be that of an axis. Under this interpretation there are no fundamental parts. Roots and leaves, as elaborated organs, are secondary structures that differentiated on an originally primitive axis. The leaf may have arisen in two ways: (1) as a lateral emergence of the axis, and (2) as a branch system that became flattened and expanded, with a webbing of tissue uniting the branches into one. The view upon the relation of the angiospermous flower to the other plant parts is also in a state of flux. The concept of the flower as a modified shoot, and particularly that of the homology between the leaf and the carpel, is being contested. The complex problem of the nature of the plant organs is still awaiting its final clarification. A judicious use of data on ontogeny, vascular anatomy, palaeobotany and comparative morphology should eventually bring about such clarification.

ANATOMY OF PLANTS

Anatomy deals with structure, gross and minute, external and internal. A special field of anatomy is *histology*, which is concerned with the minute structure of organisms. If an anatomical study deals with the structure of cells, particularly with the protoplast, it enters the field of *cytology*. Thus anatomy merges

FIG. 4.—DIAGRAM SHOWING THE LIFE CYCLE OF WHEAT (TRITICUM)

with cytology and only an arbitrary limit may be set up between the two.

The Cell.—An account of the anatomy of plants naturally begins with the cell, which is the proximate unit of organic structure. The cell is essentially an individualized mass of protoplasm, of small dimensions and containing many specialized structures, chief among which is the *nucleus*. Other protoplasmic bodies, known as plastids, and inanimate matter, are present. The different living bodies and nonliving inclusions are dispersed within the more or less fluid living substance called *cytoplasm*. Among the nonliving inclusions are starch grains, crystals of various shapes and compositions, oil globules, tannins and food masses of different sorts. Much of the inanimate matter occurs in a watery solution forming the cell sap. All cells that are permanent tissue elements of the plant body possess a more or less rigid limiting membrane or *cell wall*, consisting primarily of cellulose or some allied substance excreted by the living cell body. The presence of plastids in the protoplasm and the existence of the cell wall are the two main characteristics that differentiate plant cells from those of animals.

The walls of adjacent cells are cemented together so that the cells are united into more or less coherent masses or tissues. Upon the characters of constitution, thickness and sculpture of the cell walls, the qualities of a plant tissue largely depend. The life of all the cells in a plant body may be prolonged, or a number of the cells may die and their protoplasm be removed. Thus a tissue may consist of living cells combined with an inanimate framework of cell walls, enclosing in their cavities solely liquids and gases. In such cases the characters of the adult tissue largely depend on the proportion and distribution, the size, form and contents of the living and dead units, and on the nature of their walls.

In all but the simplest forms the plant body is composed of cells associated in more or less definite ways. In the higher or more complicated plants the cells differ greatly among themselves so that the adult body is composed of definite systems of units, the *tissue systems*. Each system has its own characteristic structure, depending partly on the characters of the component cells and partly on the method of association.

The structure and development of the plant cell with regard to

the protoplasm and the nucleus are considered in detail in the article CYTOLOGY.

Plastids.—The plastids are portions of the protoplasm that have become specialized for the performance of certain functions. They are readily distinguished in the adult cell by their size and definite form, and they are often conspicuously coloured. Leucoplasts are colourless and occur in the cells of the deeper lying tissues where light cannot penetrate—if exposed to light they often become green. They are frequently concerned with the formation of starch grains. Chromoplasts are colour-carrying bodies giving red and yellow colours to the petals of flowers, ripe fruits, etc., they contain yellow and red pigments such as xanthophyll and carotin. The most important of all the plastids, however, are the green chloroplasts. These contain chlorophyll and are of universal occurrence throughout the plant kingdom with the exception of the important groups of Fungi and Bacteria. By means of this pigment the plastids are enabled in the presence of light to form carbohydrates from water and carbon dioxide. The chloroplasts are extremely variable in shape, particularly in the Algae. In the higher plants the chloroplast is discoid and, according to the prevalent view, consists of a mass of somewhat dense colourless cytoplasm, the *stroma*, and of granules containing chlorophyll. Chloroplasts frequently include starch grains.

The differentiated plastids seen in mature tissues may be traced back to plastid primordia, or *proplastids*, in the youngest tissues (*meristems*) or embryo. The proplastids appear in the cytoplasm of the young cells as minute bodies grading off to the limit of visibility. At all stages of development from proplastids, and at maturity, the plastids may divide by simple constriction. These divisions are sufficiently numerous to account for the large numbers of plastids in mature cells. It has not been disproved, however, that plastids arise also anew (*de novo*) in the cytoplasm. The problem of individuality of the plastid is mainly one of determining whether they are continuous or not through the critical stages in the life cycle, the gametes and spores. They have been shown to be present in the gametes and spores of some plants and are, in these instances, apparently passed on from one generation to another.

Mitochondrion.—In addition to the plastids there are other bodies in the cytoplasm which are very minute and appear as tiny granules, rods or threads and whose nature and function are not well understood. They are called *chondriosomes* or *mitochondria*. According to one opinion, mitochondria are the bodies from which plastids develop, according to another, the proplastids and mitochondria are distinct structures. Mitochondria are also thought to be concerned with respiration or to be merely food substances.

The Cell Sap.—All living cells in plants contain variable amounts of nonliving materials that are collectively designated as *inclusions* or *ergastic substances*. They include storage products, waste material, or by-products of protoplasmic activity. One of the most common examples of ergastic substances is the cell sap, which occurs, in mature cells, within the central cavity of the cell, or the *vacuole*. On all sides the vacuole is surrounded by cytoplasm and does not come in contact with cell walls. One or more vacuoles may be present in a cell, their number and shape varying from time to time in the same cell. The vacuolar system of a cell or other protoplasmic mass, whether this system consists of one or more vacuoles, is called the *vacuome*. The cell sap is water in which are dissolved substances of various kinds, some being food materials, others products of the metabolism of the protoplasm. Its composition is constantly changing, but among the substances of constant occurrence are inorganic salts, carbohydrates such as the sugars, and soluble nitrogenous compounds.

Vacuoles appear to be universally present in living plant cells. In the youngest, or meristematic cells, which by division form the tissues and organs of the plant body, the vacuoles are rather numerous, small spherical, or drawn out into other shapes by the streaming cytoplasm in which they are dispersed. As the meristematic cells multiply, the vacuoles are distributed, with or without

division, to the daughter cells. During the enlargement and maturation of the cell the vacuoles increase in size and eventually coalesce to form one large central vacuole in the cytoplasm, which thus becomes restricted to a comparatively thin layer closely applied to the cell wall.

The Cell Wall.—The cell wall in meristematic cells is thin and extremely delicate but, with the completion of the growth in size of the cell, it is increased in thickness and may in certain cases undergo considerable modification. It is commonly regarded as a secretion of the protoplasm and is, in living cells, in intimate relation with the protoplasm which may interpenetrate the particles of its substance. This close relation can be readily appreciated when the process by which the wall is first laid down is considered. From the beginning of the plant's existence as a single cell, all new cell formation consists in the division of a pre-existing cell into two halves by the formation of a dividing wall. In this process the cytoplasmic spindle, which functioned in the preceding nuclear division (*see* CYTOLOGY), plays an important part. The new wall begins with the appearance of a *cell plate* dividing the spindle in two halves (Pl. I, fig. 3). If the spindle does not reach to the side walls of the dividing cell, new fibres arise on its periphery and extend the cell plate to the side walls (Pl. I, figs. 4, 5). The cell plate is a fluid layer appearing first as minute droplets that unite to form a continuous layer. Some interpret these small units as swellings of the spindle fibres. The fluid cell plate apparently soon solidifies and becomes part of the wall. The two daughter protoplasts that resulted from the division of the original cell secrete additional wall substances. These are deposited among the existing particles (intussusception) and also over the inner surface of the new wall (apposition). Thus the wall becomes thicker. The amount of wall material deposited varies in different kinds of cells. One extreme is cells with walls that are little thicker than those of the meristematic cells from which they arose, the other, cells whose lumina are almost filled with wall material.

Commonly the wall does not appear homogeneous, but shows layering. The layers may differ in origin, appearance, when viewed in polarized light, and chemical and physical structure. Three main categories of wall layers exist. (1) The *intercellular substance*, which is composed of pectic substances and is isotropic (*i.e.*, dark or non-refracting when viewed under polarized light). This substance acts as a cementing material binding the walls of adjacent cells together. Some regard it as being derived from the cell plate formed during cell division. (2) The *primary wall*, which consists largely of cellulose and pectic substances and is anisotropic (*i.e.*, bright or refracting when viewed under polarized light). It occurs next to the intercellular substance. Many thin-walled tissues contain only primary walls (Pl. I, fig. 11). These walls, however, may also be comparatively thick. They are formed while the cell is still enlarging during differentiation from a meristematic cell. (3) The *secondary wall*, which

FIG. 5.—CELL WALL TYPES IN PRIMARY XYLEM SHOWN IN A LONGITUDINAL SECTION OF VASCULAR BUNDLE IN A STEM

AFTER E. W. SIMMONS, "BOTANY PRINCIPLES AND PROBLEMS," MCGRAW HILL BOOK CO.

is extremely complex, physically and chemically, and strongly anisotropic (Pl. I, fig. 12). Cellulose is its basic component and it is formed after the cell attains its final size and shape. The secondary wall of plant cells is rarely continuous over the entire surface of the underlying primary wall. It may develop as discrete rings, spirals, bars, or as complex network or mesh, or it may cover most of the primary wall except for small interruptions or cavities which are termed *pits* (fig. 5). All three wall layers may become modified by impregnation with a variety of inorganic and organic substances, notably lignin, which renders the walls firm and hard.

The anisotropy of the primary and secondary walls (Pl. I, fig. 13) indicates that they are crystalline in nature. The crystalline properties are imparted to the wall by cellulose, a carbohydrate with the general formula $(C_6H_{10}O_5)_n$. The units $C_6H_{10}O_5$ (anhydrous glucose residues) are combined into long chains—the cellulose molecules. These chain-molecules tend to occur in aggregations within which the molecules are arranged parallel to one another with characteristic spacings between the chains. The molecules and their aggregations are too small to be seen through a microscope and are studied by their effect upon X-rays and a polarized light. The aggregations of chain-molecules appear to overlap each other and form a coherent system perforated by a continuous system of spaces. Within these spaces substances other than cellulose (e.g., lignin, fatty substances, water) are deposited. As seen through the microscope after special treatments the cellulose wall also appears as a continuous system of microfibrils interpenetrated by a system of micropores. How the sub-microscopic system formed by the aggregations of chain-molecules and the microscopic system of microfibrils are related to each other is not yet clear.

Many conspicuous differences in the optical and mechanical properties of cell walls are correlated with variations in the orientation of the microfibrils. If the latter are oriented parallel to the long axis of the cell, the wall or layer in which they occur does not contract longitudinally in drying. The opposite is true if the walls have transversely oriented microfibrils. Various intermediate conditions occur in walls whose microfibrils are oriented helically in relation to the long axis of the cell. Microfibrils may be differently oriented in the different wall layers of the same cell.

Plasmodesmata.—The living cell in a complex multicellular plant body is a unit, but not an independent one, and its functions are conditioned by, and related to, the activities of the organism as a whole. This must involve a close connection between the living protoplasm of neighbouring cells, and this is effected by delicate connecting strands, the plasmodesmata, which traverse the walls. The connecting strands may be scattered singly throughout a wall or may be aggregated in thinner places of the wall, the pit areas. Plasmodesmata may represent the persistence of the original continuity of the protoplasm of two sister cells, but also are established when growth is completed. These delicate connections seem to occur universally in the higher plants. They play a part in the correlation of the functions of the cells, and they may also provide the means by which stimuli can be conveyed through long tracts of tissue.

Cell Types and Tissues.—As previously stated, the cells have come to differ greatly among themselves since the plants increased in complexity. Plant cells may vary in size, shape, contents and wall structure, and may be highly specialized with relation to the performance of definite functions.

The chief types of plant cells are as follows. **Parenchyma cells** (Pl. I, fig. 21) are commonly more or less isodiametric in form, have thin walls and active protoplasts. A certain degree of variation in characteristics occurs with relation to the functions performed by parenchyma. Thus the parenchyma cells of the photosynthetic tissue of a leaf are rich in chloroplasts and may be considerably elongated or lobed (Pl. II, fig. 12); the parenchyma cell of a potato tuber contains leucoplasts that store starch, the parenchyma cells within the water-conducting tissue (xylem) may have thick secondary walls. The retention at maturity of living protoplasts is one of the most important characteristics of

parenchyma cells. These cells are regarded as the least differentiated, the least specialized, and they make up the entire plant bodies of most of the Thallophyta (Algae and Fungi). **Collenchyma cells** (Pl. I, fig. 21) occur in layers or strands in the subsurface region of many stems, petioles and ribs of leaves where they serve as a supporting tissue. Like the parenchyma, this tissue retains living protoplasts at maturity. The shape of the cell varies from nearly isodiametric to very much elongated (prosenchymatous). The principal characteristic is the thick cellulose wall, the thickening being irregular and massive. The thickenings occur in strips along most walls, or the tangential walls or only in the corners. The walls are very strong but plastic, and do not hinder the elongation of the growing organs in which collenchyma is the chief supporting tissue. **Sclereids** show similar variations in shape as the parenchyma cells but have very thick lignified walls with tubular pits. The protoplasts are usually lacking at maturity. One of the best-known examples of a sclereid is the stone cell that is a common component of the flesh of the pear fruit. The hard shell of the walnut is made up largely of sclereids. **Fibres** are elongated cells, sometimes very much so, with thick pitted secondary walls (Pl. I, fig. 18) which may be of cellulose or lignified cellulose. The protoplasts usually die when the cells mature. Stone cells and fibres are often treated as elements of one type of tissue called sclerenchyma (mechanical or supporting tissue), because both have thick walls, lack protoplasts and serve for support. The two main groups of fibres are those that occur in the wood tissue, the **xylem fibres**, and those located in various parts of the plant outside the xylem, the **bast fibres**. The xylem fibres are usually lignified and are chiefly responsible for the rigidity and hardness of the wood. Some bast fibres are lignified, others have unmodified cellulose walls. The latter kinds of fibres are valued commercially and occur in such well-known fibre plants as flax, hemp and ramie. **Tracheary elements** are water-conducting elements located in the xylem or wood. The vascular plants are called Tracheophyta because they contain tracheary elements. Two principal types of tracheary elements occur in plants: **tracheids** (fig. 6, A) and **vessel elements** (fig. 6, B, C). Both of these are commonly prosenchymatous with oblique or transverse end walls. They have secondary walls of lignified cellulose that are deposited as rings, spiral bands, bars, a network, or as pitted layers upon the thin primary wall. At maturity the protoplasts are lacking. The principal distinction between the two types of tracheary elements is that the tracheid is an imperforate cell with a continuous primary wall, whereas a vessel element has openings or perforations usually located in the end walls of the cell. The vessel elements are combined into longitudinal pipelike units, the **vessels**, in which water passes freely through perforations from element to element. Water moving through tracheids passes from one cell into the other through places where the secondary wall is discontinuous but the primary wall is present. Often these places are very restricted and are then called pits. The water passes through the exposed part of the primary wall of the pit, the **pit-closing membrane**. In the wood of the gymnosperms (firs and their allies) the pits show very elaborate structure. The pit-closing membrane has small but numerous perforations and is reinforced by a primary thickening, the **torus**, in the middle. The secondary wall overhangs the pit cavity as a border (hence bordered pit), leaving a small opening (pit mouth) at the entrance into the pit cavity (fig. 6, D). The pit-closing membrane is flexible and can bulge one way or the other within the cavity formed by two communicating bordered pits of the adjacent cells. The torus may become appressed to the mouth of one or the other pit, obstructing the entry into the pit cavity. Thus, apparently by changes in the position of the closing membranes of bordered pits, some control is exercised over the passage of fluids in the xylem. **Sieve cells** (fig. 6, G) and **sieve-tube elements** (fig. 6, F) are the characteristic components of the tissue concerned with the conduction of the manufactured food (chiefly sugars and protein), the **phloem**. The sieve-tube elements occur in the angiosperms (plants having their seeds enclosed in an ovary), whereas sieve cells are typical of gymnosperms and ferns. The sieve-tube

elements have specially modified walls or portions of walls called *sieve plates* (fig 6, E). The essential feature of a sieve plate is the presence of perforations (sieve-plate pores) in the wall through which the protoplasts of two adjacent or superposed elements are continuous. These connecting strands are comparable with plasmodesmata but tend to be thicker than ordinary plasmodesmata. In the sieve plate a special kind of carbohydrate, *callose*, surrounds each strand (Pl I, fig 17). In other words, each strand is enclosed in a tube or cylinder of callose, the *callos cylinder*. The whole mass of callose on a sieve plate is usually called *callus*. As the sieve tube ages, the callus becomes more massive. Since each callus cylinder thickens, the strands are constricted and, furthermore, callus bulges and spreads over the surface of the plate until the latter appears completely buried within the callus. The bulging callus masses on both sides of the sieve plate are referred to as *callus plugs*, but it is not known whether they actually plug the sieve plate. Nevertheless, the appearance of the callus plugs indicates that the sieve-tube element has ceased to function. Therefore, the final callus masses developed at the end of the active period of the conducting element are also called *definitive callus*. As it matures the protoplast of the sieve-tube element loses its nucleus, but the cytoplasm is retained until the cell ceases to function. Some studies indicate that this cytoplasm is peculiar: it appears to be wholly permeable. The contents of the vacuole are often slimy and

readily coagulate when the tissue is killed. The so-called *slime plugs* often seen on sieve plates result from such coagulation. The sieve-tube elements of the angiosperms tend to have their sieve plates on the end walls. The sieve plate may cover the wall uniformly or may be broken up into more or less clearly defined sieve areas. The lateral walls show similar sieve areas, but with thinner strands (fig 6, F). *Sieves* of sieve-tube elements are combined into longitudinal series, the *sieve tubes*. Each sieve-tube element is closely associated with one or more slender parenchyma cells called *companion cells* (fig 6, F, Pl I, fig 16). These arise by division from the same mother cell as the sieve-tube element. The sieve cell of the gymnosperms and ferns shows no differences between end and lateral walls. All bear sieve areas of similar nature with rather thin connecting strands. Furthermore, sieve cells are not arranged in vertical superposed series and have no companion cells. Otherwise the sieve cell resembles the sieve-tube element in having callus associated with the connecting strands of the sieve areas and containing no nucleus in the mature protoplast.

The different types of cells characteristic of the plant body are combined into tissues in various manners. For example, only one kind of cell may form a tissue, as in parenchyma or collenchyma tissues (Pl I, fig. 21). The fibres also may be aggregated into a simple mechanical or supporting tissue (Pl II, fig. 7). These are *simple tissues*. In other instances many different kinds of cells are combined to make a *complex tissue*. The best examples of complex tissues are the xylem and phloem, which together constitute the *vascular or conducting tissues* (Pl II, fig. 9). The xylem is concerned principally with the conduction of water and inorganic solutes and contains vessels and tracheids (or only tracheids), xylem fibres of different kinds, xylem parenchyma, and ray parenchyma in different proportions and combinations. The phloem translocates various organic solutes and contains sieve tubes and companion cells (or sieve cells), phloem parenchyma, ray parenchyma and bast fibres. The vascular tissues, notably the xylem, function also as supporting tissues because of presence of fibres. The parenchyma that occurs in these tissues commonly serves for storage of different ergastic substances, particularly starch. The vascular tissues together form an elaborate system, the *vascular system*. Parenchyma is the principal tissue that surrounds and interpenetrates the vascular system. It may be spoken of as *ground tissue*.

Organization of the Plant Body.—The reader is referred to special articles on the anatomy of the lower plants (Thallophyta, ALGAE and FUNGI; and BRYOPHYTES mosses and liverworts) in which the tissues are rather undifferentiated. Suffice it here to mention that both Algae and Fungi range from the simplest unicellular forms with no external differentiation of the body to forms of larger size and greater complexity of organization. The progress in complexity is closely associated with division of physiological labour among the component cells and with the adaptation of the multicellular organism to its environment. But whatever are the various states attained by individual genera, the majority of the cells of the adult bodies of both Algae and Fungi remain alive and the tissues are essentially parenchymatous.

In accordance with the greater complexity in the conditions of life on land for self-supporting plants, considerably more advanced tissue differentiation is exhibited by the Bryophyta, which are mainly terrestrial plants. In a general way this greater complexity consists (1) in the restriction of regular absorption of water to those parts of the plant body which are in close contact with the soil, and (2) in the more regular evaporation of water from the parts exposed to the air. In the higher vascular plants these two principles find their full expression, whereas in the bryophytes water is still absorbed (as, for example, from rain or dew) by the general plant surface. The lowest liverworts have an extremely simple vegetative structure comparable to that of many of the simpler Algae. Since their bodies are small and normally live in damp air, the demands of terrestrial life on them are at a minimum. Their bodies consist of true parenchyma, and the vast majority of the component cells remain alive. Rooting and absorbing threadlike cells (rhizoids) universally occur on

FIG. 7.—SECTION OF THALLUS OF A LIVERWORT (MARCHANTIA).

their lower surfaces in contact with the soil, and considerable tissue differentiation may occur within the body. Thus some possess a distinct assimilative system consisting of branched chains of thin-walled cells packed with chloroplasts and arising from the bases of large cavities directed toward their upper illuminated surfaces (fig. 7). These cavities are completely roofed by a layer of surface cells pierced by pores through which aeration and evaporation are freely maintained. In certain forms in which the body consists of thick midribs and delicate lateral leaflike appendages, strands or bundles of long thick-walled fibrelike prosenchymatous cells with pointed ends are arranged longitudinally within the midribs, which are devoid of special assimilative tissue. The walls of these cells are strongly lignified and are irregularly thick and thin so as to be closely studded by simple pits. The latter are usually arranged in spirals and are often elongated in the direction of the spiral. There is much variety of detail in the differentiation of the tissues of the liverworts, but the general plan of construction resembles that characteristic of the leaves of higher plants.

In the mosses the plant body is generally more elaborate. There is a radially organized supporting and conducting axis (stem) bearing laterally through most of its length thin, flat assimilating and transpiring appendages (leaves). Branched rhizoids are attached to the base of the stem or to parts in contact with the soil. In some instances the stem possesses a special surface or epidermal layer of cells, but usually all the outer layers of the stem (the outer cortex) are composed of brown, thick-walled, lignified, prosenchymatous, fibrelike cells forming a peripheral sclerenchyma (fig. 8). This passes gradually into the thinner-walled parenchyma of the inner cortex. The entire cortex is generally alive, and its cells often contain reserve foods in the form of starch. The centre of the stem, in the forms which live on soil, is composed of a strand of narrow, elongated, thin-walled, unligified, dead cells, which are commonly interpreted as water-conducting elements (*hydroids*). This hydrom strand has in most cases no connection with the leaves, but forms a straight column in the stem and branches locally below the reproductive organs. In the aquatic and semiaquatic forms, and in those mosses which live under conditions of extreme drought, the entire plant surface absorbs water. In all such forms the hydrom strand is either slightly developed or altogether absent. The leaves of most mosses are flat plates, each consisting of a single layer of square or oblong assimilating cells containing chloroplasts. The marginal cells of the plates are frequently produced as teeth, and their walls are thick. The centre of the leaf is often occupied by a midrib consisting of several layers of parenchy-

matous cells elongated in the direction of the long axis of the leaf and poor in chloroplasts. This midrib is usually considered a primitive conductive foliar strand or *leaf bundle*. Hydroids, like those of the central strand of the stem, are frequently associated with this conducting parenchyma, and in some instances are continued into the cortex of the stem as a *leaf-trace bundle* (the anatomically demonstrable trace of the leaf in the stem) (fig. 8). In several forms the leaf trace extends vertically downward for some distance in the outer cortex and ends blindly in a fan-shaped expansion; in others it joins the central hydrom strand so that a connected system is established between stem and leaf. Further differentiation of tissues characterizes the highest family of mosses, the Polytrichaceae. In these, elongated, living, nucleated cells with a thin lining of protoplasm surround the dead central strand and form the phloemlike tissue, commonly called *leptom*. Between the hydrom and leptom is a cylinder of cell layers that may serve for the temporary storage and distribution of carbohydrates, since they sometimes contain an abundance of starch. The underground portion of the stem (rhizome) bears rhizoids and simple scales. The aerial parts bear leaves, each with a simple midrib several cells thick with a strong band of sclerenchyma above, and below a bundle of leptom, hydrom and starch cells, all of which join the central cylinder of the stem. Each midrib bears two wings, one cell thick, while above the midrib is a series of closely set, vertical, longitudinally arranged plates of green assimilative cells.

Vascular Plants.—The greatest anatomical complexity occurs in the vascular plants, which comprise the pteridophyta and the spermatophyta (*q. v.*). The vascular plants are not exactly comparable with the bryophytes for while the body of the latter bears the sexual organs and is called a *gametophyte*, the vascular plant is a sporophyte. Nevertheless the gametophytic bryophyte and the sporophytic vascular plant have similar physiological needs and are both fixed to the soil. The chief new feature in external conformation of the body of a vascular plant compared with that of a bryophyte is the presence of "true" roots, the first formed of which is the downward prolongation of the primary axis of the plant. From this and from various parts of the shoot system, other roots originate. The roots of ferns are structurally simple and uniform compared with those of seed plants, but all manifest a primary plan of construction in direct relation to their normally subterranean life and fixative and absorptive functions, they differ from aerenchyma stems in the characters of their surface tissues, in the absence of the green assimilative pigment chlorophyll, in the arrangement of their vascular systems, and in their mode of apical growth. Great variety in stem and leaf form and structure is shown by the vascular plants.

In spite of the many differences of detail between ferns and seed plants, we can trace, alike in root, stem and leaf, a threefold division of tissue systems, already indicated among the bryophytes, and expressive of the fundamental conditions of evolution of the bulky body of a land plant. Thus there is (1) a specialization of a surface layer of cells that regulates the immediate relations of the plant with its surroundings, while varying in expression in the subterranean and aerial parts. In the former the surface layer is pre-eminently absorptive whereas in the latter it is protective and is concerned with the gaseous interchange of oxygen and carbon dioxide involved in respiration, and in such vital functions as assimilation and transpiration. This surface layer is known as the *epidermis*. Then there is (2) an internal differentiation of conductive tissue, presaged in the bryophytes, and collectively known in the vascular plants as the vascular system. The vascular structures are imbedded in

After W. Loesch, in Lieberkuhn's "Handbuch der Pflanzenanatomie," 6. ed., Bonn, 1890.
FIG. 8.—TRANSVERSE SECTION OF STEM OF A MOSS (MNIMUM). SCLERENCHYMA IN THE OUTER CORTIX. CENTRAL STRAND IN MEDIAN POSITION. BLIND LEAF TRACES IN THE CORNERS.

(3) *fundamental or ground tissue*. The latter may show different distribution and may be combined with other types of tissue. Thus in the axis a *cortex* appears between the epidermis and the vascular tissues and, in the stem, a *pith* usually occurs enclosed by the vascular tissues. In the root the pith is usually absent. In leaves the vascular system is imbedded in parenchyma which is called *mesophyll*. The mesophyll is especially adapted for photosynthesis. Besides absorption, assimilation, conduction and protection, plant tissues serve for support and the storage of food. Thus locally in the cortex, mesophyll and vascular system, special supporting tissues (sclerenchyma) may be developed, and living cells of both the ground tissue and the vascular system may serve for temporary storage of foods and are specialized accordingly. The functions of aeration, assimilation and transpiration are maintained by an extensive system of *intercellular spaces* communicating with the external air.

Meristems.—The different types of cells characteristic of the body of higher plants are alike at the beginning of their existence. They arise together from meristems, and only through subsequent differentiation in development become unlike. A meristem is best defined as a specific region in the plant body where cells are engaged chiefly in division and enlargement. Meristems can be conveniently classified according to position as *apical* and *lateral* meristems. The apex or growing point of the root or shoot illustrates the former type, the *vascular* and *cork cambia* the second. The localization of the areas of cell formation in the plant body distinguishes the plants from the animals, whose parts grow through their whole extent. Also, unlike animals, the higher plants have a continuous formation of new tissues and organs throughout the life of the individual. A meristem is described as undifferentiated embryonic tissue exhibiting juvenile characteristics in contrast with the differentiated or mature tissues that arise from it. Meristems, however, differ morphologically and physiologically from each other and are not sharply separated from those differentiated tissues that retain protoplasts at maturity, particularly the parenchyma tissue. The living mature tissues are potentially meristematic, and resume meristematic activities when appropriately stimulated. Furthermore, cells of a given meristematic area may vary among themselves in many features.

Apical Meristems.—These meristems are usually composed of approximately isodiametric cells with prominent nuclei. The cytoplasm is often dense but may be also conspicuously vacuolated. The dense cells have many small vacuoles dispersed in the cytoplasm. The walls are commonly thin, and the cells are closely packed without intercellular spaces among them. The architecture of the apical meristems varies in different groups of plants. In most ferns, in the horsetails and in some other vascular plants, all tissues of the stem and root are derived from single *apical cells* located at the apices of these organs (Pl. I, fig. 6). The apical cell, which may be termed also *initial cell*, is usually tetrahedral in shape. Its base occupies the surface of the apical mound of tissue, and the apex points inward. By definite and regular divisions of such a cell, a mass of still undifferentiated cells is produced immediately below the apex that is continuously occupied by a residual apical cell. From these undifferentiated cells the different tissues sooner or later arise by further growth, divisions and differentiation. In the seed plants a few to many cells at the apex of shoot and root initiate the body tissues, and these cells function in different manners. In angiosperms shoots one or more superficial layers and a central core of the apical mound have independent initials (Pl. I, fig. 2). The peripheral layers (tunica) are characterized by surface growth, that is, anticlinal divisions predominate. The underlying core (corpus) shows divisions in all planes and thus grows in volume. The two zones are interdependent and their extent and behaviour fluctuate. They are not at all specific as to the tissues that originate from them. The peripheral zone may be concerned with the production of the epidermis only, or it may give rise to one or more of the underlying regions. Similarly, the central zone may produce pith only or also the vascular tissues and even the cortex. In the gymnosperms a peripheral and central zone may

also be distinguished but here they appear to be more interdependent than in the angiosperms: a superficial group of initials divide anticlinally and periclinally and give rise to both the external and the internal cells of the apical mound (Pl. I, fig. 9).

The root and shoot apices differ from each other in several fundamental features. The shoot apex is concerned with the production of the lateral organs of the stem axis, that is, the leaves; the root apex produces no lateral organs; the lateral roots arise some distance from the apex and not superficially (like the leaves) but in the deeper layers of the axis. Thus the lateral roots have an *endogenous* origin in contrast to the leaves, whose origin is described as *exogenous*. The shoot apex is exposed to the outside and cuts off cells only toward the axis (Pl. I, figs. 1, 2). The root apex is covered with a protective tissue, the *root cap*, produced by cells that are cut off away from the axis of the root (Pl. I, figs. 7, 8). Thus, strictly speaking, the apical meristem of the root is *subterminal*, whereas that of the shoot is *terminal*. The initial cells of the root apex of angiosperms are commonly arranged in two or more tiers. One tier may form the root cap, epidermis and cortex, the other the central cylinder containing the vascular tissues. In other species the root cap arises from a separate initial layer (calyptragen), the cortex and epidermis from another, the central cylinder from a third; or the epidermis and root cap have common origin (Pl. I, fig. 8). Sometimes all four root regions arise from separate sets of initials. In some roots the apical meristem appears generalized and shows no distinct tiers of initials. The study of a root having separate initials for the various regions of the root axis might give the impression that the regions are predetermined in the apical meristem. Such a view has been actually held and the supposedly independent meristematic regions, the *histogens*, have received special names: *dermatogen*, *periblem* and *plerome*, the precursors of the epidermis, cortex and central cylinder, respectively. Since in some roots, and apparently in all shoots, the regions of the axis cannot be traced back to separate sets of initials, the deterministic scheme of apical structure cannot be accepted.

The Primary Plant Body.—The apical meristem of shoot and root produce a complete plant body with all its vegetative and reproductive organs. This body is spoken of as the primary body, and the tissues composing it as *primary tissues* in distinction from the secondary body or *secondary tissues* that are later added to the primary body by the two lateral meristems, the vascular cambium and the cork cambium. The primary tissues result from progressive differentiation of the cell masses produced by the apical meristems, and the latter may be traced back to the embryo and the zygote. As previously stated, the various tissues or regions of the plant body do not appear to be predetermined in the initial regions of the apical meristems. The first certain evidence of tissue differentiation occurs in the subapical regions. Here some cell masses show speeded up vacuolation of their protoplasts, others remain dense somewhat longer, but divide largely by longitudinal walls and soon become longer than wide. The more highly vacuolated parts of the subapical meristem later differentiate into the cortex and pith (if the latter is present) and are termed the *ground meristem*; the meristem part composed of the dense elongated cells is the precursor of the primary vascular system called *procambium*. It forms the primary xylem and primary phloem. A young plant organ, or part of it, composed of these partly differentiated but still meristematic tissues, is covered on the outside by a discrete meristematic layer, the *protoderm*, which later matures into the epidermis. These three meristems, the ground meristem, the procambium, and the protoderm, as well as the apical meristems, are the *primary meristems* whereas the two cambia are *secondary meristems*.

Epidermis.—The epidermis of the aerial stems and leaves is primarily a covering layer which protects against harm from loss of water and against mechanical injury. It usually consists of a single layer of living cells devoid of chloroplasts, and with thickened and cuticularized outer walls (Pl. I, fig. 11). At intervals the epidermis is interrupted by small pores (stomata) leading from the outer air to the system of intercellular spaces in the underlying tissues, and serving for gaseous interchange between

these tissues and the outer air. Each stoma is surrounded by a pair of peculiarly modified epidermal cells called *guard cells* (Pl. I, figs. 11, 15), which possess chlorophyll and open and close the pore in accordance with the changes in turgidity. The stomata of leaves are generally much more numerous in the lower epidermis than in the upper, and may be absent in the latter. They are often situated at the bottom of pits in the leaf surface. Thus transpiration is checked by the creation of a still atmosphere in the pit above the pore. Such an arrangement of the stomata is found especially in plants adapted to growth in regions where the supply of available water is deficient. In some angiosperms the epidermis is doubled or trebled by tangential divisions in the original layer, resulting in a *multiple epidermis*, which functions as a water-storage tissue. In many vascular plants epidermal organs, known as *hydathodes*, are developed, especially on foliage leaves, and serve for excretion of water in liquid form.

Hairs and Scales.—The epidermis of many species of vascular plants bears hairs or scales of varied form and function. The simplest hairs consist of single elongated cells projecting above the general surface of the epidermis, while others consist of simple or branched cell-chains. The more complex scales are flat plates of cells commonly inserted on mounds or stalks, and may be placed parallel to the leaf surface or projecting directly from it. In other instances the hairs are glandular and excrete ethereal oils, or they may be stinging, as in the common stinging nettle, in which the top of the hair is brittle, and when touched penetrates the skin, breaks, and injects formic acid into the slight wound thus formed. In many plants both hairs and scales are shed before the stems and leaves are mature, in others they are retained throughout the life of the plant.

Epidermis of Root.—The epidermis of the root is fundamentally different from that of the stem or the leaf. In relation to its normal function of water absorption its cell walls are not cuticularized, and usually remain thin. The absorbing surface is increased because many of the cells expand their outer walls into tortuous, delicate, uncellular tubes (root hairs) which aid in anchoring the root, and readily absorb the surface films of water from the soil particles. A root hair thus corresponds in function with a rhizoid of a bryophyte. The hairs are normally definitely restricted to a more or less definite zone of the root a little removed from the growing root tip. At the lower limit of this zone hairs are constantly being formed as the root advances in the soil, while at the upper limit they have passed maturity, are dying and are being destroyed. Thus beyond the zone which at any moment bears living absorbing hairs the epidermis is extensively or completely destroyed, and its place is taken by the immediately subjacent cortical layer, which is not absorptive, but becomes protective like the epidermis of the stem or leaf.

The Cortex.—The cortex consists primarily of living parenchyma, but its differentiation may be extremely varied, and in the complex bodies of vascular plants its functions are varied and may be modified. The cortex of a young stem is usually green, as its cells possess chloroplasts, and a fine system of intercellular spaces communicates with the external air through stomata (Pl. I, fig. 11). With age the inner cortical layers may lose their chlorophyll and become storage tissue, and the outer layers may be extensively modified. In many ferns and lower vascular plants the mature outer cortical layers of the stem and root are hard *sclerenchyma* with thick brown walls, but in flowering plants, while the stems are still slender, the cells of the outer cortical layers elongate and become cylindrical or spindle-shaped and develop localized cellulose thickenings, that is, this part of the cortex differentiates as *collenchyma*. It provides peripheral support for the growing stem, and as its cells are alive, is open to later modifications with changing conditions in stems that undergo annual increase in girth. On the other hand *sclerenchyma* is commonly dead, and provides a more rigid but usually unmodifiable supporting tissue. Its adequacy will be evident for stems such as those of modern ferns, which do not increase annually in girth. Less commonly, scattered cells or cell groups which increase little in length may become stone cells, with irregularly but inordinately thickened hard walls. Various secretory

cells may occur in the cortex, usually lining cavities or canals which arise through a breakdown of certain cells (oil cavities in a citrus stem or fruit) or through enlargement of intercellular spaces (resin canal in pine stem). The cortex of the stem shows more modifications than that of the root. In the dicotyledons the root cortex commonly remains entirely parenchymatous and is early shed in connection with secondary growth, whereas in the monocotyledons and in the ferns it is more or less sclerotized at maturity.

Endodermis.—The innermost layer of the living cortex investing the centrally located vascular system of the axis may be early and peculiarly modified as a continuous cylinder called the endodermis. Throughout its extent the endodermal cells are in close contact, so that the system of intercellular spaces in the cortex is not continued into the central cylinder of conductive tissue. In the absorbing region of angiospermous roots the endodermis shows a very characteristic structure. A band of wall material impregnated with fatty substances and lignin extends completely about the inner surface of the lateral longitudinal and end walls of each cell. These bandlike thickenings of the wall are known as *Casparian strips* (Pl. I, fig. 10). This kind of endodermis is thought to play a role in the regulation of the transfer of solutes from the cortex into the vascular system; the presence of the fatty substances in the Casparian strip and the firm connection between the strip and the cytoplasm of the cell apparently force the soil solution to move through the cytoplasm and be subjected to the protoplasmic control of the endodermal cells. In older roots that cease to absorb the endodermis may develop thick lignified walls (Pl. II, fig. 10); or it is torn and shed because of secondary increase in thickness of the central cylinder. The stems of seed plants rarely show peculiar morphologic characteristics in the innermost layer of the cortex. In the youngest part of the stem this layer is commonly differentiated as a *starch sheath*, which may be regarded as an equivalent of the endodermis. It is rich in starch and forms a continuous layer around the vascular system. In the more mature regions of the stem starch is absent. In most ferns the endodermis appears as a morphologically distinct layer throughout the stem and the root. Casparian strips and more generally suberized endodermal cells have been observed in this group of plants.

Mesophyll.—The mesophyll of the leaf is primarily concerned with the fundamental function of carbon assimilation, and to the active performance of this function the maximum exposure of living parenchymatous tissue containing chloroplasts is necessary. Thus the mesophyll is essentially a green expanse of thin-walled parenchyma and is penetrated by a large and elaborate system of intercellular spaces which serve at one and the same time for the promotion of transpiration and respiration. The pathways for the gases between the mesophyll and the outer air are the stomata which are in direct communication with the ample system of intercellular spaces in the mesophyll. The lower layers of the mesophyll are loosely arranged as spongy tissue with extensive intercellular spaces (Pl. II, fig. 12). This is the main transpiring tissue of the leaf, and in it chloroplasts may be comparatively few. It is protected from direct illumination and is at the same time liable to over-evaporation. The main assimilating tissue, on the other hand, is under the upper epidermis and it is well illuminated, its cells are densely packed with chloroplasts, and are commonly oblong, with their long axes perpendicular to the leaf surface. The intercellular spaces are here narrow, as between sticks in a bundle, and are in open communication with the intercellular spaces in the spongy tissue below. By reason of its resemblance to the boards in a fence, when viewed in a transverse section of the leaf, this portion of the mesophyll is called the *palisade tissue* (Pl. II, fig. 12). Leaves with blades held in a vertical position commonly possess palisade tissue on both sides or have little or no distinction in the form and arrangement of the cells of the mesophyll (Pl. II, fig. 13), since there is no difference in the illumination or other external conditions, while cylindrical or approximately cylindrical leaves may have palisade tissue all around. The leaves of shade plants have little or no differentiation of the palisade tissue. In fleshy leaves, which

contain a great bulk of tissue in relation to their chlorophyll content, the central mesophyll contains little or no chlorophyll and may consist of water-storage tissue, while locally a layer or mass of subepidermal cells may be thick-walled and fibrous.

The cortex of the leaf stalk or petiole is transitional in structure to that of the stem and leaf blade. The petiole is traversed by one or more vascular strands connected below to the central conductive system of the stem, and leading forward in the leaf blade to a complex system of minor strands which ramify the mesophyll in the plane of junction of the spongy and palisade tissue. The layer of mesophyll immediately investing each bundle usually has the form of a special parenchymatous sheath of elongated cells (Pl II, fig. 13). In dicotyledons the sheath cells commonly have fewer chloroplasts than the rest of the mesophyll. The *bundle sheaths* are considered important in the conduction of carbohydrates from the assimilative cells to the conductive strands and in the supply of water from the latter for transpiration. Their function is thus considered in some measure comparable with that of the endodermis.

Vascular System.—Among the most striking characters of vascular plants is the possession of a double (xylem-phloem) conducting system, such as has been presaged in the higher mosses, but with more sharply defined and specialized features. This is the vascular system, and associated with it are other tissues consisting of parenchyma and sclerenchyma. The primary vascular system together with the associated tissues is known as the *stele system* (from the way in which in its simpler forms it traverses the whole axis of the plant as a column). When it is remembered that the moss plant is a gametophyte while the vascular plant is a sporophyte, it will be realized that the vascular system of the latter is not the result of elaboration of the conductive system of the former, but that these vascular systems are more readily interpreted as somewhat similar products of differentiation in plants adapted to life on land.

Arrangement of the Vascular System.—In the vascular system the xylem and phloem are nearly always found in close association in strands or *bundles* (Pl. I, fig. 14), but as is to be expected the arrangement of such bundles is by no means stereotyped either in the given plant group or in the different parts or members of the plant body. A connected vascular system penetrates, however, the entire body. When the vascular system of the axis appears in the form of a solid rod, with a core of xylem ensheathed by phloem, it is termed *protostele* (Pl. II, fig. 1). Usually a discrete parenchymatous layer, the so-called *pericycle*, surrounds the phloem, then follows the endodermis. The evidence from comparative anatomy and palaeobotany indicates that protostele is the primitive type. It occurs in both the stem and root of many lower vascular plants, but is restricted to the root of seed plants (Pl. I, fig. 19). In the advanced ferns the vascular system of the juvenile stem is a solid protostele, but that of the more bulky portions of the adult plant shows a different arrangement. If the xylem core is not solid but contains parenchyma (pith or medulla), the stele becomes a medullated protostele or *siphonostele* (fig. 9, A, Pl. II, figs. 2, 3). In the protosteles the vascular system is not interrupted, at least not markedly so, where a vascular bundle, the leaf trace, diverges to a leaf. Siphonosteles usually show breaks in the continuity of the vascular tissues above the departure of a leaf trace, these breaks being called leaf gaps. The gaps are filled with parenchyma, which connects the pith with the cortex. In cross sections of internodes such a stele appears as a continuous circle but shows breaks in the nodal region. If the leaf gaps overlap in their longitudinal extent in a siphonostele vascular system, the stele is a *dictyostele* which, in cross section of both nodes and internodes, appears composed of several portions (fig. 9, B). This kind of dictyostele may be found, for example, among ferns. In a dictyostele breaks other than leaf gaps—the parenchymatous *medullary rays*—may be present (Pl. II, fig. 5). A stele of this type should be visualized as a tubular network, the meshes representing the vertical leaf gaps and parenchymatous rays. The stems of seed plants typically have such steles. Thus the vascular system of the axis (root and stem) commonly has the shape of a solid rod or

FIG. 9.—DIAGRAMS OF A SIPHONOSTELE, A, AND A DICTYOSTELE, B. TISSUES OTHER THAN THE VASCULAR ARE SHOWN IN C IN CONNECTION WITH A DICTYOSTELE.

a tube with or without perforations. The leaves, if small as in the lower Tracheophyta (e.g., *Selaginella*, *Equisetum*) or the conifers (e.g., firs), have a very simple system which typically consists of one unbranched vein. The large-leaved ferns have complex systems of bundles in the petioles and rachises, with branches given off into the pinnae. The angiosperms commonly have rather large leaves with complex vascular systems (see below, *Vascular System of Leaf*). The xylem and phloem show two types of disposition in siphonosteles. If the phloem appears only on the outside of the xylem the stele is *ectophloic*, if on both sides, *amphiphloic*. If the ectophloic stele is a much dissected dictyostele the individual strands making up such a stele are *collateral bundles*, having xylem on one side, phloem on the other. The component parts of an amphiphloic dictyostele are *bicollateral bundles* having phloem on both sides of the xylem.

The Vascular System in the Stem of Seed Plants.—In this group of plants distinct vascular bundles traverse the axis and anastomose with each other (very much dissected dictyostele). At certain intervals one or more bundles diverge into a leaf, and it appears that all bundles of the stem are directly or indirectly related to the leaf bundles. In other words, the vascular system may be regarded as made up of leaf traces and their fusions. The number of leaf traces to a given leaf varies. Common numbers are one, three and many. If the trace is single only one leaf gap or *lacuna* is associated with the given leaf and the condition is spoken of as *unilacunar*. If there is more than one trace the node may show a *trilacunar* (three gaps) or a *multilacunar* (more than three gaps) condition. The trilacunar node appears to be primitive in the angiosperms. The development of axillary buds further complicates the vascular anatomy of the node. The vascular bundles connecting the bud with the vascular system of the main axis are known as *branch traces*, which are usually two in number. *Branch gaps* or parenchymatous areas in the vascular system of the main axis occur above the divergence of the branch traces. In the gymnosperms and dicotyledons the vascular bundles are usually arranged in one circle, with parenchymatous rays separating the bundles from each other. The monocotyledons typically possess large leaves with broad sheathing bases containing numerous bundles. Therefore the number of bundles present at any given level of the stem is high. They are arranged in more than one circle or are scattered in a definite, though not superficially obvious, order throughout the cross-sectional area of the stem so that the delimitation of cortex and stele is difficult or impossible (Pl. II, fig. 4). The bundles are surrounded by large-celled ground tissue and around each bundle there is a fibrous investment or sheath (Pl. I, fig. 14).

Vascular System of Root.—The stele of the primary root of a gymnosperm or angiosperm is of radial structure (Pl. II, figs. 10, 11). There are usually two or more xylem strands radially alternating with as many phloem strands, and the first formed xylem groups (protoxylem) are peripheral (Pl. I, fig. 19). Depending on the number of the xylem strands, the root is called

diarch, triarch, tetrarch or polyarch. The centre of the stele is either solid xylem or is pithed, and sclerotic cells are in the ground tissue. Thus the vascular system of the root in seed plants is much simpler than in the stem. It forms a protostele, though not of the most primitive kind; the phloem does not completely ensheath the xylem but appears in strands alternating with the protoxylem points.

Vascular System of Leaf—In the leaf of the average seed plant the vascular tissue appears as a number of branching or approximately parallel, and usually anastomosing, strands. Above and below the larger strands the leaf parenchyma is raised so as to produce the so-called *veins*. The vein system is typically very elaborate, and the bundle system is concentrated in the petiole as the tributaries of a river are massed in the main stream. The leaf bundles are usually collateral (the phloem being turned downward and the xylem upward), and the whole bundle may be protected above and below by fibrous cells (Pl. II, fig. 13). As the bundles are followed toward their blind endings in the mesophyll the fibres first disappear, the sieve tubes are replaced by narrow elongated parenchyma which also disappears before the end of the bundle is reached. The bundles usually end in short or long spiral or reticulate tracheids covered by the bundle sheath.

Ontogeny of the Vascular System—The primary vascular system in the various organs of the plant is first delimited in the form of a meristem called *procambium*. The latter assumes similar aspect as the mature vascular system with its continuities and interruptions, gaps, traces, bundles and other details. But all parts of the procambial system are short. The elongation of these parts is one of the phases in the maturation of the procambium into the vascular system. In a given transverse section of the procambium the vascular elements differentiate not all at once, but gradually. The first primary xylem elements (protoxylem) may appear on the periphery of the xylem system, and the subsequent primary elements (metaxylem) toward the centre. Such order of differentiation is spoken of as *centripetal* and the xylem of this kind is *exarch*; or the protoxylem occupies the innermost position in the xylem system and the further xylem differentiates *centrifugally*. Such primary xylem is *endarch*. The first phloem is termed *proto-phloem*; then follows the *meta-phloem*. The phloem located on the outside of the xylem differentiates centripetally. The internal phloem, as in an amphiphloic siphonostele, differentiates centrifugally. A good example of exarch xylem is found in the roots of seed plants. Here the starting points of xylem differentiation, the *protoxylem poles*, occur on the periphery of the stele and alternate with the *proto-phloem poles* (Pl. I, fig. 19). Both metaxylem and meta-phloem differentiate toward the centre of the root, but the phloem remains essentially peripheral, whereas the metaxylem frequently reaches the centre. The xylem in the stems of seed plants is typically endarch. The protoxylem occurs on the periphery of the pith in each major subdivision of the axis. Opposite each protoxylem strand on the periphery of the stele is the proto-phloem bundle. The meta-xylem and meta-phloem differentiate toward each other, that is, the xylem shows a centripetal, the phloem a centripetal order of development. The leaf bundles commonly show the same order of differentiation as the stem bundles.

The longitudinal course of differentiation in the root is from the more mature toward the younger parts of the root, that is, the differentiation is centripetal. In the stem, however, xylem and phloem as far as known differentiate each other in their initial course. The phloem differentiates centripetally from the lower regions of the axis toward the apex and more the leaf primordia, whereas the xylem is initiated at the base of the leaves or in the leaves and then differentiates toward the apex of the elongating leaf and downward (basipetally) into the axis toward the junction with the mature xylem below.

The primary xylem is simpler in structure than the secondary. The protoxylem contains only one or two kinds of tracheids or vessels (commonly with annular and spiral secondary thickenings) and some parenchyma. The metaxylem shows greater variety of elements and often contains fibres. The primary phloem also is simpler than the secondary. The protoxylem and proto-

phloem mature before the organ in which they occur completes its elongation. Since the water-conducting elements are dead at maturity and the sieve tubes or sieve cells have enucleated protoplasts, these vascular elements cannot respond with growth to the continued division and elongation of the adjacent tissues. For a while the protoxylem and proto-phloem elements, which have no rigid walls, are passively stretched, then they are torn and more or less completely obliterated while new conducting elements differentiate to take the place of the old ones. Consequently in mature plant organs the proto-phloem and protoxylem may appear much modified as compared with their original state. This is particularly true of the proto-phloem in which fibres (bast fibres) or collenchyma-like cells often differentiate after the obliteration of the conducting elements. The fibrous or collenchymatous proto-phloem appears like a region very distinct from the rest of the phloem and has often been called the *pericycle*. The metaxylem and meta-phloem remain longer intact, though they too become functionless when secondary vascular tissues are formed. In plants having no secondary growth, the metaxylem and meta-phloem are the main conducting tissues of the mature plant.

Laticiferous Tissue—In certain families of Angiosperms there are peculiar tissues that do not occur in the ferns and their more primitive relatives. Such, for example, is the laticiferous tissue found in Compositae and Euphorbiaceae, which appears in the form of long, usually branched tubes penetrating the other tissues of the plant in a general longitudinal direction. The tubes possess a delicate layer of protoplasm with numerous nuclei lining the walls, whereas the interior of the tube (corresponding with the cell vacuole or cavity) contains a fluid called *latex*, consisting of an emulsion of fine granules and drops of various substances, suspended in a watery medium, in which other substances (salts, sugars, rubber-producers, tannins, alkaloids and various enzymes) are dissolved. Of the suspended substances, grains of caoutchouc, drops of resin and oil, proteid crystals and starch grains may be mentioned. Of this varied mixture of substances some are undoubtedly *plastic* (i.e., of use in constructing new plant tissue), while others are apparently end-products of metabolism, secreted within the plant body. The latex may be milky in appearance or nearly colourless. The use of certain plants as rubber producers (notably *Hevea brasiliensis*, the Para rubber tree), depends on the property of coagulation of the latex. The trees are regularly tapped and the coagulated latex which exudes is collected and worked up into rubber. Opium is obtained from the latex of the opium poppy (*Papaver somniferum*), which contains the alkaloid morphine.

Laticiferous tissue is of two kinds: (1) laticiferous cells, which branch but do not anastomose, and the apices of which keep pace in their growth with the other tissues of the plant (Apocynaceae and most Euphorbiaceae); (2) laticiferous vessels, which are formed from rows of actively dividing (meristematic) cells. The end walls of these cells break down so that a network of laticiferous tubes arises (*Papaveraceae, Illicaceae*). In some plants, as in *Linum* and in the Convolvulaceae rows of cells with latexlike contents occur but the walls separating the individual cells do not break down.

Cambium and Secondary Growth—Most of the modern ferns, horsetails and briaraceous monocotyledons, and many of the annual dicotyledons, are composed of primary tissues only. The gymnosperms and many dicotyledons, particularly the arborescent, have in roots and stems large amounts of secondary vascular tissues added to the primary so that the axis becomes many times thicker than it was in the primary state. These tissues are formed by the *vascular cambium* (Pl. I, fig. 20). In the stems this meristem arises partly from the procambial cells that remain in meristematic state after the primary xylem and phloem of the bundles mature, and partly from the ray and gap parenchyma cells located between the bundles. Because of this double origin it is customary to speak of *fascicular cambium*, if it arises within the bundle, and *interfascicular*, if it is formed between the bundles. The two, however, form one continuous meristem, circular in cross section. In the roots, the cambium arises first on the inside of the phloem strands. Then these strips of cambium be-

PLANTS AND PLANT SCIENCE

come connected with each other by cambial cells that arise within the parts of pericycle located outside the protoxylem poles. Thus in both the stem and root a continuous cambial cylinder is formed, which produces secondary xylem toward the centre of the axis, secondary phloem toward the periphery.

It is difficult to indicate precisely when procambium becomes cambium. Generally, one might say that the procambium exists and produces the primary vascular tissues as long as the primary organ is still elongating by continued cell division and cell enlargement in the differentiating primary tissues. After this growth ceases, the remaining vascular meristem assumes the characteristics of the cambium. The latter thus functions in the part of the body that attained its final length. Therefore, if the elements produced by the cambium elongate, they do so not in harmony with the adjacent tissues but by a kind of sliding growth in which the elongating cell intrudes among other cells. In a wide range of dicotyledons and gymnosperms the vascular cambium shows certain common characteristics. It is composed of two kinds of initials: (1) the elongated, prosenchymatous, sometimes spindle-shaped, fusiform initials, and (2) the prismatic parenchymatous ray initials. Both kinds of initials are highly vacuolate. The fusiform initials form such elements as tracheids, vessels, fibres, wood parenchyma and sieve tubes, that is, vascular elements that are disposed vertically in the axis of the plant. The ray initials are points of origin and propagation of the radially disposed xylem and phloem rays. There is only one layer of initials around the circumference of the axis but the immediate products of this layer cannot be distinguished anatomically from the initials. The initials and their nearest products (the xylem and phloem mother cells) together form a few-layered cylinder of thin-walled vacuolate cells between the xylem and the phloem.

Through secondary growth the primary xylem is buried in the centre of the stem or root, while the primary phloem is pushed outward. The cambial cylinder itself moves outward because of the accumulation of secondary xylem inside of it. As it does so, it also increases in circumference. The divisions that add to the xylem and phloem are tangential, but those that cause the increase in girth of the cambial cylinder are either radial longitudinal (anticlinal) or oblique radial divisions, followed by such elongation of the daughter cells that they appear to slip past each other and eventually lie side by side, at least part of their length.

Secondary Vascular Tissues.—The secondary xylem and phloem are highly complex tissues composed of many kinds of cells. As in the cambium, two systems of cells may be distinguished in the secondary tissues, the radial or transverse formed by rays, and the vertical or longitudinal made up of various cells having their long axes parallel with the axis of the organ (fig. 10). The xylem and phloem rays are usually parenchymatous, but may contain ray tracheids in the xylem of gymnosperms. The longitudinal system of the phloem contains sieve cells, phloem parenchyma and fibres in the gymnosperms; sieve tubes with companion cells, phloem parenchyma and fibres in the dicotyledons. The vertical system of the xylem in gymnosperms may contain only tracheids or also fibres and xylem parenchyma. The dicotyledons have a more complex longitudinal system, the complexity varying in different groups. Vessels, tracheids, several kinds of fibres, and xylem parenchyma are common components. The patterns of distribution of the different elements of the secondary phloem and xylem vary greatly and serve as useful criteria in the recognition of relationships among plants.

The secondary vascular tissues in roots and stems are fundamentally similar, but often the root contains a higher proportion of storage parenchyma. The fascicular and interfascicular cambium portions of stems may produce essentially the same kinds of tissues, as in most trees (Pl. II, fig. 8); or the interfascicular cambium forms only ray parenchyma, as in woody vines (Pl. II, fig. 7). In the former case the secondary xylem and phloem form continuous cylinders; in the second the vascular system is broken up into blocks or large strands, each associated with a primary xylem strand next to the pith. Similarly in the roots, the cambium arising in the pericycle may form parenchyma only; or the cambium produces a continuous vascular cylinder (Pl. II, fig. 6).

Annual Rings.—In those plants whose annual activity is interrupted by a regular winter or dry season the limit of each year's increment of secondary wood is marked by a more or less distinct line which is produced by the sharp contrast between the elements formed in the late summer of one year and those produced in the spring of the next (Pl. II, fig. 8). Frequently large vessels are produced by the cambium in the spring, while as summer advances the vessels formed are narrower, and then fibres with greatly reduced cavities arise. In gymnosperms containing no vessels the tracheids formed in the spring have much thinner walls and wider lumina than those produced during the summer. Thus in a single season of cambial activity a rough outward progression may be traced in the secondary wood of that season from wide vessels or tracheids to narrow fibres, beyond which the transition to the wide vessels or tracheids of the succeeding spring is sudden. Each zone thus recognized in a cross section of the stem is called an annual ring, and the lines of separation of successive rings mark the temporary halting places of the cambium at the end of successive seasons.

Sapwood and Heartwood.—The older wood of large trees, forming a cylinder in the centre of the trunk, frequently undergoes marked changes in character. The wood parenchyma and medullary rays die, and the walls of all the cells often become greatly hardened, owing to the deposit in them of special substances. Wood thus altered is called heartwood or duramen, as distinguished from the younger sapwood or alburnum, which is nearer the cambium, carries on the active function of conduction, and retains its parenchymatous cells in life. The heartwood ceases to be of any use to the tree except as a support, and because of its dryness and hardness is much used for industrial purposes.

Phellogen and Periderm.—The secondary increase of xylem and phloem involves an outward movement of the primary phloem and of all the elements which surround the latter. The cortex, and particularly the epidermis, must accommodate for this movement, either yielding passively to a limit and being injured or

destroyed by the outward pressure, or being to some extent modified so as to persist. Mostly the epidermis is unable to maintain the active radial division of its cells necessary for such expansion, is soon stretched to its limit, dies and is destroyed. Extensive radial division in the cortical cells is progressively less essential as the inner cortex is followed inward, and as a rule, by a combination of radial and tangential divisions, the integrity of the cortex is maintained. Toward the periphery of the cortex, and commonly by modification of its outer layer, a secondary meri-

The sugars, however, appear to be entirely restricted to the vacuoles, as is also true of a part of the minerals and some of the nitrogenous compounds, especially the amino acids. The properties of protoplasm are clearly as much a function of its ultimate physicochemical organization as of the specific compounds of which it is composed. A number of the properties of protoplasm are similar to those of hydrophilic colloids. Among these are its elasticity, its variable viscosity, its imbibitional capacity, its capacity for reversible gelation, and the fact that its physical state may be markedly influenced by mechanical disturbances, high or low temperatures, or certain concentrations of electrolytes. Protoplasm, therefore, appears to have the organization of a hydrophilic colloid, but its structural and dynamic complexity far transcends that of nonliving hydrophilic systems such as agar or gelatin sols or gels. William Seifriz and others postulate that protoplasm has a basically fibrillar structure, the submicroscopic fibrils (composed largely or entirely of complex proteins) overlapping and interlocking through molecular side chains within an aqueous medium. Electrolytes, carbohydrates, lipids and other constituents of the system may be dissolved or dispersed in the aqueous medium, dissolved in water held within the fibrils, or adsorbed at interfaces within the system.

Protoplasmic Streaming—In many plant cells the protoplasm is in active motion. In the simplest cases this movement consists of a rotation around the inner surface of the cell wall. Rates of cytoplasmic streaming may range up to at least 19 in per hour. Protoplasmic streaming (cytosis) is accelerated by increases in temperature up to the point at which injury occurs, and is retarded at lower temperatures, ceasing just above freezing. Cytosis also ceases in the absence of oxygen. The exact mechanism of protoplasmic streaming is unknown.

Permeability—Unlike the cell walls, which in most living cells are quite freely permeable to water and solutes, the cytoplasmic layer is more permeable to some substances than to others. In other words, cytoplasm is differentially permeable. This property of differential permeability resides largely in the surface layer of the cytoplasm in contact with the cell wall (plasmalemma), and the surface layer in contact with the vacuole (tonoplast). The cytoplasmic layers are usually relatively permeable to water and to certain solutes such as dissolved gases, and to some types of organic compounds. On the other hand, they are usually much less permeable to sugars and mineral salts. The permeability of the cytoplasmic membranes is a variable property, however, and under certain conditions solutes which ordinarily penetrate through these membranes slowly or not at all may enter or leave cells very rapidly.

Osmotic Relations of Plant Cells—The osmotic pressures of plant cell saps mostly lie within a range of 5–40 atm. (atmospheres). Much higher values occur in some halophytes, the maximum on record being 202.5 atm in the leaf cells of saltbush (*Atriplex confertifolia*). The osmotic pressures of the cells of a given plant tissue may vary considerably with environmental conditions and the metabolic status of the cells; more or less regular diurnal or seasonal variations in osmotic pressure occur in the cells of many tissues.

If a flaccid plant cell (i.e., one in which the cell sap exerts no pressure against the encompassing protoplasmic layer and cell wall), is immersed in pure water, inward diffusion of water (osmosis) occurs into the cell sap. Diffusion of the water takes place because the diffusion pressure of the water in the cell sap is less than that of the surrounding pure water by the amount of its osmotic pressure. If the osmotic pressure of the cell sap is 12 atm., the diffusion pressure of the water in the cell sap is 12 atm., less than that of pure water at the same temperature and under the same pressure. The lower diffusion pressure of the water in the cell sap results from the presence of solutes. As water enters the cell it exerts a *turgor pressure* against the protoplasm and cell wall, a pressure which also prevails throughout the mass of water within the cell. If the cell wall is elastic, as it usually is, some expansion will occur in the volume of the cell. As diffusion of water into the cell continues, turgor pressure gradually increases until eventually it is equal to the final osmotic

pressure of the cell sap. At this point of dynamic equilibrium the diffusion pressures of the water in the cell sap and the surrounding water are equal, and the number of molecules entering the cell exactly equals the number passing out of the cell per unit of time. Subjection of water to an imposed pressure increases its diffusion pressure by the amount of the imposed pressure. In this example, disregarding the usually small effect of sap dilution as the cell expands, the diffusion pressure of the water in the cell sap is reduced 12 atm because of the presence of solutes (the osmotic pressure is the index of this effect) and raised 12 atm by the turgor pressure; hence its equilibrium diffusion pressure is the same as that of the pure water bathing the cell. If the same cell in a flaccid condition is immersed in a solution with an osmotic pressure of 5 atm., inward diffusion of water occurs but does not continue as long as in the preceding example. Disregarding dilution, dynamic equilibrium is attained when a turgor pressure of 7 atm prevails within the cell, because at that point the diffusion pressure of the water in the cell sap and that of the water in the solution are equal. As exemplified in the preceding examples, the effective physical quantity determining the direction of osmotic movement of water from cell to cell in plants or between a cell and an external solution is the *pressure deficit* of the water, which is equal to the osmotic pressure of the water less the turgor pressure to which it is subjected. Commonly used synonyms for this term are diffusion pressure deficit, turgor deficit, effective osmotic pressure, and suction tension. In an unconfined solution the pressure deficit is equal to its osmotic pressure, since there is no turgor pressure. The pressure deficit and turgor pressure of a plant cell vary reciprocally, in the fully turgid cell the pressure deficit is zero and the turgor pressure equals the osmotic pressure; in the fully flaccid cell the turgor pressure is zero, and the pressure deficit is equal to the osmotic pressure.

In some kinds of cells water may, under certain conditions, pass into a state of tension (negative pressure). In such cells the pressure deficit is equal to the osmotic pressure plus the tension imposed on the water, and sometimes far exceeds the osmotic pressure of the cell sap. As between two plant cells, osmotic movement of water always occurs from the cell of lower to the cell of greater pressure deficit unless some interfering or offsetting condition or mechanism prevents or counteracts such movement. Movement of water in plant tissues commonly occurs from cell to cell along pressure deficit gradients. The osmotic pressure, pressure deficit, and turgor pressure are called the *osmotic quantities* of plant cells, all three of these physical quantities are necessary in any critical evaluation of the water relations of cells.

Plasmolysis—If an at least partially turgid plant cell be immersed in a solution with a higher osmotic pressure than the cell sap, a slow shrinkage in the total volume of the cell ensues. When the lower limit of elasticity of the wall is reached the protoplasmic layer begins to recede from the wall because of continued loss of water from the cell sap. This recession often continues until the protoplasm has shrunk to a more or less rounded sack in the centre of the cell, the space between the wall and the protoplasm becoming filled with the external solution. This phenomenon is called plasmolysis. Since immersion of a cell in a solution with an osmotic pressure just barely exceeding that of the cell sap should just initiate withdrawal of the protoplasm from the cell wall, this phenomenon is the basis for one of the methods of measuring the osmotic pressure of plant cells.

Enzymes—Numerous kinds of chemical transformations are constantly occurring in physiologically active plant cells. Many of these chemical reactions can be accomplished artificially, if at all, only by subjecting the reactants to drastic conditions such as high temperatures or extreme degrees of acidity or alkalinity. Yet these reactions occur efficiently and rapidly at ordinary temperatures in a protoplasmic medium which is neither strongly acid nor strongly alkaline. This is possible because of the accelerating effect of certain organic catalysts called enzymes, which are synthetic products of the protoplasm. Two principal groups of enzymes occur in plants. Hydrolytic enzymes catalyze certain hydrolytic decomposition reactions such as digestive processes and also condensation reactions in certain synthetic processes.

Oxidizing-reducing enzymes catalyze various kinds of reactions in which energy shifts occur and participate chiefly in various steps of the process of respiration (see below, *Respiration*). A very small amount of an enzyme can catalyze the transformation of an enormous quantity of substrate. The enzyme sucrase, for example, can catalyze the hydrolysis of 1,000,000 times its own weight of sucrose to glucose and fructose, and still retain its catalytic properties apparently unimpaired. Apparently each enzyme affects only one particular type of chemical bond, when a number of compounds possess this bond in common, the same enzyme can act on all of them.

Many enzymes catalyze the same reaction in both directions. For example, lipase catalyzes the hydrolysis (digestion) of fats to glycerol and fatty acids under certain conditions, but under other conditions catalyzes the reverse condensation reaction whereby fat is synthesized from fatty acids and glycerol. Most enzymes are thermolabile and in a liquid medium are quickly destroyed at temperatures between 140° and 158° F. All of the enzymes thus far isolated in an apparently pure state have the properties of proteins.

Transpiration.—In spite of the indispensability of water for their growth and metabolism, most kinds of terrestrial plants—excepting only certain species indigenous to arid habitats—are extremely inefficient in their utilization of water. An overwhelmingly large proportion of the water absorbed from the soil is not retained within the plant or used in metabolic processes, but escapes in the process of transpiration, which is essentially a modified kind of evaporation. Although loss of water vapour, at least in limited amounts, can occur from any part of the plant exposed to the atmosphere, in general most transpiration occurs from the leaves. Foliar transpiration is of two types: (1) *stomatol* transpiration in which water vapour loss occurs through the stomates, and (2) *cuticular* transpiration in which evaporation of water takes place directly from the surface of epidermal cells through the cuticular layer which, although relatively impervious to water, does permit the passage of limited quantities. In most species stomatal transpiration accounts for 90% or more of the water vapour loss from leaves. Thanks to the investigations of Stephen Hales, in 1727, transpiration was the first major plant process studied from essentially a modern experimental viewpoint.

Physiology of Stomates.—The stomates are minute, elliptical pores which occur in the epidermis of plants, being most abundant in leaves. Every stomate is surrounded by two distinctive epidermal cells called *guard cells*. Open stomates are the principal pathways through which gaseous exchanges occur between a leaf and the atmosphere.

The principal gases which diffuse into or out of a leaf through the stomates are water vapour, carbon dioxide and oxygen. When the stomates are closed all gaseous exchanges between a leaf and its environment are greatly retarded. The size of a fully open stomate varies greatly according to species. Among the largest known stomates are those of *Zebbrina pendula* whose axial dimensions average 31×12 microns. The number of stomates may range from a few thousand per square centimetre of leaf surface in some species to over a hundred thousand per square centimetre in others. In many kinds of plants stomates occur in both the upper and lower epidermis, usually being more abundant in the lower. In numerous other species, especially trees and shrubs, they are present only in the lower epidermis. In aquatic species with floating leaves stomates occur only in the upper epidermis.

The aggregate area of the fully open stomates is only 1-3% of the total leaf area. Despite this fact, rates of stomatal transpiration are often 50%, and sometimes more, of the evaporation from a free water surface under comparable conditions. Much more important is the fact that the rate of diffusion of carbon dioxide, essential in photosynthesis (see below), into the leaf through the stomates is much greater than through an equivalent portion of the area of a fully exposed carbon dioxide absorbing surface. H. T. Brown and F. Escombe in 1900 showed that the high diffusive capacity of stomates in proportion to their area is in accord with the principles of the diffusion of gases through multiperforate septa. Diffusion rates through small openings vary

as the perimeter, not the area, hence the smaller the aperture the greater its diffusive capacity relative to its area. A gas may diffuse nearly as rapidly, therefore, through a septum pierced with a number of small apertures, whose aggregate area represents only a small proportion of the septum area, as through an open surface equal in area to the septum. Since diffusion of gases through stomates is proportional to the perimeter of the pore, diffusion rates through a partially open stomate are almost as great as when the stomate is fully open.

Increase in the turgidity of the guard cells results in opening of the stomates; decrease in their turgidity results in their closure. In general stomates are open in the daytime and closed at night, although there are many exceptions. The mechanism whereby stomates open in the light and close in its absence seems to be principally an osmotic one. Upon illumination the hydrogen ion concentration of the guard cells decreases. This favours hydrolytic action of the enzyme complex *diastase*, causing insoluble starch in the guard cells to be converted into soluble sugars. The resulting increase in the osmotic pressure of the guard cells causes an increase in their pressure deficit. Osmotic movement of water from contiguous epidermal cells, in which there is no appreciable daily variation in osmotic pressure, takes place into the guard cells. The resulting increase in the turgor of the guard cells causes the stomate to open. With the advent of darkness or even of a markedly reduced light intensity, the reverse train of processes is induced in the guard cells, leading to stomatal closure. Since light of low intensity is relatively less effective in inducing stomatal opening, stomates usually do not open as wide on cloudy as on clear days and often do not remain open for as much of the daylight period. Deficiency of water within the plant induces partial to complete closure of the stomates. During periods of drought stomates therefore remain closed much or all of the time regardless of the light intensity to which the plant is exposed. Stomatal opening does not occur in most species at temperatures approaching 32°F. Hence in cold or even cool weather stomates may remain closed even when other environmental conditions favour their opening. Nocturnal opening occurs at times in some species, but the conditions resulting in such stomatal behaviour have not been adequately investigated.

Dynamics of Stomatal Transpiration.—In most kinds of plants the cells of the mesophyll do not fit together tightly and the intercellular spaces between them are occupied by air. A labyrinth of these air-filled spaces is thus present in a leaf, bounded by the water-saturated cell walls of the mesophyll. Evaporation of water takes place from the wet cell walls into the intercellular spaces. If the stomates are closed the only effect of this evaporation is the saturation of the intercellular spaces with water vapour. When the stomates are open, however, diffusion of water vapour may occur through them into the outside atmosphere. Such diffusion always takes place unless the atmosphere has a vapour pressure equal to or greater than that within the intercellular spaces, an uncommon condition during the daylight hours of clear days. The physical processes of evaporation of water from wet mesophyll cell walls and its subsequent diffusion from the intercellular spaces through the stomates into the atmosphere are, therefore, the two main steps in stomatal transpiration.

Environmental Factors Influencing Rate of Transpiration.—Because of its usually controlling influence on the opening and closing of stomates, light is a factor of prime importance in influencing the rate of transpiration. Stomatal transpiration is largely restricted to the daylight hours; hence daytime transpiration is usually many times greater than night transpiration, which is largely or entirely cuticular. Light also has a secondary effect on transpiration through its influence on leaf temperatures, since leaves in direct sunlight usually have temperatures one to several degrees higher than that of the surrounding atmosphere.

The rate of diffusion of water vapour through open stomates depends upon the steepness of the vapour pressure gradient between the intercellular spaces and the atmosphere. Assuming open stomates, therefore, the greater the atmospheric humidity (vapour pressure) for any given vapour pressure just below the stomatal pores in the intercellular spaces, the less the rate of

transpiration. Temperature affects the rate of transpiration principally because of its differential effect upon the vapour pressures in the intercellular spaces and the atmosphere.

Although leaf temperatures do not follow atmospheric temperatures exactly, in general, increase of atmospheric temperature results in a rise of leaf temperature. Assuming a warm, clear day and an adequate soil water supply, increase in temperature results in an increase in the vapour pressure in the intercellular spaces. Such a rise in vapour pressure occurs because the vapour pressure necessary to saturate air increases with rise in temperature, and the extensive evaporating surfaces of the cell walls bounding the intercellular spaces make it possible for the intercellular spaces to be maintained in an approximately saturated condition most of the time. Rise in temperature ordinarily has little or no effect on the vapour pressure of the atmosphere. Hence the vapour pressure gradient through the stomates is steepened and the rate of outward diffusion of water vapour increases.

Transpiration rates on windy days are usually greater than on otherwise comparable but quiet days. A gentle breeze is relatively more effective in increasing the transpiration rate than winds of greater velocity. In very quiet air local regions of relatively high humidity may build up in the vicinity of transpiring leaf surfaces. Such localized zones of relatively high vapour pressure retard transpiration unless the air movement is adequate to prevent such an accumulation of water vapour molecules. The bending, twisting and fluttering of leaf blades, and the swaying of branches in a wind also contribute to increasing the transpiration rate.

Soil water conditions also influence the rate of transpiration. Whenever soil conditions are such that the rate of absorption of water is retarded, a corresponding diminution in transpiration rate soon follows.

Magnitude of Transpiration.—Transpiration rates of temperate zone plants may range up to values of about 5 g per dm² of leaf area per hour. Considerable interest also attaches to the quantities of water transpired per acre of crops, grassland or forest. An acre of corn, for example, transpires water equivalent to 15 acre inches in a growing season. Tremendous variations occur in such values from season to season, however, depending upon climatic conditions. The quantities of water vapour transpired by vegetation-covered areas of the earth's surface are often of sufficient magnitude to have important effects on meteorological conditions.

Significance of Transpiration.—Much fruitless discussion has raged over the question of whether transpiration is detrimental or beneficial to plants. The extreme viewpoints are (1) that the process is an unavoidable evil, and (2) that it is a physiological necessity. Some of the incidental effects of transpiration are advantageous to the plant, but none is indispensable for its survival or even for its normal physiological operation. Likewise, some of the incidental effects of transpiration are detrimental to the plant, but plants have transpired and survived for untold centuries.

Transpiration is a necessary consequence of the relation of water to plant structure. Terrestrial green plants cannot survive unless they obtain carbon dioxide from the atmosphere. Whatever course the evolution of green plants might follow, their structure must always remain such that carbon dioxide can reach interior cells of the leaf. The principal carbon dioxide absorbing surfaces of terrestrial vascular plants are the moist mesophyll cell walls bounding the intercellular spaces of the leaves. Ingress of carbon dioxide to these spaces occurs almost entirely through open stomates. When the stomates are open outward diffusion of water vapour is unavoidable, and this process of stomatal transpiration accounts for most of the loss of water by plants. Transpiration is, therefore, in itself an incidental phenomenon. Despite this fact it often has marked indirect effects on other physiological processes occurring in the plant, especially photosynthesis and growth, because of its influence on the internal water relations of the plant.

Guttation.—The exudation of drops of water at the tips or margins of the leaves of many species of herbaceous plants can

often be observed, especially in the early morning on a spring day. This phenomenon, called *guttation*, also occurs in some woody plants. The exuded water is not pure but contains traces of sugars and other solutes. Guttation occurs from special structures called *hydathodes*, which resemble enlarged stomates. In most species water loss by guttation is negligible compared with water loss by transpiration.

Translocation of Water.—In terrestrial plants the water absorbed from the soil moves to all living parts of the plant. The most striking examples of upward translocation of water occur in trees. The tallest known living tree is a specimen of coast redwood (*Sequoia sempervirens*) which has attained a height of 364 ft. In this tree water ascends to an elevation of nearly 400 ft., since the roots extend for at least a few feet into the soil. Many other individual trees of this species and of several others exceed 300 ft. in height. The mechanism of the ascent of sap in plants, and especially in tall trees, has long been one of the classical problems of plant physiology.

Path of Water Movement.—The upward movement of water in plants occurs in the xylem, which in the stems of trees and shrubs is identical with the wood. In the trunks and larger branches of a tree, however, sap movement is restricted to a few of the outermost annual layers of wood. For this reason hollow trees, in which most of the central core of heartwood has disintegrated, can remain alive indefinitely. The xylem of any plant constitutes a unit system which extends from just back of every root tip through all the intervening root and stem branches to the mesophyll of the leaves. In angiosperms most translocation of water occurs through *vessels*, which are elongated tubelike structures in which cross walls are of relatively infrequent occurrence. In gymnosperms movement of water occurs solely through spindle-shaped cells called *tracheids*, which may be as much as 5 mm in length. Small, often rounded, thin areas occur in the walls of vessels and tracheids which are contiguous with other vessels or cells; these *pits* are structurally of several types but all of them appear to facilitate passage of water from one xylem element to adjacent ones.

Root Pressure.—If the stem of an herbaceous plant be cut off, a slow exudation of sap often occurs from the xylem tissues at the cut surface of the stump. A similar phenomenon occurs in many woody plants, such as the maple, birch, currant and grape, especially in the spring. A vigorous grapevine often loses a quart or more of sap per day after spring pruning. The exudation of sap results from a pressure originating in the roots, called *root pressure*. There are several reasons, however, why root pressure cannot be the principal mechanism operating in the upward transport of water in plants. (1) there are many species in which this phenomenon does not occur; (2) the magnitude of measured root pressures seldom exceeds 2 atm., which could not motivate a rise of water for more than about 60 ft.; (3) known rates of flow under the influence of root pressure are inadequate to compensate for known rates of transpiration; (4) root pressures are usually present in woody plants only in the early spring, during the summer period when transpiration rates, and hence rates of sap transport, are greatest, root pressures are negligible or nonexistent. Root pressure does account for some upward movement of water in certain species of plants at some seasons, but it represents only a secondary mechanism of water transport.

Cohesion of Water and the Ascent of Sap.—Molecules of water, although ceaselessly in motion, are also strongly attracted to each other. This property of a liquid is called *cohesion*. The cohesion of water is the cornerstone of an important theory of the ascent of sap in plants (H. H. Dixon, 1914). The postulated mechanism is relatively simple. Evaporation of water from the walls of the mesophyll cells of leaves results in an increase in the pressure deficit of the mesophyll cells. Resulting intercellular movements of water cause an increase in the pressure deficit even of those mesophyll cells not directly exposed to the intercellular spaces. The increased pressure deficit of the cells abutting directly upon xylem elements in the veins of the leaf induces movement of water from the vessels or tracheids into the adjacent cells. Since, whenever transpiration is occurring at appreciable rates, water

does not enter the lower ends of the xylem conduits in the roots as rapidly as it passes out of the xylem vessels or tracheids into mesophyll cells at the upper end of the water-conductive system, the water in the xylem ducts is stretched into taut threads, i.e., passes into a state of tension. Each column of water behaves like a tiny steel wire which is stretched. Because of their saturated condition, cross walls in the xylems do not interfere with the continuity of the water. The tension is propagated along the entire length of the water columns to their terminations just back of the root tips, causing entry of water from adjacent root cells (see below, *Absorption of Water*). The tension can be sustained by the water threads because of the cohesion between the water molecules, operating in conjunction with adhesion of the boundary layers of water molecules to the walls of the xylem ducts. The existence of water under tension in vessels and tracheids has been confirmed by direct microscopic observation and in other ways. Conservative calculations indicate that a cohesion of 30 to 50 atm would be adequate to allow conduction of water to the topmost leaf of the tallest known tree. However, under conditions of internal water deficiency, tensions considerably in excess of 50 atm probably prevail in the water columns of many plants. Actual measurements of the cohesion of water yield values of 300 atm or more, which allows an ample margin above the magnitude of any tensions which ordinarily develop in water columns. This theory is the most satisfactory yet suggested to account for the translocation of water in plants.

Absorption of Water.—Soil Water Conditions.—Since soil particles never fit together tightly, there is a certain amount of space between them. This *pore space* varies from about 30% of the soil volume in sandy soils to about 50% in clay soils. The pore space may be occupied entirely by air, as in desiccated soils, or entirely by water, as in saturated soils, but is commonly occupied partly by air and partly by water. In a soil in which the water table lies relatively close to the surface, considerable quantities of water may rise into its upper layers and become available to plants. In many soils, especially in arid regions, there is no water table, and in many others, even in humid regions, the water table is continuously or intermittently too far below the soil surface to be an appreciable source of water for most plants. In such soils the only water available to plants comes through natural precipitation or artificial irrigation. If rain falls on a dry, homogeneous soil the water will become rapidly distributed to a depth which will depend on the amount of water which falls per unit area and the type of soil. After several days, further deepening of the moist blanket of soil extending down from the ground surface will virtually cease because downward capillary movement of water has become extremely slow or negligible. The boundary between the moist layer of soil and the drier zone underneath will be quite sharp. At this equilibrium condition the water content of the moist soil layer is essentially uniform throughout. The water content of a soil in this condition is termed the *field capacity*. A soil at its field capacity, although relatively moist, is also well aerated; hence soil water contents in the vicinity of the field capacity are the most favourable for the development of most kinds of plants.

A considerable proportion of the water in any soil is unavailable to plants. The *wilting percentage*, an index of unavailable soil water, is measured by allowing a plant to develop with its roots in a sample of soil enclosed within a waterproof pot until the plant passes into a state of *permanent wilting*. The water content of the soil at this point is its wilting percentage. The range of wilting percentages is from less than 5% in very sandy soils to about 20% in clay loams. The wilting percentage of a given soil is found to be about the same regardless of the kind of plant used in making the test.

The pressure deficit of the water in soils varies with the soil water content. In a saturated soil the pressure deficit is virtually zero, at the field capacity less than 1 atm., and at the wilting percentage, on the average, about 15 atm. As the water content of a soil drops below its wilting percentage, its pressure deficit increases at a rapidly accelerating rate, soon attaining a value of hundreds of atmospheres; it is for this reason that the wilting

percentage is the approximate measure of the unavailable water in soils.

Relation of Root Growth to Water Absorption.—The successively smaller branches of the root system of a plant ultimately terminate in the *root tips*, of which there may be thousands or millions on a single plant. The term *root tip* refers to the region extending back from the actual termination of the root for a distance of several to many centimetres. The terminal zone of a root tip is the dome-shaped *root cap*, just back of which are the regions of cell division and elongation (see below, *Growth*). Just back of these regions, in most species, is the root hair zone. Each root hair is a projection from an epidermal cell of which it remains an integral part. A single root tip may bear thousands of root hairs, each of which may be from a few millimetres to a centimetre or more in length. A root hair is generally a short-lived structure, but new ones are constantly developing as the root advances through the soil. Most absorption of water occurs at the root tips, especially in the root hair zone, since the older portions of roots become covered with cutinized or suberized layers which are virtually impermeable to water. Whenever the pressure deficit of root hairs and other peripheral cells of the root tip exceeds that of the soil water, movement of water into the root cells occurs. If the soil is relatively wet, in general if above the field capacity, water may move by capillarity toward the region of absorption from more remote portions of the soil, and the supply of water to root tips is largely or entirely maintained in this way. Elongation of the root tips, although slower in most species in relatively wet soils, also helps maintain their contact with untapped portions of the soil water. Many plants, much of the time, grow in soils with a water content between the field capacity and the wilting percentage. In this range of soil water contents capillary movement of water is too slow to maintain an adequate supply of water to rapidly absorbing root tips and is often nonexistent. Once most of the water on the soil particles in contact with a root tip is absorbed it cannot be replaced in significant quantities by capillary movement. In such soils it is the continued elongation of the root tips which maintains their contact with available soil water. Mature root systems of many species of plants bear millions of root tips, each of which may be pictured as slowly progressing through the soil, absorbing water from the particles with which it comes in contact. The aggregate increase in length of the root system of a rye plant averages 3.1 m. per day. Calculations by P. J. Kramer and T. S. Coile (1940) show that daily root growth of this plant apparently would permit sufficient absorption of water from soils at the field capacity to compensate for daily transpirational water loss.

Mechanism of Water Absorption.—The tension generated in the water columns of a plant as an indirect result of transpiration is propagated to the ultimate terminations of the xylem ducts in the root tips. As soon as the tension in the water columns exceeds the pressure deficit of adjacent cells in the root tip, water passes from those cells into the xylem. This engenders further cell to cell movement of water in a lateral direction across the root tip with the presumable result that a gradient of pressure deficits, constantly increasing from the epidermal cells to the root xylem, is established. As soon as the pressure deficit of the peripheral cells of the root exceeds that of the soil water, entrance of water from the soil begins.

The process just described accounts for most of the absorption of water by plants. The phenomenon of root pressure, previously described, involves an absorption mechanism which is localized in the roots. Absorption of this type occurs only when transpiration is low and the soil is relatively moist. Although xylem sap is relatively dilute, its osmotic pressure is often greater than the pressure deficit of the soil water. This leads to the establishment of a gradient of pressure deficits across the cortex and other tissues of the root tip along which water moves from the soil to the xylem. There are also some indications that other factors play a part in the mechanism of root pressure.

Environmental Factors Influencing Water Absorption.—Because of their reciprocal relation any factor which influences the rate of transpiration influences the rate of absorption. The con-

verse of this statement is also true. In addition the rate of absorption is also influenced by certain soil conditions. Within limits the greater the available soil-water supply the greater the possible rate of absorption. Extremely high soil water contents decrease absorption rates in many species because of deficient soil aeration. Low soil temperatures retard the rate of absorption of water by many species. The rate of water absorption by sunflower plants, for example, is rapidly reduced as the soil temperature drops below 55° F. Deficient aeration, characteristic of wet soils, retards water absorption in many species. In such soils the oxygen concentration is lower and the carbon dioxide concentration is higher than in the atmosphere. This retarding effect on water absorption is correlated with a retardation in the rate of root respiration. The presence of solutes in appreciable concentrations in the soil solution also retards or checks water absorption by roots. In most soils the solute concentration is too low to have any appreciable effect on water absorption, but in saline or alkaline soils the influence of this factor may be so pronounced that only a few species of plants are able to survive.

Relative Rates of Water Absorption and Transpiration.—On a clear, warm day, when transpiration rates are high, the rate of water absorption usually lags behind the rate of transpiration, largely because of the resistance of the root cells to the passage of water. As a result there is a gradual increase in the tension in the water columns and a gradual diminution in the water content of the plant, especially of the leaves, during the day. This leads to the partial loss of turgor pressure by the leaf cells, a condition called *incipient wilting*. Sometimes, especially on clear, hot summer afternoons, the decrease in water content of the leaves is sufficient to induce visible wilting. If the soil water supply is adequate, absorption of water during the night exceeds nocturnal transpiration loss, and the leaf cells gradually regain their turgor. Visible wilting caused by a temporary excess of transpiration over absorption is called *temporary wilting*, which is distinguished from *permanent wilting*, caused by a soil water deficiency. Plants automatically recover from temporary wilting during the night, but will not recover from permanent wilting unless the soil water supply is replenished.

Carbohydrate Metabolism.—The dry matter content of a plant tissue can be determined by drying it at 212° F. The dry residue remaining after the evaporation of water can be further separated into two fractions by incinerating it at about 3,100° F. The bulk of the dry matter, representing combustible organic constituents, disappears, leaving only a small mineral residue called the *ash*, which is derived from mineral salts absorbed from the soil.

An adequate explanation of the origin of the bulk of the dry matter of plants long eluded students of plant life. As a result of the investigations of Joseph Priestley, Jean Senebier, Jan Ingen-Housz, N. T. de Saussure and others in the late 18th and early 19th centuries, the gaseous exchanges between green plants and the atmosphere were first clearly envisaged. Green parts of plants, exposed to light, were found to utilize carbon dioxide and release oxygen. Nongreen parts, whether in light or dark, and green parts in the dark were found, like animals, to release carbon dioxide and consume oxygen. These gaseous exchanges are the external manifestations of the processes now known as *photosynthesis* and *respiration*, respectively. Photosynthesis occurs only in green plant organs exposed to light. Respiration occurs in all living plant tissues, green or nongreen, in light or dark. The fact that green plants usually lose oxygen and use carbon dioxide in the light does not mean that no respiration occurs in such organs in the light, but merely that the rate of photosynthesis exceeds the rate of respiration. Although de Saussure in 1804 recognized that utilization of carbon dioxide by plants contributed to their increase in dry weight, it was not until Julius von Sachs, in 1862, discovered the appearance of starch in the chloroplasts of leaf cells as an accompaniment of the consumption of carbon dioxide that the relation of the gaseous exchanges of plants to their carbohydrate metabolism began to be adequately realized.

Photosynthesis.—In the process of photosynthesis (*g.v.*),

hexose carbohydrates are synthesized from carbon dioxide and water in the chloroplasts of living plant cells, oxygen also being a product, and light the source of energy. The summary chemical equation for the process is:

Most of the carbon dioxide used diffuses into the leaf through the stomates and dissolves in wet cell walls bordering the intercellular spaces, whence it diffuses in solution to the chloroplasts. In most species less than 1% of the water absorbed is used in photosynthesis. Most of the oxygen liberated, in excess of a portion used by the green cells in respiration, passes out of solution into the intercellular spaces, whence it diffuses through the stomates into the atmosphere. Hexose sugar, most probably a mixture of glucose and fructose, is the first product of photosynthesis which can be detected in plant cells.

Plant Pigments.—In the higher plants photosynthesis occurs only in the *chloroplasts*, which are green ellipsoidal bodies about 5 microns in diameter. A single mesophyll cell may contain hundreds of chloroplasts. The green colour of chloroplasts and of leaves is due to the presence in the plastids of chlorophyll, of which there are two kinds: chlorophyll *a* ($\text{C}_{55}\text{H}_{72}\text{O}_5\text{N}_4\text{Mg}$) and chlorophyll *b* ($\text{C}_{55}\text{H}_{70}\text{O}_5\text{N}_4\text{Mg}$). Most leaves contain from two to three times as much chlorophyll *a* as chlorophyll *b*. Both chlorophylls have been extracted in pure form from the leaves of over 200 species (R. Willstätter and A. Stoll, 1928). The structural formulas of the chlorophylls were determined in 1936 by H. Fischer and S. Bretnier. In the angiosperms chlorophyll is, with rare exceptions, synthesized only in the light, in plants of all other groups it can be made either in light or dark. Among the substances which must be present in the cells for normal chlorophyll synthesis are oxygen, carbohydrates, nitrogen, magnesium, iron and water.

The role of chlorophyll seems to be a twofold one: it absorbs light of certain wave lengths, principally in the blue-violet and short red regions of the spectrum, which is used as a source of energy in photosynthesis, and it is a transitory participant in some step of the reaction, presumably acting as a catalyst. The chloroplasts also contain the yellow pigments carotene ($\text{C}_{40}\text{H}_{56}$), and the xanthophylls (mostly $\text{C}_{40}\text{H}_{58}\text{O}_2$). The leaves of any angiosperm which have developed in the dark are yellow as a result of the presence of these pigments. Carotene is the precursor of vitamin A, one molecule of carotene being split into two molecules of vitamin A by a simple hydrolysis reaction. Carotene, the xanthophylls and certain other chemically related red and yellow pigments are collectively called the carotenoids. In some plant organs, such as carrot roots, carotenoid pigments occur in the amorphous or crystalline state. The cell sap anthocyanins constitute the other principal group of plant pigments; they are responsible for most of the red, blue and purple colourations of flowers, fruits and other plant parts. Both the carotenoids and anthocyanins play a prominent part in the autumnal colouration of leaves.

Factors Influencing the Rate of Photosynthesis.—F. F. Blackman's (1905) "principle of limiting factors" has assisted materially in the interpretation of the effects of various factors on the rate of photosynthesis. This principle was stated by its author as follows: "When a process is conditioned as to its rapidity by a number of separate factors, the rate of the process is limited by the pace of the 'slowest' factor." This principle, which also holds for other physiological processes, does not admit of too rigorous an application, but in general the concept is valid that the rate of a physiological process is largely controlled by the factor present in relative minimum, the so-called "limiting factor."

Carbon dioxide constitutes only 0.03% by volume of the atmosphere, marked deviations from this value seldom occurring. In the air stratum just above the surface of rich forest or agricultural soils, however, concentrations several times the usual one sometimes occur, as a result of the upward diffusion of carbon dioxide released in the respiration of soil organisms. With increase in the carbon dioxide concentration of the atmosphere the rate of

photosynthesis increases until some other factor becomes limiting. If the natural concentration of carbon dioxide in the atmosphere were higher than 0.03%, most plants, much of the time, would photosynthesize at a more rapid rate than they do. Very high concentrations of carbon dioxide (15% or more), however, cause a retardation in photosynthesis.

Photosynthesis can occur in visible light from any source, provided its intensity is sufficiently great. The minimum light intensity at which sufficient photosynthesis occurs during an average day's length to be in excess of the consumption of carbohydrates in respiration during 24 hours—no plant can long survive at intensities less than this—differs according to species. In tree seedlings this minimum light intensity ranges from about 1% of full sunlight intensity in some shade species to about 5% in some sun species; in larger plants the minima are probably greater. For measurements made on a leaf or group of leaves, all of which are well exposed to light, the rate of photosynthesis rises with increase in light intensity until some other factor becomes limiting. At the atmospheric concentration of carbon dioxide, maximum rates of photosynthesis in single leaves are attained in many species at one-fourth to one-third of full sunlight intensity, and in some shade species at still lower values. Very high light intensities cause a retardation in photosynthesis, a phenomenon termed *solarization*.

The rate of photosynthesis for an entire tree, or for a plot of vegetation, increases consistently with increase in light up to the maximum sunlight intensity, which at noon on a clear summer's day in mid-temperate latitudes approximates 13 g cal./cm²/min. (equivalent to about 9,000 foot candles). Even in full sunlight many interior leaves of an apple tree, for example, cannot photosynthesize at their maximum capacities because they are shaded by peripheral leaves. The lower the light intensity, the greater the proportion of the leaves of which this will be true. Hence the greater the intensity of the light, the greater the average photosynthesis per unit of leaf area and the greater the total photosynthesis per tree up to the limits of sunlight intensity. All wave lengths of light are not equally effective in photosynthesis. For equal intensities of light incident on the leaf, maximum photosynthesis occurs in the orange-short red region, with a secondary maximum in the blue. Rates in the green and yellow regions are lower, but still very appreciable. The daily rate of photosynthesis is also influenced by the daily duration of the light period (photoperiod). One reason certain crops can develop to maturity during the short growing seasons of high latitudes is that more sugar can be synthesized during the long photoperiods than during the shorter photoperiods of lower latitudes.

Photosynthesis has been recorded as occurring at temperatures below 32° F in some species and, in algae of hot springs, apparently can take place at temperatures close to 160° F. Most occurrence of photosynthesis in temperate zone plants at relatively rapid rates is within the temperature range of 50°–95° F. In general, increase in temperature results in an increase in the rate of photosynthesis (an approximate doubling for each 18° F rise) up to an optimum which is not the same for all kinds of plants, but which in most temperate zone species lies within the range of 68°–86° F. Temperatures higher than the optimum, if maintained for any sustained period, cause a diminution in rate below that of the optimum.

Reduction in the water content of a plant causes a retardation in the rate of photosynthesis. This effect is not primarily a result of a deficiency of water as a raw material used in photosynthesis, but of certain indirect effects such as a reduction in the diffusive capacity of the stomates, and a decrease in the hydration of the protoplasm. In young apple trees marked diminution in the rate of photosynthesis occurs long before wilting is apparent, although even in wilted leaves some photosynthesis continues. When water is applied to the soil, wilted apple leaves recover their turgidity in a few hours, but the original rate of photosynthesis is not regained for several days (G. W. Schneider and N. F. Childers, 1941).

Conditions within the plant also affect the rate of photosynthesis. Among the internal factors which may influence photo-

synthesis are peculiarities of leaf anatomy, chlorophyll content of the cells, hydration of protoplasm, other "protoplasmic factors," and the accumulation of carbohydrates within the cells.

Mechanism of Photosynthesis—Apparently there are at least two main reactions in photosynthesis: (1) a photochemical reaction (requiring light), having a temperature coefficient of 1, and (2) a chemical reaction (also called the dark or Blackman reaction), occurring either in light or dark, having a temperature coefficient of 2 to 3. There is also evidence that at least one of the reactions in photosynthesis is enzymatic. The long popular hypothesis that formaldehyde (CH₂O) is an intermediate product in the synthesis of hexoses has been largely abandoned for want of any substantial supporting evidence.

A new approach to the problem of the mechanism of photosynthesis has been made by S. Ruben et al. (1940) who used radioactive carbon dioxide in an effort to trace the course of the photochemical reaction in the alga *Chlorella*. Most of the radioactive carbon, after the carbon dioxide had been utilized in photosynthesis, was present in -COOH groups on a large molecule. They postulate the following steps in the reaction, R being a molecule of large molecular weight:

Reaction (1) is believed to be enzymatic; reaction (2) to be photochemical. Successive cycles would proceed as follows:

Six successive cycles would lead to the formation of a six carbon atom molecular chain of the hexose type. Longer molecular chains could be built by a larger number of repetitions; it is even possible that the hexose sugars are not synthesized as units, but are formed by fragmentation of longer molecular chains.

Other important contributors to modern concepts of the mechanism of photosynthesis include D. Burk and H. Lüneveaver (1935), J. Franck and K. F. Herzfeld (1937), and H. Gaffron (1939), for further discussion see PHOTOSYNTHESIS.

Biological Significance of Photosynthesis—World-wide cessation of photosynthesis would soon result in the disappearance of all plants and animals, including man, with the negligible exception of a few species of autotrophic bacteria, because this process provides both the energy and organic substance capital of the biological world. Directly or indirectly, all plants and animals, with the minor exception just noted, obtain from green plants oxidizable carbon compounds ("food"), which alone can be used as a source of energy (see below, *Respiration*) by living organisms in growth, movement and the accomplishment of metabolic processes. All such oxidizable carbon compounds are the direct or derivative products of photosynthesis. Carbohydrates, fats and proteins all are synthesized by chains of chemical transformation from the hexose sugars produced in photosynthesis, and retain within their molecules chemical energy primarily incorporated in hexose molecules by the transformation of radiant energy from the sun. In some food chains carnivorous animals prey upon smaller or weaker carnivorous animals, which in turn prey upon smaller or weaker animals, but ultimately all such chains always lead to animals which obtain their food from green plants. Photosynthesis not only supplies the energy upon which living organisms operate, but all of the organic substance out of which bodies of plants and animals are constructed consists of the direct or derivative products of photosynthesis.

Magnitude and Efficiency of Photosynthesis—Under favourable conditions rates of photosynthesis often approximate 10–15 mg. of hexose per dm² of leaf surface per hour. Corn plants yielding 100 bu to the acre synthesize about 8,700 kg. (nearly 10 tons) of sugar in a growing season. This represents the transformation of about 33,000,000 kg. cal. of radiant energy into chemical energy. Nearly one-fourth of this is oxidized in respiration and most of the rest has been transformed into starch, cellulose and

other compounds before the plants are mature. The world production of sugar by land plants has been estimated by H. Schroeder (1919) at 4×10^{12} kg. annually which represents the transformation of 1.6×10^{13} kg. cal. of radiant energy into chemical energy.

Despite the utter dependence of the entire organic world upon photosynthesis, only a relatively small percentage of the light incident on plants is used in the process. Of the radiant energy falling on the acre of corn mentioned above only 1.6% is utilized in photosynthesis. Under certain conditions, particularly when the light intensity is low, the efficiency of the process in utilizing incident light may be as high as 5%, but rarely, if ever, is greater than that under natural conditions. From a theoretical standpoint the quantum yield of photosynthesis is of considerable significance. Investigations by W. M. Manning *et al.* (1938) and R. Emerson and C. M. Lewis (1941) indicate a maximum value of about 0.1 molecule of carbon dioxide reduced per quantum of light absorbed.

Synthesis of Other Carbohydrates.—Sucrose is universally present in plants, and is the most abundant of the plant sugars. In some plant tissues (sugar cane, sugar beet) it may constitute as much as 20% of the fresh weight, but its concentration is usually lower. Sucrose synthesis occurs by the condensation of glucose and fructose molecules, probably under the influence of the enzyme *sucrase*, according to the equation:

In rapidly photosynthesizing leaves the sucrose content usually increases during the daytime, during the night hours the concentration decreases because of its continued translocation out of the leaves to other parts of the plant. Starch is a complex, insoluble carbohydrate which is synthesized in many, but not all, species of plants. In green leaves starch synthesis occurs in the chloroplasts and apparently is initiated whenever the concentration of hexoses exceeds a certain critical value. Starch is synthesized by the condensation of large numbers of glucose molecules, probably under the influence of the enzyme complex *diasynthase*, according to the equation:

Considerable quantities of starch accumulate in green leaves during the occurrence of photosynthesis, but most of it is converted into soluble sugars and translocated out of the leaves at night. Starch is also synthesized in many other organs of the plant, as for example in potato tubers, from glucose translocated from the leaves. In the nongreen organs of plants, starch synthesis occurs in the colourless *leucoplasts*. Starch usually occurs in plant cells as microscopically visible starch grains. Cellulose, the importance of which as a cell wall constituent has already been mentioned, is also synthesized from glucose. The equation representing this reaction is exactly the same as for starch synthesis, except that starch is made from α -D-glucose molecules, cellulose from β -D-glucose molecules. Cellulose is the most abundant organic compound present on the earth. Among the other more important carbohydrates synthesized in plants are pectin, dextrins, inulin, hemicelluloses, pectic compounds, gums, mucilages, aldehydes and tannins.

Fat Metabolism.—Fats and fat-like substances, collectively called lipids, are universal constituents of plant cells. All lipids contain the elements carbon, hydrogen and oxygen, some of the more complex ones the phosphates; also contain phosphorus and nitrogen. Phosphatides and perhaps other lipids are essential ingredients of the protoplasm. Fats (called oils in the liquid state) accumulate in various organs of plants, especially in seeds and fruits, in which they constitute a reserve supply of food. Upon germination of fatty seeds the oils are digested and used in the processes of respiration and assimilation. Many vegetable oils are important items of commerce; among these are castor bean, rape, sunflower, linseed, peanut, corn, cotton, coco-nut, palm and olive oils. Lipids apparently can be synthesized in any living plant cell.

Only the synthesis of the fats is well enough understood to war-

rant discussion. There are three main steps in this process: (1) synthesis of glycerol from carbohydrates, (2) synthesis of fatty acids from carbohydrates, and (3) condensation of glycerol and fatty acid molecules. The detailed chemistry of the first two steps is not known, except that in both there is a chemical reduction with the result that both glycerol and fatty acids contain more energy than the carbohydrates from which they are made. This energy is derived from respiration. The condensation of fatty acids and glycerol to form a fat, using palmitic acid as an example, proceeds as follows under the influence of the enzyme *lipase*.

In this condensation reaction there is very little energy change, but because of the endothermic nature of the reactions by which fatty acids and glycerol are made, a fat contains about $2\frac{1}{2}$ times as much energy as an equal weight of carbohydrate.

Mineral Metabolism.—Although many other chemical elements are constituents of plants, only 14 are definitely known to be necessary in chemically detectable quantities for most kinds of plants. These are carbon, oxygen, hydrogen, nitrogen, magnesium, potassium, calcium, phosphorus, sulphur, iron, boron, manganese, zinc and copper. The first three are obtained by plants from atmospheric gases or soil water. The remainder are obtained from mineral salts which are absorbed from the soil. The last five of the elements listed above are often called trace elements because they constitute a very small proportion of the necessary mineral ration of plants. There is some evidence that the element molybdenum should be added to the list of trace elements. In agricultural soils the elements most likely to be deficient are nitrogen, phosphorus and potassium; hence most commercial fertilizers consist of mixtures of compounds of these three elements. There are many soils, however, to which one or more of the other essential elements must be added if satisfactory growth of plants is to be obtained.

Absorption of Mineral Salts.—A part of the mineral salts used by plants is absorbed from the soil solution. Another and, at least for cations, more important source of mineral elements is the clay fraction of the soil. The clay particles are largely of colloidal dimensions and bear negative charges, having associated with them certain cations in large numbers, the most common of which are hydrogen, calcium, magnesium, potassium and sodium ions. Of all these cations the hydrogen ion is held most tenaciously by the clay particles. As a result of respiration, carbon dioxide is continuously being generated in root cells. Part of this carbon dioxide reacts with water, forming carbonic acid, which in turn dissociates, forming hydrogen ions. If a root hair or root epidermal cell is in intimate contact with a clay particle, hydrogen ions from the cell exchange places with cations associated with the clay particles. This process of *cation exchange* is one of the mechanisms of absorption of ions by the roots of plants. Similar cation exchanges often occur following the addition of a fertilizer to a soil, the displaced cations passing into the soil solution.

Some of the absorption of mineral salts from the soil solution undoubtedly occurs by a simple diffusion, but a larger proportion of the absorption results from the operation of a more complex mechanism, called *osmosis*, in which many of the known facts in the cell sap of succulent species of submerged water plants such as *Valonia* (Chrys) and *Elodea* are present in a much greater concentration than in the water in which they live. A similar situation appears to exist in cells of root tips which contain various kinds of ions—especially in a freely dissolved form—substantially in concentration greater than in the medium from which they have been absorbed. Many kinds of plant cells, including those of root tips, appear to possess such a capacity of accumulating salts, *i.e.*, in causing their net movement from a medium of their lesser concentration to one of their greater concentration, which is directly opposite to the direction in which they would move if simple diffusion were the mechanism of movement. Furthermore, such cells possess the capacity of retaining accumulated salts in the cell sap at a higher concentration than in the surrounding medium. In this process, unlike the

cation exchange process, both the anions and cations of a salt usually pass into a cell in electrostatically equivalent quantities. The accumulation of salts and their retention in the cell in a higher concentration than in the surrounding medium is correlated with an adequate rate of aerobic respiration within the cells. Presumably energy released in respiration is utilized in the process. Absorption of water and absorption of mineral salts both occur principally through the root tips although the mechanisms of the two processes are entirely different. Continued growth of the root tips through the soil is an important factor in the absorption of mineral salts, particularly in soils at water contents below the field capacity.

Roles of Mineral Elements in Plants.—Plants absorb many kinds of ions which are not necessary for their development, and commonly absorb necessary ions in quantities greater than are utilized in the metabolism of the plant. Absorption of ions, therefore, is not necessarily followed by their utilization. Generally speaking, however, most of the ions of essential elements which are absorbed are utilized in one manner or another in metabolic processes, or else have important influences upon physiological conditions within the plant. Many of the mineral elements are important constituents of protoplasm, cell walls, or accumulated foods within the plant. The osmotic pressure, hydrogen ion concentration, buffer action, and permeability of plant cells are all influenced by mineral salts or their constituent ions. Some mineral elements act as catalysts in the plant. Others have, in certain concentrations, toxic effects which often may be offset by the presence of other ions, a phenomenon known as *antagonism*. Examples of specific roles of most of the essential mineral elements are given at other places in this article.

Absence or deficiency of any of the essential mineral elements sooner or later becomes apparent in the plant as aberrations in growth or pigmentation. Characteristic visible symptoms of the deficiency of each of the essential elements have been recognized for a number of kinds of plants. Ability to identify such symptoms is of value in diagnosing developmental disorders in plants under natural or cultural conditions.

Hydroponics.—J. von Sachs in 1860 and W. Knop in 1865 were the first to use the method of water culture (solution culture) for studying the mineral salt relations of plants. In this method the plants are grown with their roots immersed in dilute solutions containing dissolved salts (so-called nutrient solutions). An alternative procedure is to grow plants with their roots in pure quartz sand or gravel which is kept moist with the solutions. By comparing the development of plants in solutions containing different kinds and proportions of ions, or the growth reactions of plants in a solution markedly deficient in one of the necessary elements with its growth in a complete solution (one containing all necessary elements) many important facts concerning the mineral nutrition and metabolism of plants have been discovered.

Solution and sand cultures have been used by plant physiologists as a laboratory technique for many years, but it was not until about 1936 that the extension of these methods to the commercial culture of plants in large tanks was attempted, a procedure for which the name hydroponics has been proposed. In one such method plants are supported in a matrix of peat, excelsior or some similar material on a wire screen with their roots projecting into a tank of solution below. Provision for adequate aeration of the solution is necessary if suitable development of the plants is to be insured. In another method the plants are rooted in a medium of coarse sand, gravel, or haydite (fused shale) contained in large shallow tanks into which the solution is automatically pumped at intervals from a reservoir, to which it drains back after each cycle of pumping. Considerable success in the culture of certain greenhouse crops by these methods has been reported by commercial growers. The principal salts used in preparing solutions suitable for use in "soilless" plant culture are potassium dihydrogen phosphate, calcium nitrate, potassium nitrate, magnesium sulphate, ammonium sulphate and iron tartrate. Technical details of such culture methods are given in special handbooks (W. I. Turner and V. M. Henry, 1939; C. Ellis and M. W. Swaney, 1938; A. Laurie, 1940).

Nitrogen Metabolism.—Proteins, as already noted, are, next to water, the most abundant constituent of protoplasm. Proteins also accumulate in certain plant organs in considerable quantities, especially in the seeds of legumes. Upon germination of such seeds the proteins present are digested and utilized in the processes of assimilation and respiration. All molecules of plant proteins contain the elements carbon, hydrogen, oxygen and nitrogen. Sulphur also appears always to be a constituent, although present in relatively small quantities. Phosphorus is also a component of certain plant proteins.

In spite of the fact that nitrogen gas constitutes about 79% of the atmosphere, green plants are not able to utilize nitrogen from this source. Leguminous plants, an apparent exception to this statement, obtain atmospheric nitrogen indirectly through metabolic activities of symbiotic bacteria living in nodules on their roots. The well-known influence of legumes in enhancing the nitrogen content of soils is dependent upon the action of these bacteria. Most green plants obtain their nitrogen as a constituent of the nitrates or ammonium compounds which they absorb from the soil.

Protein molecules are synthesized by the condensation of large numbers of molecules of *amino acids*. More than 15 different amino acids occur in plants. The simplest amino acid is glycine: $\text{CH}_2 \cdot \text{COOH}$. Most amino acids have a more complex molecu-

NH_2 lar structure, at least one plant amino acid (cystine) also contains sulphur. Amino acids are apparently synthesized from organic acids derived from carbohydrates and from the nitrogen absorbed as nitrates or ammonium compounds. The sulphur present in cystine and possibly other amino acids is absorbed by the plant as sulphates. In some species of plants (apple, asparagus, certain grasses) synthesis of amino acids occurs principally in the roots, while in others (peas, soybean, tomato) it occurs principally in the aerial parts. The principal regions of protein synthesis do not necessarily correspond with the principal regions of amino acid synthesis. Amino acids may be made in one part of a plant, translocated to other parts, and used there in protein synthesis. Condensation of amino acids resulting in the formation of proteins occurs chiefly in the meristems and in certain storage tissues, especially in seeds. The condensation of amino acid molecules occurs mainly by their union through the *peptide linkage*. Using two glycine molecules for illustration, this process occurs as follows:

By the linking together of at least several hundred amino acid residues in this fashion the long, complex molecular chains characteristic of proteins are built up. A number of different kinds of amino acids enter into the constitution of each protein molecule, these are not arranged in a haphazard manner, but according to definite linear sequences, which are different and characteristic in each kind of protein. Many of the proteins found in the nuclei of plant cells contain phosphorus. Such proteins are complex compounds formed by the combination of proteins and the phosphorus-containing nucleic acids. Among the compounds important in the protein metabolism of plants are aspartic acid and glutamic acid, respectively, both of which are important plant amino acids. Organic nitrogen is often translocated from one part of the plant to another as asparagine, and this compound also commonly occurs as a temporary storage food. Alkaloids, complex nitrogen-containing compounds, very different in chemical constitution from the proteins, occur in some species of plants. Examples are nicotine, quinine, strychnine and morphine. These compounds are apparently only incidental products of plant metabolism; many of them, however, are important in therapeutics.

Translocation of Solutes.—Downward Translocation of Or-

Translocation of Mineral Salts.—The mineral salts absorbed from the soil by the roots are mostly translocated in an upward direction in plants, a large proportion of them ultimately reaching the leaves. Considerable controversy has floundered over whether upward movement of the mineral salts occurs principally in the xylem or principally in the phloem, but the preponderance of the evidence at present indicates that the xylem is the chief tissue through which mineral salt transport occurs (P. R. Stout and D. R. Hoagland, 1939). The dissolved mineral salts, generally in very low concentration, are passively carried in an upward direction through the ascending streamlets of water in the xylem ducts. The periodicity of upward movement of certain mineral salts, such as the alkalies, is probably a function of the periodicity of the transpiration stream, but evidence is not available that mineral salts are translocated in the phloem streamlets. The translocation of certain mineral elements is not a general phenomenon. For example, as constituents of certain compounds one of the alkalies and the silicic acid, translocate to other organs, or in other leaves is a frequent occurrence in plants. The proportion of the dissolved leaves or other parts a considerable proportion of the dissolved phosphorus is absorbed, and it is interesting to note that it is translocated back into the stems. Such movements of minerals out of leaves occur through the phloem. There are also indications of a periodic daily "circulation" of at least certain of the minerals in the plant. Mobile phosphorus compounds, for example,

—**Influence of Respiration Rate on Net Rate of Photosynthesis.**—The average quantity of hexose produced in photosynthesis by a corn plant during its life history is about 9 g per photoperiod, while the average amount of hexose consumed in respiration dur-

ing its life history by the entire plant is about 2 g per 24-hour day. The difference between these two quantities is the *net daily rate of photosynthesis* and represents the amount of hexose which can be utilized by the plant in assimilation or which may accumulate as unused food. The average net daily rate of photosynthesis is an important consideration in evaluating the survival and development of plants, as, in general, the greater this quantity the larger the plant can grow and the more food that can accumulate. Temperature has an important effect on net daily photosynthesis because of its differential influence on the rates of respiration and photosynthesis.

In many and perhaps all species the temperature optimum for respiration is higher than the optimum for photosynthesis. In the potato, for example, the temperature optimum for photosynthesis, under otherwise favourable conditions, is about 68° F, while the optimum for respiration, at least of the leaves, is about 95° F. Hence, the higher the temperature above the photosynthetic optimum, the greater the proportion of the photosynthate which is consumed in respiration in one part of the plant or another, and the smaller the net daily photosynthesis. At relatively high temperatures, therefore, there is relatively less food which can be used in the construction of new tissues and which can accumulate in the tubers or other organs. This is the explanation of the well-known fact that the potato is a cool climate crop. The same principle also applies to other species, although the temperature which results in maximum daily rates of net photosynthesis varies with other environmental factors and with the species, being in general higher in species indigenous to warm climates than to those indigenous to cool climates. Analysis of this effect of temperature on plants is complicated by the fact that plants in nature are exposed to a daily cycle of temperature variations, the general pattern of which varies from season to season and habitat to habitat.

Fermentation.—When a dilute sugar solution becomes inoculated with yeast cells the process of alcoholic fermentation ensues

This reaction is catalyzed by the enzyme complex *zymase*, contained in the yeast cells. Although an oxidation reaction, it can proceed in the complete absence of atmospheric oxygen, i.e., it is *anaerobic*. Even when oxygen is present yeast cells carry on relatively little aerobic respiration, still obtaining most of their energy from the relatively much less efficient process of fermentation. A process identical with, or at least closely similar to alcoholic fermentation occurs in the tissues of green plants under certain conditions. If kept in an atmosphere devoid of oxygen many plant tissues continue to release carbon dioxide while ethyl alcohol or other end products accumulate in them. In some plant organs anaerobic respiration occurs even in the presence of oxygen. This is true in the earlier stages of germination of some kinds of seeds and grains (pea, oat, sunflower) because of virtual impermeability of the coats to oxygen. The skin of the grape and some other fruits is also highly impermeable to oxygen, and considerable anaerobic respiration doubtless occurs in such organs. Many tissues of higher plants are soon injured if anaerobiosis continues very long. If corn seedlings, for example, are deprived of oxygen signs of injury will appear in them within a day. The injurious effect of anaerobic respiration on many plant tissues is probably in part a result of the low energy output of this process, and in part of the accumulation of alcohol or other toxic products within the tissues. Some senescent tissues, such as apple and pear fruits, on the other hand, continue to lose carbon dioxide and remain uninjured for months when stored in pure nitrogen or hydrogen.

Mechanism of Respiration.—The process of respiration comprises a complex series of reactions; the details of which cannot be given in a brief discussion. The earlier steps in respiration and fermentation appear to be identical. Apparently hexoses, in an activated form, are first converted into trioses (3-carbon atom sugars) after a temporary combination with phosphates, which play an important rôle in the process. In the absence of oxygen various other intermediate products are formed, including gly-

ceric acid, pyruvic acid and acetaldehyde, but the ultimate products of the reaction chain are alcohol and carbon dioxide. Most steps in this series of reactions appear to be catalyzed by enzymes of the *zymase* complex. In the presence of oxygen, fermentation is largely or entirely inhibited and trioses or perhaps other intermediate products of fermentation undergo complete oxidation to carbon dioxide and water, probably largely under the influence of oxidases and dehydrogenases. The highly reactive compounds formed as intermediate products of fermentation or respiration are not all oxidized to the usual end products of these reactions, but a considerable proportion of them are used in fundamental anabolic processes within the cell.

Growth.—The co-ordinated development of plant organs and tissues is just as clearly a type of physiological activity as relatively simpler processes such as photosynthesis and respiration. The tissues and their constituent cells resulting from the complex of physiological processes referred to as growth in turn become factors influencing subsequently occurring physiological processes in those tissues. Growth of plants occurs primarily in meristems, which are tissues in which the cells retain a capacity for cell division. The principal meristems of a vascular plant are the apical stem meristems, the apical root meristems and the cambium (not present in ferns or monocots). An embryo plant has only one apical stem meristem, but with the development of the branching stem system there comes to be such a meristem at every growing stem tip and in every bud. Hence there may be thousands of apical stem meristems on any plant with an extensive system of branching. Likewise there is only one apical root meristem on an embryo plant, but with the branching of the root system the number of such meristems on a single plant may exceed many thousands or even millions, since one is present at every root tip.

Growth of any meristem proceeds by successive microscopically visible stages of *cell division*, *cell enlargement* and *cell maturation*, which are the three principal morphological phases of growth. The terms for the first two stages of growth are self-explanatory. Cell maturation refers to the final stage in growth during which most of the distinctive structural and chemical differences in the walls of the various kinds of cells develop. It is also the stage in which the protoplasm disappears from many kinds of cells as, for example, most cells of the xylem. An actively growing meristem is a centre of intense assimilatory activity, *assimilation* being the term used to refer to the construction of new cell walls and protoplasm from foods. Protoplasmic proteins are made by the condensation of amino acids, principally during the cell division stage of growth. Cellulose, pectic compounds and other cell wall constituents are synthesized by the condensation of soluble carbohydrates, principally during the cell division and cell enlargement phases of growth. Water is incorporated into the cells in considerable quantities during both cell division and cell enlargement, some entering into the hydration of newly formed cell walls and protoplasm, and larger quantities entering into the expanding vacuoles, particularly during cell enlargement. Translocation of water and soluble foods is, therefore, constantly in progress toward growing meristems. Translocation of essential minerals, as soluble compounds of one kind or another, is also continually occurring toward growing meristems. Certain growth substances must also be present if growth is to occur. Regions of cell division and cell enlargement are also centres of intense respiratory activity, considerable quantities of carbohydrates being oxidized in such cells, much of the resulting energy being utilized in various dynamic and metabolic processes which are integral phases of growth. Respiration rates during the maturation phase are distinctly lower than during the two preceding stages of the growth process.

Growth from primary meristems is called *primary growth* and results in all increase in the length of stems and roots, in the development of their branching system, in the development of the primary tissues of such organs, and in the production of all lateral appendages, such as leaves, floral parts and root hairs. Primary growth of plants is not a continuous but a periodic phenomenon, periods of growth having in general a correlation

with favourable seasons, but varying greatly from one species of plant to another. The periodicity of root growth in a given species is usually different from the periodicity of stem growth, often beginning earlier in the season than stem growth and continuing after the latter has ceased. Most of the secondary growth of plants is initiated in the cambium, which is a uniseriate layer of cells located between the xylem and phloem. In most plants in which it occurs the cambium is present as an almost continuous layer of cells extending from just back of every root tip to just below every stem apex. As a result of secondary growth in a lateral direction xylem cells (secondary xylem) are formed on the inner side of the cambium and phloem cells (secondary phloem) on its outer side (the first layers of these two tissues, primary xylem and primary phloem develop during primary growth). In woody perennials secondary tissues may develop from the cambium for hundreds of years, cambial activity being resumed periodically with the advent of each growing season. The diameter of the woody cylinder is thus increased from growing season to growing season, and commonly each season's layer of xylem (wood) can be distinguished in cross sections of the wood as a definite annual ring.

FIG. 11.—EFFECT OF DETIPPING OAT COLEOPTILE ON ITS SUBSEQUENT ELONGATION. (A) INTACT COLEOPTILE. (B) TIP REMOVED AND REPLACED. (C) TIP REMOVED. DIFFERENCES IN ELONGATION OF COLEOPTILES SHOWN AT RIGHT.

side branches and are called lateral buds, usually being covered with bud scales in woody species. The branching stem system of the plant is a result of the development of the lateral buds into side branches. Branch roots, on the other hand, develop from meristems which originate in interior pericycle tissue. In many woody plants scale-enclosed terminal buds form annually at the tip of each stem axis. In the woody plants of temperate regions resumption of growth from the terminal buds and from some of the lateral buds occurs each spring, continuing for a few weeks to several months, depending upon the species of plant and the environmental conditions. In most species of plants some of the apical stem meristems sooner or later become differentiated into flower primordia from which develop flowers and, ultimately, fruits and seeds.

Hormones.—Hormones are substances synthesized within an organism which, in very minute concentrations, exert profound effects on its metabolism or growth, often after translocation to parts or organs remote from their centre of production. Although the existence of such substances in plants had been suspected for many years, the first convincingly clear demonstration of the presence of growth hormones (growth substances) in plants was not made until the in-

vestigations of F. W. Went in 1928.

The auxins have been the most thoroughly studied of the plant hormones. Their action has been investigated mostly in the coleoptile of the oat, which is the first part of the plant that emerges above the ground in germination. This is a cylindrical structure several centimetres in height, which encloses the first leaf. If the tip of an oat coleoptile is removed, elongation of the stump is greatly retarded as compared with an intact coleoptile. If the cut-off tip is replaced on the coleoptile, nearly the original rate of elongation may be regained (fig. 11). Furthermore, if the cut-off tip is placed with its cut surface in contact with a small block of agar gel for about an hour, and the agar block then be affixed on the cut surface of a detipped coleoptile, that coleoptile will elongate at nearly its usual rate. No such effect will be obtained if a block of pure agar is used (fig. 12). Cell divisions cease very early in the development of a coleoptile and the cell elongation which results in its increase in length is restricted to the basal portion. The facts just cited indicate that the tip exerts a controlling influence on the elongation of basal cells of the coleoptile and, furthermore, as shown by the agar block experiment, this controlling influence must be ascribed to some diffusible substance or substances which move from the tip toward the base through the coleoptile. These substances are called auxins. If an agar block containing auxins from one source or another is affixed one-sidedly on a detipped coleoptile, cell elongation is found to be more rapid on a side of the coleoptile below the portion of the tip on which the block is located, resulting in curvature of the coleoptile (fig. 13). Translocation of the auxin is almost strictly longitudinal, the elongating cells on the side of the coleoptile below the block receiving more than cells on the opposite side, with a corresponding differential effect on growth. Within limits of 0 to 20 degrees, curvature resulting from the eccentric attachment of agar blocks containing auxin to detipped coleoptiles is proportional to the concentration of auxin in the blocks. This proportionality between auxin concentration and coleoptile curvature has made it possible to use the bending of oat coleoptiles as the basis for a quantitative and extremely sensitive biological test for auxins. Auxins are essential for the occurrence of cell elongation in all plant cells. In their absence elongation ceases; in their presence elongation occurs if no other factors are limiting, and within limits, elongation is proportional to auxin concentration. Relatively high concentrations of auxins inhibit cell elongation, and the concentration most favourable for elongation is different in different tissues, being, for example, much higher in stems and coleoptiles than in roots. Three auxins have been isolated from plant tissues in a chemically pure state: auxin *a* ($C_{15}H_{15}O_3$), auxin *b* ($C_{15}H_{15}O_4$), and heteroauxin ($C_{10}H_9O_2N$). A number of synthetic compounds have been discovered which are not known to occur in plants, but which have many of the same effects as auxins.

Certain auxins influence root formation in plants. More roots form on cuttings of many kinds of plants if they are first immersed in a dilute solution of one of the auxins before placing in a rooting medium than if not so treated. Some of the synthetic auxins, notably indole-butyric acid and α -naphthaleneacetic acid, are especially effective in inducing root formation. The hormone may be applied in solution, in a paste, as a vapour, or in a powder. Comprehensive data on the use of hormones for this purpose are given by J. W. Mitchell and R. R. Rice (1942).

The detachment of leaves, fruits and certain other parts of plants from stems usually occurs by the process of abscission.

FIG. 13.—STEPS IN TESTING FOR AUXINS QUANTITATIVELY BY DEGREE OF BENDING OF AN OAT COLEOPTILE. (A) INTACT COLEOPTILE. (B) TIP OF COLEOPTILE REMOVED. (C) PRIMARY LEAF PULLED LOOSE AND ITS TIP CUT OFF. The first step in the abscission of leaves or fruits is the formation of an *absciss layer* across the base of the petiole of the leaf or the peduncle of the fruit. The absciss layer is a transverse zone consisting of several layers of parenchymatous cells. It may form weeks or months before detachment of the leaf or fruit occurs. Abscission proper, which in the leaves of deciduous trees of temperate regions occurs principally in the autumn, takes place as a result of dissolution of the middle lamella between layers of cells in the absciss layer. Artificial introduction of auxin into leaf petioles at a time when they would ordinarily abscise within a short period materially delays the time of abscission. A practical application of this discovery is to spray apples with a solution of α -naphthalenacetic acid shortly before harvest in the fall. Application of such a spray delays abscission of the fruits and makes it more likely that they can be picked before they fall to the ground and deteriorate in quality.

Usually fruit development ensues only after pollination and subsequent fertilization have occurred. If, however, pollination is prevented and any one of several of the auxins is introduced into the pistil by a suitable technique, development of the fruit will occur (F. G. Gustafson, 1936). Such *parthenocarpic* fruits are seedless. A practical application of this discovery has been in the treatment of greenhouse tomato flowers with indole-butyric acid during the winter season of low pollen viability. Larger crops can often be obtained under such conditions by supplementing the normal pollination process with growth substance treatment (F. S. Howlett, 1942). Several other physiological effects of the auxins are described below.

The auxins are not the only growth substances which occur in plants. J. English *et al.* (1939) have isolated traumatic acid from plant tissues, a compound which induces renewed growth activity in parenchymatous cells. Thiamin, known as a necessary vitamin in animal metabolism, acts as a hormone in plants. It is synthesized principally in leaves, whence it is translocated to other parts of the plant (J. Bonner, 1942). Thiamin is necessary for root growth and probably in other ways. There are also indications that other vitamins of the B complex may be necessary for root development. The extravagant claims sometimes made for thiamin (vitamin B₁) as a promoter of overall plant growth have not been substantiated by critical experiments (D. I. Arnon 1940, C. L. Hamner 1940). Coco-nut milk has been found by J. van Overbeek *et al.* (1942) to contain a growth substance which is necessary for the development of plant embryos. This substance induces repeated cell divisions in the embryo. Very minute embryos of *Datura* developed into fully formed embryos when placed in a synthetic medium containing coco-nut milk, but failed to develop when placed in the same medium without coco-nut milk. Indications of the existence of certain growth substances which specifically promote leaf growth have also been obtained (D. M. Bonner and J. Bonner, 1940).

Factors Influencing Growth.—The process of growth is so complex that it is impossible to characterize it by any single index. Quantitative measurements may readily be made of such aspects as increase in lengths of stems or roots, increase in diameter of a stem, increase in volume of a fruit, or increase in dry or fresh weight of a plant organ. However, qualitative differences in growth are often of greater significance than quantitative differences. The relative development of vegetative and reproductive growth, for example, or whether the vegetative growth is soft and succulent or hard and woody are often of greater import from a physiological or practical standpoint than the absolute development of any plant organ or organs, measured as length or weight. Such developmental differences must be characterized largely in descriptive terms rather than in quantitative measurements.

The growth and reactions of a plant are the result of the coordinated interplay of its hereditary factors and the environmental conditions to which it is exposed upon its internal physiological processes. Genetic factors have as much influence on the development of a plant as environmental factors, but a detailed consideration of their effects cannot come within the scope of this article. The environment of plants is too complex to be sub-

jected to any completely logical analysis, but the following are the principal factors of the physical environment which have effects upon the rate and type of growth of plants. Radiant energy (intensity, quality, duration), temperature of air and soil, atmospheric humidity, soil water supply, soil aeration, supply of available minerals in the soil, concentration of gases in the atmosphere, gravity and atmospheric pressure. Since an individual factor can vary in more than one way, since various interrelations exist among the different factors, and since each factor can induce various chains of reactions in a plant, interpretation of the effects of an individual environmental factor on the growth of plants is usually a complex problem. The principle of limiting factors can be applied in the approximate analysis of many growth phenomena. In this epitomized discussion the influence of only a few of these environmental conditions can be considered in detail.

Photoperiodism.—The reaction of plants to the length of the daily period of illumination is called photoperiodism. The daily length of the photoperiod varies from latitude to latitude and from season to season in the same latitude. In the tropics, seasonal variations in the photoperiod are small, day lengths approximating 12 hours the year round. In mid-temperate regions, photoperiods vary in length from 8 or 9 hours in December to 15 or 16 hours in June. In arctic regions the photoperiod drops to a zero value in December, and is of 24 hours' duration in June. Although the length of the photoperiod has certain effects on the vegetative development of plants, its most noteworthy influence is upon reproductive development. W. W. Garner and H. A. Allard, in 1920, showed that plants fall into three classes. (1) "short-day" plants which flower more or less readily in a range of day lengths shorter than a certain critical photoperiod, flowering being inhibited or at least greatly retarded at all longer photoperiods, (2) "long-day" plants, which flower more or less readily only in a range of day lengths longer than a certain critical one, flowering being inhibited or at least greatly retarded in shorter photoperiods, and (3) "indeterminate" species which exhibit no critical photoperiod and which develop both vegetatively and reproductively over a wide range of day lengths. The "critical photoperiod" for many species is between 12 and 14 hours. The exact intensity of light is often not very significant in photoperiodism, supplementing a relatively short natural photoperiod with additional hours of much weaker artificial light often has essentially the same effect on reproduction as a long natural photoperiod. Examples of short-day plants include: cocklebur, salvia, aster, dahlia, poinsettia, chrysanthemum and violet; of long-day plants: spinach, radish, dill, lettuce, grains, timothy and hibiscus, of indeterminate plants: sunflower, tomato, cotton, chickweed, dandelion and buckwheat. Spring-flowering plants are mostly of the short-day type, the flower primordia having been formed during the shortening days of the preceding late summer and autumn. Autumn-flowering plants fall into a similar category, except that the flower primordia are initiated during the current instead of the preceding season. Summer-flowering plants are mostly of the long-day type. Indeterminate species may flower at any season during which other environmental conditions are favourable.

The daily length of the photoperiod is one of the important factors influencing the ecological distribution of crop plants and plants in nature. Species of the pronounced long-day type cannot survive under natural conditions in the tropics, and similarly, species of the pronounced short-day type can not survive under natural conditions in more northern latitudes, excepting only those which are maintained by vegetative propagation. Biloxi soybeans (a short-day variety), for example, fruit readily in the gulf states of the United States, but not in the latitude of Washington, D.C. In the latter region days short enough to induce flowering come so late in the season that fruits are killed by frost before they can ripen. Indeterminate species can develop over such a wide range of day lengths that their ecological distribution is controlled by factors other than length of the photoperiod.

The fundamental difference between short-day plants and long-day or indeterminate plants seems to be that the former require an alternating cycle of light and dark periods if flowers are to de-

velop, while the latter do not. In the Biloxi soybean, a dark period at least 11 hours long must alternate with photoperiods which may be from 4 to 18, but optimally from 10 to 12 hours in length if flower primordia or flowers are to form (K. C. Hamner, 1940). Most and perhaps all long-day and indeterminate species, on the other hand, can flower even under continuous illumination, although the plants do not necessarily reach their best development under such conditions. The principal difference between the plants of these two groups appears to be that the indeterminate species can flower under shorter photoperiods than the long-day species.

When the leaves of short-day Biloxi soybean are exposed to short photoperiods while apical growing regions are kept under long photoperiods or in total darkness, initiation of flower primordia occurs. If the growing tip of the plant is exposed to short photoperiods and the leaves to long photoperiods, no such initiation occurs (H. A. Borthwick and M. W. Parker, 1938). Similar results have been obtained in experiments with short-day cocklebur plants (K. C. Hamner and J. Bonner, 1938). Likewise, if only the leaves of a long-day dill plant are exposed to photoperiods of suitable length, flower initiation occurs (Hamner and A. W. Naylor, 1939). These facts indicate that the leaves are the loci of the reactions which lead to the flowering of plants, and that the effects of processes which occur in the leaves are transmitted to the apical meristems, causing them to differentiate into flower primordia. Under the influence of photoperiods of the proper duration it seems likely that a substance (or substances) is made in the leaves, whence it is translocated to the terminal meristems, inducing flower formation. The name "florigen" has been proposed for this postulated flower-inducing hormone.

It is not necessary for plants to be exposed continuously to photoperiods of the proper length for the initiation of flowers to occur. Biloxi soybeans, which have been growing under long days will initiate flower primordia after exposure to only two short-day cycles and a return to long days. Similarly in the cocklebur, one short-day cycle, and in the morning glory, four short-day cycles, are adequate to induce formation of flower primordia. Likewise, four long-day cycles are sufficient to initiate flowering in long-day dill plants which are kept under short days before and after the exposure to long days. However, more primordia are usually initiated if plants are exposed to a longer series of

some species, relatively high temperatures favour flower initiation in other species, and flowers are initiated in still other species over a wide range of temperatures (H. C. Thompson, 1939). Celery plants which have been exposed to a temperature range of 40°-50° F or 50°-60° F for 10-15 days will develop flowers, fruits and seeds if subsequently grown at 60°-70° F, a range of temperatures too high for the initiation of flowering. On the other hand, lettuce plants (White Boston) develop flowers, fruits and seeds without forming heads if grown at 70°-80° F. Similar plants grown at 60°-70° F first form heads and subsequently go to seed. Other species for which exposure to a relatively low temperature seems essential to induction of flowering include rutabaga, onion, cosmos and stock; other species for which exposure to a relatively high temperature seems essential to induction of flowering include pepper, phlox and cleome.

Growth Correlations.—The influence of one part of a plant upon the development of another part of the same plant is called a growth correlation. The harmonious development of the plant body as a whole is controlled by correlative influences operating reciprocally from organ to organ, tissue to tissue, and cell to cell. Innumerable examples of growth correlations can be cited. A familiar one is the phenomenon of *apical dominance*. As long as the terminal bud on a woody stem remains intact or continues to grow, development of lateral buds, at least on the current season's shoots, fails to occur. If the terminal bud is injured or destroyed, however, development of the lateral buds usually ensues. Obviously the terminal bud has some sort of an influence on the lateral buds which prevents their development. Apical dominance also occurs in the growing shoots of herbaceous plants. When the terminal bud is removed from a broad bean and replaced with a block of agar gel containing auxin *b* or heteroauxin, inhibition of lateral bud development continues just as if the terminal bud remains intact. If the terminal bud is replaced with a block of plain agar, however, lateral buds begin to develop immediately. It is obvious that auxin plays a role in apical dominance, but the exact mechanism of their action has not been worked out. Many, but not all correlative influences of one plant organ on another result from the action of growth substances. One part of a plant often has an influence on the relative quantities of certain foods, of mineral compounds, or of water which reach other parts of the plant, and correlative influences on growth often result from such effects. For example, if the nitrate supply is low, the root system of a plant is large in proportion to its top. Under such conditions absorbed nitrates are largely used in the synthesis of amino acids in the roots and these amino acids are used in protein synthesis accompanying root growth. Only small quantities of nitrogenous compounds escape utilization in the roots and are translocated to the tops. Hence the growth of the tops is checked by a deficiency of nitrates or amino acids, even though they may contain an abundance of carbohydrates, some of which are translocated downwards and used in amino acid synthesis and other processes in the roots. If the supply of nitrates is more abundant, however, more nitrogenous compounds are translocated to the tops, where most of them are used in the synthesis of protoplasmic proteins. The resulting enhanced vegetative growth of the tops results in a greater proportionate development of the aerial portions of the plant as compared with the roots than occurs when the nitrogen supply is deficient.

Dormancy.—Many kinds of seeds, apparently mature, fail to sprout even when brought under environmental conditions favourable for germination. This state of internally inhibited growth of seeds or other plant organs is called dormancy. The following are the main causes of dormancy in seeds: (1) seed coats impermeable to water; (2) seed coats mechanically so strong that they cannot be ruptured by swelling of the embryo; (3) seed coats impermeable to oxygen; (4) seed coats containing a specific chemical inhibitor of germination; (5) embryos in a rudimentary state at the time seeds are shed; (6) embryos fully formed at seed maturity but in such a physiological condition that they will not develop further until they have passed through a period of "after-ripening." More than one of these conditions is present in some kinds of seeds. Methods of "breaking" the dormancy,

Struckmeyer (1939), night temperatures have a modifying effect on the photoperiodic reactions of many plants. A number of practical applications of the principles of photoperiodism have been made. By artificially increasing or decreasing the length of the photoperiod, for example, many floricultural plants can be brought into bloom sooner than if exposed to natural photoperiods.

Temperature Effects on Growth.—Within limits a rise in temperature favours increased rates of elongation or enlargement of plant organs. The range of temperatures within which this occurs is usually higher in tropical than in temperate zone species, and higher in plants of the latter group than in subarctic species. In temperate zone species, the temperature range over which such an effect occurs approximates 40°-95° F. With further rise in temperature above the optimum, elongation or enlargement rates decrease, falling to zero at about 105°-115° F. The temperature most favourable for one stage of development of a plant is often not the most favourable for another stage.

Relatively low temperatures favour initiation of flowers in

or at least shortening the period of dormancy, have been devised for a number of kinds of seeds and are of considerable practical utility. The method used with a given kind of seed depends upon the cause of dormancy in that particular seed.

The phenomenon of dormancy is also exhibited by buds. The buds on stems of woody temperate zone species ordinarily do not develop during the summer in which they are formed, even under favourable environmental conditions. This condition of dormancy is maintained in most such species until the following autumn or winter. Exposing stems to vapours of ether, ethylene dichloride, or ethylene dichloride is an effective method of breaking bud dormancy in many woody species. The buds of many kinds of tubers, rhizomes, corns and bulbs likewise may remain dormant for a considerable period. Freshly harvested potato tubers, for example, ordinarily do not sprout at once because of bud dormancy. The duration of dormancy in potato tubers can be greatly curtailed by treatment with certain chemicals.

Verzalization—This term refers to a low temperature treatment given seeds before sowing which results in shortening the time until flowering of plants that develop from them. Less commonly, it is also applied to treatment of seeds at relatively high temperatures, or to temperature treatments of plant organs other than seeds (H. H. McKinney, 1940). Although seeds of a number of kinds of plants can be verzalized, this technique is employed principally with cereals, and especially with winter wheats. Verzalization of the grains of a winter wheat so speeds up the completion of its life cycle that it can be grown as a spring wheat. Grains of the Turkey Red variety of winter wheat, for example, are verzalized by soaking to a moisture content of about 60%, which just permits initiation of germination, holding them at approximately that water content, and exposing them to a temperature of 33°–37° F. for 9–10 weeks before sowing. The plants developing from these seeds reach the heading stage in 110–120 days from the beginning of the cold treatment. Unverzalized seeds of the same variety require 150 days from sowing to attain the same stage of development in the same environment. This effect of low temperature treatments on pre-germinated seed, now called verzalization, has been known for many years, but gained new prominence beginning about 1930 because of its advocacy as a practical measure by Russian agriculturists. Because of the particular climatic conditions prevailing over large portions of Russia, the verzalization of winter wheats has proved an advantageous agricultural procedure in some parts of that country. In other parts of the world, however, verzalization has not proved to be a practice of commercial value.

Plant Movements.—The existence of autonomous movements in plants usually escapes notice because most of them occur too slowly to permit their detection by casual observation. That movements of plant organs actually do occur can be readily confirmed by a series of observations of certain plant organs under suitable conditions. The reality and vigour of plant movements can also be demonstrated strikingly by time lapse motion picture technique in which pictures of the moving plant organs are taken at relatively long intervals and the resulting film projected at such a speed that the movements are greatly accelerated. Most movements in the vascular plants may be classified into growth movements or turgor movements.

Growth movements, many of them curvatures of plant organs, result from differential rates of growth. Growth movements may be classed as tropic movements, nastic movements and nutations. Tropic movements such as phototropism occur under the influence of an environmental factor acting with greater intensity from one direction than another. Nastic movements are those in which the direction of the movement is limited by the structural symmetry of the plant organ. The more rapid growth of the upper side of a plant organ, such as a leaf or flower part is called "positive," the more rapid growth of its lower side "negative." Opening of flowers is caused by epinastic movements of the sepals and petals, closing of flowers, such as occurs in some species at night or at low temperatures, results from hyponastic movements of the petals. Careful observation of a growing stem tip reveals that it does not grow straight ahead through space, but

moves in an irregular spiral pathway as it elongates. Such growth movements are called nutations.

Turgor movements are those caused by reversible changes in cell volume. Many such movements result from turgor changes in structures called pulvini, located at the base of the blade or petiole, or both in some kinds of plants. The well-known and spectacular reactions of the sensitive plant result from turgor changes in cells of pulvini located at the base of the petiole and the base of each leaflet.

Phototropism.—When a plant, such as a potted plant on a window sill, is illuminated more strongly on one side than on others, the stems usually bend towards the brighter light. Two mechanisms of this phenomenon of phototropism have been recognized. One is a retarding effect of light on the elongation of the cells. Hence the cells on the more brightly illuminated side of the stem elongate less than cells on the opposite side, and the stem bends towards the light. The other mechanism of phototropism has been studied principally in the coleoptiles of grasses. Charles Darwin showed many years ago that, although bending occurs in the basal portions of a coleoptile, shading its tip with a tin foil cap prevents curvature of the coleoptile when unilaterally illuminated. Detipped coleoptiles likewise evince little or no phototropic reaction. Bending of the basal portions of the coleoptile is, therefore, subject to a controlling influence of the tip. Subsequently it was shown that auxin in the tip of an oat coleoptile migrates laterally across the tip from the more strongly illuminated to the shaded side. Some inactivation of auxin on the illuminated side may also occur. Since downward translocation of the auxin is almost strictly longitudinal, the cells on the shaded side of the coleoptile receive more auxin than those on the lighted side. The cells on the shaded side therefore elongate more than those on the illuminated side, and the coleoptile bends toward the light.

Geotropism.—If a potted plant be placed in a horizontal position, the stem bends upward away from, and the root bends downward toward, the force of gravity. These are examples of negative and positive geotropism, respectively. In a horizontally oriented oat coleoptile, auxin migrates from the upper to the lower side of the tip and thence longitudinally in the usual manner. The greater concentration of auxin on the lower than on the upper side induces greater elongation of cells on the former, and the coleoptile bends upward. In a horizontally oriented root tip, auxin also migrates from its upper to its lower side. Elongation of root cells is favoured by much lower concentrations of auxins than favour elongation of coleoptile cells, and root cell elongation is retarded at all higher concentration. A relatively high auxin concentration on the lower side of the root therefore results in a smaller elongation rate of the cells on the lower as compared with the upper side, and a downward bending of the root results.

PLANT ECOLOGY

Plant ecology is the science which deals with the interrelationships between plant life and environment. It is a segment of general ecology, the empirical basis of which lies in the common observation that living organisms vary with environment, and whose deeper foundations rest upon the fact that life and environment are inseparable parts of a greater whole. Other aspects of general ecology are animal ecology, human ecology and bio-ecology, which is defined provisionally as the ecology of plant and animal interrelations. Actually, plants, animals and men are so intimately associated that it is seldom possible for the ecologist to confine his attention to any one of them, although each special field has its own core of knowledge and technique.

This last statement can be emphasized by noting the following subdivisions or facets of plant ecology: (1) autecology, the relation of the individual species or plant to its environment, (2) floristics, the distribution in time and space of the various kinds (i.e., species, genera, etc.) of plants; (3) ecological plant geography, the distribution of plant communities; (4) plant sociology, or synecology, the characteristics of plant communities, (5) ecological measurement or habitat analysis, the analysis of the nonliving environment, (6) applied plant ecology.

Throughout the following discussion of these phases of ecology it should be kept in mind that earth, atmosphere, individual organism and communities of organisms all represent dynamic systems, or processes, whose mutual interplay is the concern of the ecologist.

Autecology.—This subject deals with the types of plant structure and behaviour characteristic of different habitats, and the capacity of plants to adjust themselves to various conditions. These are problems of structure and behaviour as well as of ecology, hence they involve the techniques of morphology and physiology. Genetics is also involved, since the attributes in question depend upon the inherited make-up of the individual.

It is a matter of common observation that plants of arid regions are very different from those of the temperate zone, in consequence of the different environmental conditions which they have to endure. The same is true of the distribution of plants in the different parts of the world. The study of autecology is concerned with the relation of the individual plant to its environment, and it is a branch of ecology which deals with the study of the characteristics of plant communities, and the study of the distribution of plants in the different parts of the world. The study of autecology is concerned with the relation of the individual plant to its environment, and it is a branch of ecology which deals with the study of the characteristics of plant communities, and the study of the distribution of plants in the different parts of the world.

Every species of plant inherits certain potentialities of adjustment to external conditions. The range of tolerance may be wide or narrow, and differs as regards different factors. The dandelion, which occurs under a wide range of temperature and mois-

ture conditions, has been observed to bloom during ten months of the year at Lincoln, Nebraska. But along the shore of Lake Michigan it thrives only on clay or where lime-bearing clays are mixed with beach sand.

Within the species are to be found varieties with special limits of tolerance. Upon these, as upon the species, environment may act selectively, eliminating in one place, sustaining in another.

A given factor, such as temperature or moisture, does not always act in absolute fashion. The reaction of a plant with respect to it may vary with other conditions. Thus by regulating water supply, etc., a plant may be hardened to resist cold.

Autecology also considers the numerous specialized adjustments of behaviour between different species of plants, or between plant and animal species. Into this category fall such problems as insect pollination, parasitism and mutual relations between legumes and nitrogen-fixing bacteria.

The course of organic evolution has led not merely to increased specialization of animals and plants, but to increasingly specialized relations between and among species of both. Thus the class of insects, although older than flowering plants, has developed to its present amazing complexity (over 500,000 species) along with the flowering plants, with which insects sustain a wide variety of intimate, often mutual relationships. Unquestionably the development of the flowering plants has been, in its turn, profoundly affected by the activities of these invertebrates. Similarly, the rise of hoofed grazing animals was inverted by the evolution of grasses and the consequent origin of great continental steppes. The grasses, in turn, have become adjusted to grazing as a factor in their normal environment.

Among the interrelations of plants none is more important than competition. The consequences of competition are evident in all plant communities, but the source and means of competition are a part of the subject matter of autecology. The general principle involved is that the intensity of competition increases as requirements become more nearly alike. This implies that competition should be most intense between individuals of the same species, which have practically identical requirements. Especially is this true of plants, since mutual benefit within the species does not appear so clearly among plants as among animals. Some measure of the intensity of competition can be seen in any normal woodland by comparing the density of seedlings, saplings and mature trees of any species. A single mature tree is likely to be the sole survivor of many thousand seedlings. Since the most critical competition is for light, water and soil nutrients, the ultimate adjustment among individual plants is attained through spacing, both of roots and tops. Secondary species commonly root at shallower depths and branch at lower levels than dominant forms.

The absence of mutual aid within the plant species is compensated for in part by the usually prodigious output of reproductive bodies, e.g., seeds, and by the development of often highly specialized means of dissemination, whose study is an important phase of autecology. Seed transport by wind, water and animals is a phenomenon familiar to anyone with the slightest knowledge of plants, and often attains great effectiveness. Hard seeds of edible fruits not only pass through the digestive tract of animals without injury, but may actually germinate better for doing so. The eccentrically weighted fruit of maple acquires in falling a spin which may project it to a considerable distance from the parent tree. The coco-nut, although it cannot germinate after prolonged immersion in salt water, appears to have been transported, by means of ocean currents, to every oceanic isle capable of growing it.

The term "adaptation" is frequently used with respect to autecological adjustments. It should be employed, however, in such a way as not to confuse (a) the fitness of plants which have become adjusted by selection to a given environment, and (b) the plastic adjustments which a given species can make to variations within an environment to which it has long since been generally fitted by selection.

Autecology has numerous practical applications, e.g., in the

selection of drought-, frost-, and disease-resistant varieties of economic plants. It is also of value in diagnosing the character of a habitat under conditions where instrumental studies are not available. Commercial use has been made of it in selecting sweet corn strains with very tight husks through which the larvae of European corn borer can not penetrate to the tender grains within.

Floristics.—With the possible exception of certain microscopical plants, every species has a limited and characteristic range, although there is wide variation among species in extent and continuity of their range. The same statement may be made of larger groups, the genera and, to a considerable degree, of families. Groups with greatly restricted range, such as the genus *Sequoia* which is confined to California, are known as endemic. The opposite extreme is represented by cosmopolitan forms such as the common dandelion.

The pattern of distribution of plant families and their subdivisions finds its explanation in terms of organic evolution and subsequent migration. This migration, in turn, has been subject to changing conditions of earth, climate and biological influence. Theoretically, the older a group, the more extensive should be its distribution, but this principle is subject to so many modifications that every instance has to be investigated on its merits. For example, the present endemic genus *Sequoia* referred to above was once widespread.

Thus a study of floristic patterns must take account of the past as well as the present. It draws upon geology and climatology for explanations, and in turn is a source of valuable clues to students of these subjects by suggesting the position, in time and space, of pathways and barriers. These latter are dependent upon changes of land and water area, changes in land elevation, and shifts in climatic centres.

The term "continental pairing" is sometimes employed to describe the rather frequent appearance of a genus, or even a species, on two continents. Thus closely related forms are to be found in eastern Asia and in North America—a fact correlated with the recent existence of a land bridge in the Bering region and a uniform, favourable circumpolar climate. Similar relationships exist between the floras of Europe and North America and those of Asia and Africa.

On the other hand, members of families common to Africa and South America, or to Australia and other continents of the southern hemisphere, exhibit more distant relationship and hence point to more remote opportunities for migration and to barriers of greater antiquity. These facts are parallel with data obtained from animal distribution—for example, the relatively ancient separation of old and new world marsupials and primates.

The most obvious climatic influence on plant distribution is that of temperature. Few species of seaweeds, if any, have a zone of distribution exceeding a difference of ten degrees in mean annual isotherm. Land species are subject to similar limitations, plus those due to differences in supply of available moisture. Hence continental desert areas may form barriers as effective as mountain ranges or seas.

Numerous biological factors also influence migration of plant species. Apparently the *Yucca* will tolerate a wider range of conditions than the *Promethes* moth which is essential to its pollination and seed formation. Thus its natural range is limited to that of the symbiotic insect. Again, the evolutionary development of more efficient species will drive older, less efficient species from areas to which they are well adjusted, and hinder their return. This is exemplified in the relation between conifers and deciduous trees in the humid temperate parts of the northern hemisphere. The former, though quite capable of growing in such regions, have been relegated to the less productive margins. Also, the presence of lethal parasites may exterminate a particular species throughout a portion of its natural range especially favourable to the parasite, and thus establish a lacuna or barrier.

The reciprocal relation between human cultures and plant species is of extreme importance. The three great centres of primitive agriculture—eastern Asia, Asia Minor and Central America—are correlated with the original location of three grasses—rice,

wheat and maize, respectively. In the subsequent migrations of these and other economic plants, and of numerous ruderals, it is to be found much of the record of the shifting of human cultures.

While the subject of floristics deals with the distribution of all species of the plant realm, the greatest interest attaches to seed plants, which are the dominant forms of modern plant life. Considerably more than half the known families are represented within the tropics, which have afforded more or less continuous refuge during periods of climatic stress in more temperate regions. Flowering plants, well established during the Cretaceous, evolved into a wealth of species during the ensuing Tertiary and became widely distributed during that period of comparatively widespread favourable climate. Present patterns of distribution of this great group and the somewhat older conifers are largely due to the impact of glacial Pleistocene conditions upon this Tertiary pattern.

Pleistocene glaciation involved at least four major advances of continental ice sheets, with three more or less prolonged interglacial periods. The comparatively brief time since the last retreat (c. 15,000 years), although usually referred to as postglacial, has exhibited some of the qualities of an interglacial period, and at no time since the Tertiary have the mild conditions of that period been attained.

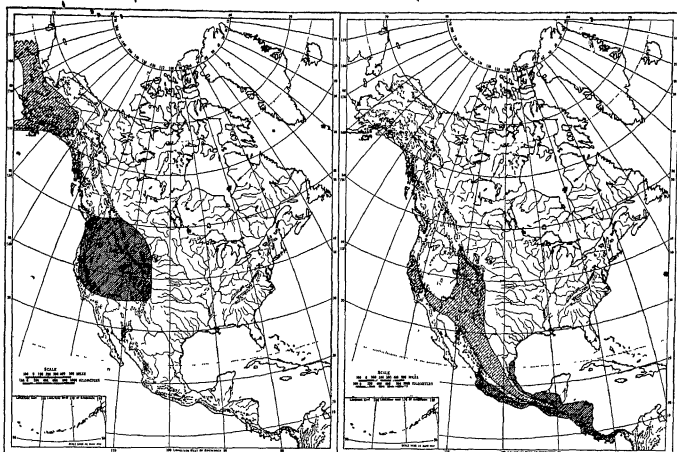

During the Tertiary a remarkably rich temperate flora had become diffused to high latitudes in both hemispheres and may properly be described as circumpolar. This flora was compelled to retreat toward the tropics by the advance of Pleistocene ice. With each glacial recession some of the lost territory was recaptured, to be lost again with successive advances of the ice. The effect of this upon the Tertiary flora was less disastrous in North America than in Europe, where southerly retreat encountered obstacles, and where today the deciduous forest flora is relatively poor in species.

Glaciated portions of the northern hemisphere exhibit three groups of disjunct species of great interest. (1) boreal species in now temperate southerly regions; (2) southern plants occurring in isolated stations north of their present main range; and (3) continental steppe or grassland species in more humid or oceanic regions than they normally occupy. The boreal species, notably bog plants, are now usually regarded as true relicts left behind following the last glacial retreat. The northern offshoots of southern plants are still a subject of controversy. One school holds that they represent vegetation which persisted in place on nonglaciated elevations or nunataks throughout glaciation. Critics of this belief hold that this was impossible, questioning the nunatak nature of the areas in question and also the ability of southern plants to survive the glacial climate. Both botanists and geologists are divided in opinion.

In view of this problem, the third group of disjunct species takes on considerable interest. There is a growing belief that they represent relicts from a postglacial time that was warmer and drier than the present—a so-called xerothermic period or periods. Given such climatic conditions and a suitable pathway for migration—for example, the formerly elevated but now submerged Atlantic coastal shelf—southern plants may well have moved northward, leaving relicts behind them during the subsequent cooling and subsidence. At any rate evidence is accumulating from a variety of sources, including modern glaciers and microfossils in peat deposits, to substantiate the existence of postglacial xerothermic conditions.

While the chief contributions to floristics are made by students of plant classification (taxonomy), the knowledge itself is an essential segment of ecology. For example, composite maps of the ranges of characteristic plants of great formations reveal with clarity the dynamic centres of climate and plant distribution in such regions as the eastern deciduous forests and tall-grass prairies of North America and the Mediterranean zone of Europe.

Moreover the Danish botanist, C. Raunkjaer, has developed a method of climatic analysis through floristic lists of any region. He has classified plants according to the depth of burial or height of exposure of their delicate perennial growing points. Each species falls into a definite category according to the degree

FROM R. W. CHANEY, "PLANT DISTRIBUTION AS A GUIDE TO AGE DETERMINATION" FROM "JOURNAL OF THE WASHINGTON ACADEMY OF SCIENCES"

FIG 14.—SHOWING DISTRIBUTION OF SUBTROPICAL AND TEMPERATE FOREST UNITS DURING THE CENOZOIC OF WESTERN AMERICA. LEFT, EOCENE. RIGHT, RECENT. IN BOTH MAPS, CLOSELY SPACED CONTINUOUS LINES INDICATE A SUBTROPICAL, AND BROKEN LINES A TEMPERATE FOREST

of exposure or protection, and the percentage of species in each category constitutes what he calls the "biological spectrum" of a given regional flora. By comparison with a standard spectrum which he has devised, inferences may be drawn concerning the climatic characteristics of a region whose flora has been thus analyzed.

Ecological Plant Geography.—Much that has been said concerning the distribution in space and time of species will apply to communities of plants as well. For a discussion of the nature of communities, see *Plant Sociology* below.

The major communities of the earth can be grouped roughly as follows: (1) *tundra*, or treeless, largely moss and lichen vegeta-

tion. Climates fluctuate in the intensity of their expression from year to year, and consequently in their marginal effects.

Rapid increases in elevation result in a telescoping of climates within comparatively small areas. Thus in ascending a mountain one may pass through plant communities expressing climates which on level terrain might encompass many hundreds of miles.

Any map of world formations must be generalized to a high degree, yet inspection of such a map reveals the transitions from extreme oceanic to extreme continental climates except in circumpolar regions where temperature becomes the limiting factor. The failure of such maps, in temperate and tropical regions, to correlate more exactly with conventional rainfall maps is due to evaporation, a quantity not generally measured by the meteorologist, but one of critical importance to vegetation.

Ecological plant geography is a subject of the highest utility in its bearing upon world resources and industries and in its indication of proper types of land use and management. It is likewise a factor in military strategy.

Plant Sociology.—In its broad sense this term is equivalent to synecology, or the study of vegetation rather than the individual plant, or the physical factors of the environment. It is sometimes employed to indicate particular techniques of statistical study. Whereas flora represents the "sum total of plant species," vegetation refers to the aggregate of plant life in terms of the communities into which it is organized. Beginning with the great formations already referred to, vegetation may be subdivided into communities of descending rank and of distinctive character at each level.

Difficult problems of nomenclature and classification are involved here, including the old Aristotelian problem of the specific thing and the form which it represents. The deciduous forest of eastern North America may be designated as the oak-beech formation, which in turn includes the maple-beech, oak-

mate, thus producing microclimatic differences, and for soil (edaphic) conditions which modify the availability of water and nutrients or impose unusual chemical limitations.

For such reasons, the actual boundaries between formations are seldom smooth and unbroken. Rather they are lobed and interdigitated, resembling peninsulas and chains of islands. As Asa Gray put it, there must be debatable borders between regions where slight incidents will throw the balance either way.

hickory, and oak-chestnut associations. These associations again may be divided into faciations (white oak-black oak), consociations (bur oak), and these latter into societies of subordinate species. More formal systems, involving Latinized terms, are also employed. In general the more refined a subdivision, the more homogeneous its character.

The attributes of a plant community are structure (the growth forms present—e.g., trees, shrubs, grasses—and their relative arrangement), composition (the species present), and development (life history or succession). Thus a forest is dominated by trees of one or more species, the individuals exhibiting definite spatial relations to each other. In the environment thus controlled, characteristic undershrubs, seedlings, vines and herbs occupy suitable niches. Equally essential, although less conspicuous, are the fungi and bacteria which utilize the materials formed by the dominant vegetation and by decay return these materials for re-use by green plants. Characteristic parasites and symbionts are also part of the community structure, and so are its animals as well. Such a structure may vary greatly in floristic composition, depending upon the species present in the region. The forests of Asia and North America are similar in structure, but composed of different plant families.

One of the most fruitful discoveries in connection with plant communities is the fact of succession or development. This can be simply illustrated by the changes which occur on an abandoned field, a bare rock surface, or a sand dune from the first invading pioneers to the final stabilized forest or prairie. Succession involves change in both structure and composition and moves toward a condition of relative equilibrium characterized by little change in either respect, and known as a climax community. The test of a climax community lies in the ability of the species composing it to reproduce themselves under the conditions which they so largely determine. Pioneer and subclimax species do not have this power. In principle a climax community, once established, maintains itself unless disturbed by physiographic, climatic, or biological (biotic) change. Such disturbance for example would result from serious erosion, uplift or depression, shift in available moisture or temperature patterns, evolution or immigration of new species, fire, clearing, drainage, disease, etc. Succession represents a process of increasing integration between life and environment. It apparently tends to follow the principle of Le Chatelier as developed by Bancroft, *i.e.*, heterogeneous systems tend progressively toward a condition of minimum disturbance by external forces and internal stresses. So far as the somewhat limited evidence goes, succession also tends toward a progressively more efficient use of energy. The climax community is a close-knit and delicately balanced system which stores and uses solar energy. So intimately adjusted are the nutrient and reproductive cycles of its constituent organisms that the minimum of useful energy is wasted in the chain of metabolic relationships. Thus the climax community represents the maximum in organic economy, as contrasted with the extreme of energy waste in a bare area which receives solar energy only to dissipate it into space without benefit to living organisms.

Representing thus the maximum capacity of a landscape for sustained production, the climax community affords a scientific norm of great value to man in the planning of land use and management and, by analogy at least, in the organization of his own communities. For this reason, quite as much as for sentimental and aesthetic considerations, it is important that in civilized and heavily populated areas substantial remnants of natural vegetation should be set aside, preserved and permanently protected from disturbance. Such reserves or nature sanctuaries are to be distinguished from parks set aside for recreation, and from public forests managed for economic yield.

There is, unfortunately, some difficulty among ecologists in arriving at an agreement regarding the exact meaning of the word "climax." For practical purposes the climax plant community might be regarded as the limit toward which the vegetation of a given climatic area and a given evolutionary composition tends. This definition is chiefly convenient because the changes in climate and evolution are slow in terms of human ex-

perience. Against them as a background, succession involves the operation of three other dynamic processes (1) physiographic change, (2) soil development and (3) biological interaction.

Physiographic Change—The youthful landscape is typically marked by strong contrasts of elevation, which for a time are increased by the rapid downcutting of narrow stream valleys. This tends to diversify the effect of climatic conditions, producing extremes of shelter in ravines and depressions, of exposure on uplands, and marked differences in available soil moisture throughout. As topography matures, valleys widen, depressions fill and uplands are lowered, thus lessening the initial contrasts. The limit of this process is represented by the peneplain, a generally uniform physiographic system over which local modifications of climate are at a minimum. Until this mature stage of topography is reached, the stability of any community within the landscape is provisional, and its climax character is relative, subject to completion of the erosion cycle.

Actually the peneplain condition is not often attained. Tilting, warping and uplift often interrupt the orderly progress of the erosion cycle, rejuvenating the landscape and interrupting the course of plant succession. Moreover, the rate of erosion and deposition is significantly modified by the presence of vegetation. This can be observed by comparing the sharp and rugged topography of a thinly clad desert or semiarid terrain with the gently rounded hills of a heavily vegetated humid region. By removing natural vegetation and substituting cleared-till fields, man has become a prime agent of geological change, inducing as much erosion in a few decades as might occur in a millennium under natural conditions.

Soil Development—Soil represents not merely the finely divided rock of the earth's surface, but the underground extension of community action and influence. This activity results in a physical, chemical and biological organization of the soil of which the structural expression is the soil profile. The soil profile is studied by means of trenches, or along road and stream cuts, and accurately records the character of the particular climate and vegetation. Thus a forest soil profile is characterized by a thin, very rich and acid surface layer of black humus formed by the fungous decay of fallen leaves and other organic debris. Beneath is a light layer from which the acids have leached soluble mineral material, and below that the layer occupied by tree roots, from which they draw mineral nutrients that are subsequently dropped on the surface by falling leaves, branches, fruits, etc. By comparison, a grassland soil profile exhibits a dark humus layer often 36 in. or more in thickness, measuring the depth of penetration of the abundant fibrous roots and the accompanying microorganisms and fauna. In consequence of these differences cleared woodland soil quickly loses its shallow, rich surface layer with careless handling, while prairie soil can endure longer periods of exploitation. The latter, on every continent, is particularly suited to cereal production, and from it comes the bulk of such staple foodstuffs.

Thus the soil profile is an expression of the energy which activates the living community, and the organization of the profile indicates the capacity of the area to sustain life under current conditions. It should be noted that this organization represents an accumulation of solar energy, manifesting itself in the accumulation and mobilization of materials, and facilitating the work of living organisms. The accumulated energy in soil is analogous not so much to the power which runs a factory, as to the energy used in its construction and equipment. Soil development is clearly a most important phase of community succession. And in the same way that physiographic processes tend to minimize the initial differences of a given climatic area, soil development tends toward uniformity throughout such an area.

Biological Interaction—The influences of vegetation and habitat are mutual and continuous. Yet it may be said that the influence of the physical environment is at a maximum under pioneer conditions, while that of vegetation is greatest at climax. The pioneers in a new or "raw" habitat usually encounter extremes of physical and chemical conditions, and frequently violent fluctuations in those conditions. For example, successful pi-

ioneer plants must be adapted to withstand high intensities of light usually characteristic of such habitats. But these plants produce shade, which is unfavourable to their own seedlings, and they are replaced by species more tolerant of shading.

Pioneer habitats likewise often present extremes of moisture or dryness. The growth of pioneer plants, adjusted to such extremes, increases humus and modifies the local water balance, a circumstance which operates in favour of plants which, while less hardy than the pioneers, are much more efficient than their predecessors under the new conditions which those predecessors have brought about.

An exceedingly important aspect of this process is the role played by animals and microorganisms, through competition and through the mutual adjustments between dominant and secondary species belonging to the same stage of succession. Like the processes of physiographic change and soil development, biological interaction is convergent in character, leading from initial heterogeneity to ultimate homogeneity. Thus, in the north central states, such varied habitats as dunes, ponds, bare rock and clay ridges have their distinctive pioneer vegetation. Each passes through a characteristic sequence beyond this stage, approaching in structure and composition the beech-sugar maple forest—a relatively stable and self-perpetuating community. Numerous instances are on record of beech-maple climax forests which have developed on each of these types of initial areas; on the other hand a lag in physiographic change or soil development may arrest the sequence for a long period at some subclimax level. Thus the moist shaded northern face of a steep hill may reach the climax condition while the hot dry southern exposure remains covered with the subclimax oak and hickory.

Problems of technique in the field of plant sociology have been quite as troublesome as those of nomenclature. Mapping, both topographic and two-dimensional, is of course essential. Aerial photography has been an invaluable aid.

Within the community itself the problem of expressing quantitatively the relationships which exist is extremely complicated. In addition to relative abundance of various species, their cubic magnitude, both above and below ground, may be significant. Typical concepts used are frequency, coverage, constancy, presence. Since the end of quantitative study is always a qualitative judgment, the choice of particular techniques of counting and measuring varies widely with workers and with the nature of the communities studied. Thus in grassland and herbaceous communities the use of standard quadrats, or squares of uniform size for sampling and comparison, has been extensively developed. In forest regions quadrats of larger size are necessary to give adequate sampling.

Since plant succession is at best a slow process, it must ordinarily be demonstrated by a combination of more or less indirect and inferential methods. Prevalence of vigorous juveniles of species different from the existing dominants is strong evidence of the direction of succession. The zonal distribution of plants, as, for example, about a senescent lake, often indicates the sequence of advance of land vegetation into the lake bed. Comparison of numerous related communities in different stages of development is also a fruitful method. Records, whether palaeobotanical, archaeological, or historical, often afford valuable clues. Direct proof is increasingly afforded by the growing length of scientific records.

Ecological Measurement, or Habitat Analysis.—These terms are employed in the absence of better ones to designate evaluation of the nonliving factors of the environment. The ecologist here depends upon techniques borrowed from sciences which deal with earth and atmosphere. Not infrequently he contributes to these sciences in return, as is evidenced by the recently growing attention given to evaporation by meteorologists.

It is an axiom that the living community is the most perfect expression or integration of the physical environment. This has led to considerable use of plant communities as indicators of conditions which cannot conveniently be measured otherwise, as for instance, depth of water table. Individual species are also used as indicators.

It is essential, however, that the physical environment be understood as accurately and completely as possible. This is well exemplified by the problem of the North American prairie. For a century able scientific men had propounded explanations as to the absence of trees on the prairie. More than a score of theories were advanced, including such suggestions as fire and soil. It was not until after 1910, and then as a result of patient instrumental studies, that proof was obtained that the lack of available moisture is the limiting factor for tree growth in the main body of the grassland. This had been frequently surmised, but never before established.

For the greatest value, ecological measurements should be continuous and inclusive. Light, humidity, precipitation, temperature, evaporation, wind movement and direction are the atmospheric factors most important. Moisture, temperature, texture and chemical composition are the corresponding soil properties. Automatic recording instruments, such as the hygrothermograph, must be employed, supplemented by frequent determinations for such factors as are not adapted to automatic measurements.

The earlier ecological methods of studying light only measured the intensity of actinic rays. Improved means are now available which measure both intensity and quality for a wide range of the effective spectrum. Also important is the photoperiod, or relative length of day and night. Measurements for evaporation have until recently given only relative figures, which could not be integrated with rainfall data. Improvements under way (1944) promise to give means for direct and absolute determination of the evaporating power of the air.

In the study of environment the "principle of limiting factors" must constantly be borne in mind. It is empirically expressed in the proverb "a chain is no stronger than its weakest link," and was recognized by Baron Justus von Liebig in his study of soil fertility by his "law of the minimum." In 1905 it was placed upon precise experimental basis for plant metabolism by F. F. Blackman, who stated that the rate of photosynthesis was conditional upon the least favourable of the several factors necessary. Depending upon local conditions, moisture, acidity, nutrients, temperature, light, etc., may be the controlling or limiting factor in a given habitat for given plants. The object of much ecological measurement is to determine limiting factors.

Ecological measurement has been sufficiently perfected to give material aid in predicting the hazards to be encountered in critical areas under various types of land use and management. This technique can be of the greatest economic importance in semi-arid regions, such as the high plains of North America.

Applied Plant Ecology.—Illustrations of the economic uses of ecology have been given in the preceding sections. With few exceptions, however, such applications have been sporadic. At the first Imperial Botanical conference, held in London in 1924, systematic plans were laid for the employment of ecology in developing new parts of the empire. With the encouragement of General Jan Smuts, this conference has borne fruit in Africa. The Russians have made intelligent use of ecology, although there is reason to believe that parts of the steppe area have suffered unduly from exploitation. The United States department of agriculture, including the soil conservation service organized in 1935, is making increasing use of ecology.

Yet it is probably far to say that among public men, and among the general population, there is yet little realization of the basic importance of this subject in establishing permanent and healthful relations between landscape and population.

In the problems of land use and management, ecology occupies a role analogous to that of physics and chemistry in modern industry. Such problems must increasingly be solved by the rigorous application of the principles of ecological science.

Man is the beneficiary not only of a prolonged process of organic evolution which has provided him a great variety of useful plants and animals, but of prolonged and continuous activity by plant and animal communities. This has resulted in the development of fertile soil, as well as in forests and grasslands whose products are no less essential to man than those of his

cultivated fields. Moreover, natural vegetation maintains a cover which stabilizes the earth beneath him and retards the violent action of frost.

Natural communities are characterized by a positive or favourable energy budget. Many, perhaps most, areas controlled by man are exploited, resulting in a negative energy budget, the final mark of which is unproductiveness and abandonment. The fundamental problem of applied ecology therefore is to assay various landscapes offered by man and determine whether they are registering a net loss or gain in efficiency. The simple criterion of cash returns cannot be applied here. The next problem of the ecologist is to assist in devising methods of land use suited to the character of the locality so that a favourable energy budget may be maintained or restored.

Due to the character of our political system and our long habit of using science chiefly where immediate problems of health or profit are involved, the fundamental application of ecology cannot be hastily achieved. In practice, however, growing numbers of civil servants—foresters, county agents, agricultural engineers, entomologists, etc.—are acquiring some understanding of ecology. The same thing is true to a lesser extent of farmers and farm owners. As this knowledge becomes more general, it will materially affect practice and planning, and has in fact already done so in favoured localities.

In the field of land management, or actual operation, ecology also has important functions, some of which have been suggested in preceding sections.

PATHOLOGY OF PLANTS

Plant pathology (or Phytopathology) is that branch of biological science which treats of the diseases of plants. While there can be no doubt that diseases of plants, and in particular of cultivated plants, have manifested themselves from time immemorial, it is only within comparatively recent years that their study has been taken up in an organized and scientific manner. The application of the scientific method generally to the study of practical agricultural problems is a development scarcely older than the 19th century.

Historical.—In view of the devastating effects of plant disease, especially when the particular plant attacked is of primary importance as food for mankind or his domestic animals, it is not surprising to find that references to epidemics of disease are not uncommon in historical writings, even of remote times. The earliest records are to be found in the Old Testament (e.g., Deut. xxvii, 22, 1 Kings viii, 37) under such terms as "blasting" and "mildew." The precise nature of the diseases referred to cannot now be determined but there is little doubt that some of the epidemic diseases of cereals, such as rust or mildew, are indicated. The ravages of insects are frequently noted, such as for instance plagues of locusts, caterpillars and canker-worms.

In Greek literature we find references to plant diseases in the writings of Aristotle, and more particularly in those of his pupil Theophrastus, the father of botany. The latter describes diseases of a number of cultivated crops, such as various legumes, cereals, fig, olive, etc., and observes that varieties of the same crop may show different degrees of resistance to disease. This is probably

the first mention of the idea of "resistant varieties" which figures so largely in present day writings on the subject. Among Roman writers the younger Pliny, who flourished in the 1st century of our era, devotes some attention to the subject and makes a number of well-founded observations regarding the incidence of certain plant diseases.

The middle ages were for plant pathology, as for all other sciences, dark ages and we have to come down to the Renaissance, with its general quickening of interest in all intellectual pursuits, to find evidence of further progress. The 17th and 18th centuries witnessed considerable activity in the study of plant diseases. The new studies proceeded in the main from two different directions. The practical gardener or agriculturist was chiefly concerned in describing the various diseases to which his crops were subject and in attempting to evolve methods of treatment. On the other hand, the student of human pathology was interested in the diseases of plants from the possible analogies to his own problems which such a study might offer. The whole science of botany had in the old days a distinct medical bias. It is not surprising, therefore, that the study of plant diseases has been to a large extent modelled upon the older science of human pathology, the terminology of which has been freely borrowed.

The elucidation of the real nature of plant disease, from the point of view of the causal agent, is mainly dependent upon the perfection of the microscope. But even the extended powers of observation which the use of that instrument brought to bear on the subject did not at once lead to a correct appreciation of the true nature of plant disease. Various structures were observed and accurately figured in detail as being associated with the diseased parts, but they were interpreted as portions of the plant which had become changed by the disease and not as belonging to a distinct organism which was responsible for the disease. The first incontestable proof that a specific plant disease was due to the invasion of the tissues of the plant by a definite parasitic organism was furnished by the German scientist, De Bary, whose pioneer researches prepared the way for a host of other workers, at first chiefly in Germany, and later in all civilized countries. The 20th century has witnessed an extraordinary activity in the study of problems of plant disease, most strikingly, perhaps, in the U.S.A. The economic importance of the subject, as a branch of scientific agriculture, has become increasingly recognized and the prosecution of plant disease researches is being more and more taken up by government departments in all countries possessing a progressive agriculture.

Definition and Scope.—While it is true that the distinction between a healthy and a diseased plant is often perfectly obvious, it is not easy to frame a definition of the diseased condition which will meet all cases. The border line between health and disease is not always sharply marked. It will be shown below that the majority of plant diseases result from the invasion of the plant tissues by a definite organism, the *parasite*. Nevertheless, the presence of a parasite does not always necessarily mean disease in the common acceptance of the term. For example, the root-nodules of leguminous plants (pea, bean, clover, etc.) are produced by the attack of an organism—a bacterium—and far from producing damage, the presence of the bacterium is essential to the proper development of the plant. The important part played by certain fungi in the germination and subsequent growth of many plants, such as orchids and heaths, is a further illustration. The living together of two organisms does not necessarily produce injury to either partner, in which case one speaks of a *symbiotic* relationship. Every gradation may be traced from the purely symbiotic type, in which the two partners are benefited or not obviously injured, to the distinctly parasitic type in which one partner thrives at the expense and to the detriment of the other. In fact both types of relationship may be shown between the same two partners—that is, a symbiotic or harmonious relationship is at first set up, but by and by one of the partners suppresses the other and the relationship becomes one of parasitism. There is thus a gradual transition from a condition of health to one of disease.

So far reference has only been made to the diseases of parasitic nature. Over and above these there is a class of diseases in

which no parasite is present at all, viz., the so-called *physiological diseases*. The existence of the latter increases the difficulty of defining disease in terms of the causal agent.

Perhaps the most adequate definition is obtainable by considering the normal development of a plant. Over a certain range of conditions, which one reckons as normal, a particular species of plant develops in a certain way—e.g., has a certain appearance, reaches a certain size, and so on—all of which are the reflection of a normal physiology or functioning of the plant. If now a particular individual diverges from the normal and if the abnormality impairs the functioning and more especially imperils the life of the plant, that plant may be considered as being diseased.

From the purely practical or economic point of view, a satisfactory definition of disease presents no great difficulties. Any given crop is grown in the expectation of a certain yield, both as regards quality and quantity. Disease in its economic aspects may therefore be defined as a condition of the crop in consequence of which it fails to give a satisfactory yield.

General Classification.—Diseases, whether of plants or animals, may be classified on the basis of the symptoms produced or of the causal agent concerned. For reasons given more fully below, the latter system of classification is more generally adopted in connection with plant diseases, and it is convenient to give at this point a general classification along such lines in order to limit the scope of the present article.

Classified on the basis of the causal agency, plant diseases are as follows—

- (1) Non-parasitic diseases due to nonliving features of the environment.
- (2) Virus diseases due to an infectious principle, a so-called virus.
- (3) Parasitic diseases due to other living organisms.

The first group includes those troubles in which the disease symptoms can be related to certain physical or chemical features of the environment. The second group includes those troubles caused by an infectious principle, a "virus," which may be trans-

mitted in various ways from diseased to healthy plants. The third group, in its broadest sense, includes all disturbances due to the attacks of other organisms, either animal or plant.

The depredations of most animal organisms, e.g., mammals, birds and snails, are considered by economic zoology, while the injuries from insects and mites to plants is within the field of economic entomology. (See *ENTOMOLOGY Economic*.)

The field of plant pathology as now generally recognized includes all of the non-parasitic diseases, the virus diseases and all troubles due to plant parasites and in addition those due either to eelworms (nematodes) or to protozoa.

Plant parasites may be bacteria, algae, fungi (including slime moulds) or higher plants. Plant diseases of bacterial origin were at one time believed not to exist, on account of the supposed fact that the acidity of plant juices is inimical to bacterial growth. Many bacterial diseases of plants are now known, some of great economic importance. The recorded cases of parasitism due to algae are few and unimportant.

Diseases caused by higher plants, some of which will be cited later, are on the whole of greater scientific interest than of economic importance. The fungi (*q.v.*) are by far the most important group of disease-producing organisms, so far as plants are concerned.

Broadly speaking, therefore, the plant pathologist is by training either an entomologist or a mycologist. As far as diseases of parasitic type are concerned, only those caused by plants, and therefore chiefly of fungal origin, will be dealt with in the present article. At the same time it is important to note that the two aspects of the study of plant disease, the entomological and the mycological, cannot in practice always be separated.

Symptoms of Disease.—The study of symptoms is the first step in the examination of a disease problem. By symptoms one means the total of the modifications shown in the plant as the result of disease. In the majority of plant diseases of parasitic type the true symptoms are accompanied at one stage or other of the disease by certain appearances such as the fructifications of

the parasite

A very important difference between the typical plant disease and the typical animal disease is as regards the definiteness of the symptoms shown. In animals and especially in man disease symptoms are usually very characteristic, so that it is often possible to identify (or *diagnose*) a particular disease from a study of the symptoms alone. With plants this is not generally possible. Disease symptoms in the latter are much more generalized, *i.e.*, the same or approximately the same symptoms can be produced by a great variety of causes. Wilting of the foliage, for example, is a symptom of disease in plants and its cause may be most varied—damage to the roots by fungal or insect attack, damage to the stem, presence of injurious salts in the soil, scarcity of water, and so on. Hence it follows that while a study of the symptoms may give valuable indications of the nature of a particular plant disease, it is in general necessary to discover the cause or *aetiology* of the disease before the latter can be definitely identified. Determination of the causal agent may be difficult and usually involves considerable expense of labour and time.

While the main symptoms of plant disease are of a rather generalized nature, a number of different types may be distinguished. The more important of these are given in the following list.

(a) *Change of colour*, such as paleness, silvery, reddening, blackening of leaves. The change of colour may be shown over the leaf or even over the whole plant, or it may be limited to spots, streaks or patches, such as the well-known "mosaic" appearance.

(b) *General wilting* of the shoot, as when the plant suffers from drought, or from "damping off" disease, or from the effects of a parasite which destroys the roots or is present in the water-conducting system.

(c) *Premature shedding* of leaves, blossoms, fruits, etc.

(d) *Abnormal retention* of leaves, which is especially well shown in certain diseases of deciduous trees. The autumnal shedding of leaves is a vital or physiological process, due to the action of a definite *absciss* or cutting-off layer at the base of the leaf. If this layer is prevented from functioning, as for example by the killing action of a parasite which has invaded it, the leaves cannot be shed in the normal way.

(e) *Dwarfing or stunting*, which may be general to the whole plant or may only be shown in particular organs.

(f) *Abnormal enlargement or multiplication* of parts (*hypertrophy*) resulting in the formation of such structures as galls, tumours, knots, warts, etc. (fig. 15). Hypertrophy is generally accompanied by distortion or malformation as in the rolling or puckering of leaves and the twisting of shoots. Frequently it takes the form of an abnormal development of buds, the majority of which would normally have remained dormant. The structures called "witches' brooms" (fig. 15) which are common on certain trees (*e.g.*, willow, birch) are produced in this way.

(g) *Replacement* of one organ by another, as for example the change of petals into foliage leaves. Some changes of this type, though properly speaking malformations, may be economically desirable and are therefore not considered as diseases. An example is the "doubleness" of some flowers.

(h) *Change of habit of growth*, *e.g.*, from the prostrate to the erect, from the climbing to the non-climbing type of growth (fig. 15).

(i) *Change in the periodicity relationships* of the plant, as for example the premature flowering ("bolting") of a biennial plant in its first year of growth, or the opening of foliage or floral buds at the wrong time of year.

(j) *Replacement* of parts of the plant by structures belonging to the parasite, such as the conversion of the rye grain into the resting organ (*sclerotium*) of the Ergot fungus (fig. 15). "Mummification" of certain fruits is another example of this type.

(k) *More or less rapid killing* (*necrosis*) of the plant or parts of it. Killing is often accompanied by more or less pronounced rotting, as in the decay of fruits, buds, etc. (fig. 15). Localized killing of portions of leaves results in the formation of dead spots. The killed tissue may remain as such or may dry up and fall out, thereby producing a "shot-hole" effect.

(l) *Formation of deep-seated wounds or cankers* (fig. 15). In

a canker, the parasite slowly eats into the plant tissue, the part invaded being killed and to a large extent disappearing. Associated with this type of wound there is usually a certain amount of hypertrophy of the tissue which still remains alive round the margin of the invaded part.

(m) Various kinds of *exudations*, as in the gumming of plum trees or the abnormal flow of resin in certain conifers.

METHOD OF STUDYING PLANT DISEASE

* Though the investigation of a plant disease is a matter for the specialist, a short account of the methods adopted will serve to indicate the type of problems encountered. The parasitic type of disease is in practice the one most frequently met with, and therefore in actual study it is usually assumed in the first instance that the disease under investigation is of parasitic origin.

Identification of the Parasite.—The first problem which arises is the determination of the nature of the parasite (assuming that such is actually present). The tissues of the plant which show the symptoms of disease are examined, after suitable preparation, under the microscope and if the disease is actually due to a parasite it is usually not difficult to demonstrate its presence. Definite indications of its nature and identity may also be obtained at this stage. In a number of cases, the parts of the plant which show the symptoms of disease may appear to contain no parasite, even though further study may confirm that the particular disease is of truly parasitic nature. Thus the parasite may be so small as to be beyond the range of microscopic vision (see *Plant Diseases Due to Viruses*, below), or, as occasionally happens, the parasite is located elsewhere but is able to produce symptoms in parts of the plant remote from it. The mere presence of a fungus or bacterium within the diseased part (or *lesion*) is not, however, a certain indication that the disease is caused in that way. Direct proof can only be obtained by inoculating healthy plants of the species showing the disease with the organism in question and observing whether the disease is thereby produced. The details of the procedure involved in the carrying out of such artificial inoculations will vary much in different cases. In general it is necessary, as a first step, to prepare "pure cultures" of the organism, that is, to grow the latter in such a way that no other organism is present. These pure or unmixed cultures of the organism are then tested separately by inoculations on the host plant, and by this means evidence is obtained as to which is the active parasite concerned. The active parasite being isolated and its pathogenicity (or capacity to produce disease) proved, one is now able to identify the particular disease in terms of the parasite which is responsible for it.

Identification of the disease is of value inasmuch as it enables the investigator to correlate his work with similar work done elsewhere, and of which a record is obtainable in the scientific literature. But mere identification is not the most important part of the study. It is essential to work out the *life-history* of the fungus—*i.e.*, to know where and in what form it occurs throughout the year. The same fungus may exist in a variety of forms in different situations or at different times of the year, and it is essential to connect up the various stages. In particular it is very important to establish the manner in which the fungus passes the winter (or equivalent) season. In temperate climates, for example, a summer growing season alternates with a period of dormancy during the winter. Often it is only on the actively growing crop in summer that the disease is observable. It reappears each spring, spreads during the summer, and becomes more or less latent during winter. The considerations which arise in this connection vary much in the different cases. A few examples will illustrate this. Annual crops pass the winter season in the form of seed. Is the disease therefore carried over the winter by means of the seed, and if so is it present within the seed, or is it carried on the surface? Or does it persist in the soil, or is the new crop infected afresh from dead remains (stubble, trash, etc.) of the preceding year's crop? Or again, do various perennial plants, such as certain weeds, serve to carry the disease through the winter? With perennial crop plants such as fruit trees, there is the further possibility that the disease may over-

winter in a resting form on or in the plant itself. The determination of the exact method of overwintering which obtains in any particular case is obviously of the greatest practical importance.

The further examination of a disease problem from the point of view of the parasite would take into consideration the geographical range of the latter. Plants showing the particular symptoms would be obtained from different localities and the parasites isolated and compared. Thus a general idea would be obtained of the geographical distribution of the parasite and of the range of host plants which it could parasitize.

The complete elucidation of a plant disease involves much more, however, than the determination of the existence and habits of a parasite as outlined above. The presence of the parasite is only one of the conditions essential for the appearance of a specific parasitic disease. The more important factors and the manner in which they operate will now be indicated.

Temperature.—This factor determines in large measure the rate of growth and general vigour both of parasite and host. There is a certain temperature (*minimum*) below which an organism will not grow, a *maximum* above which it will not grow, and an *optimum* at which it grows best. These three temperatures constitute the so-called *cardinal points* for the particular organism. The cardinal points for the parasite are not in general the same as for the host plant, and the cardinal points for the disease itself are not the same as those of either host or parasite. Usually the range of temperature over which disease takes place is distinctly narrower than that over which either of the two organisms concerned will grow. The optimum temperature is well known in many cases to be different for host and parasite, and thus it is clear that the possibility exists of finding a temperature at which the host plant grows well but which is unfavourable for the development of the disease. The precise relationships are somewhat complex and have been fully worked out for a limited number of diseases only, but it is possible in general terms to classify diseases into the two main types, high temperature and low temperature diseases. An example of each will show the difference. The root-rot disease of tobacco is one of the low temperature type. Susceptible varieties of tobacco when grown in infected soil are badly diseased if the temperature rules low, whereas in the same soil the disease would not occur at a higher temperature. The wilt disease of cabbage is of the high temperature type, and only occurs in seasons when the general ground temperature is high.

Water.—The water-relationships of the crop are of equal importance with those of temperature and are to be studied in terms of the amount and distribution of rainfall, the water-retaining capacity of the soil, drainage, etc. Two factors which are of great importance in the initiation of parasitic attack are the relative humidity of the air surrounding the plant and the percentage of moisture present in the soil. The parasite requires the presence of a certain amount of moisture to start its growth processes. So it will often be possible for the plant pathologist to explain the occurrence of disease at one time or place and not at another in terms of these factors. The percentage of moisture in the soil affects not only the capacity of the parasite to grow but also the growth of the roots of the plant. It may therefore also influence the capacity of the roots to resist the attacks of the parasite.

Light.—Light is also a factor which influences the susceptibility of a plant to disease. The quantity of light received by the plant determines in large measure its vigour of growth, not merely as regards the amount of new tissue formed, but also as regards the mechanical strength and to a certain extent the chemical composition of the tissues of the plant. These qualitative differences influence the degree of resistance which the plant can offer to the attack of a parasite. For example the weak, pale, rather juicy, "forced" type of growth which results when plants are grown under conditions of feeble illumination—as when plants are grown in glasshouses during winter or when they shade each other by standing too closely together—predisposes them to attack by a variety of fungi ("damping-off" diseases). On the other hand, certain fungi (e.g., some of the rusts) attack their hosts with vigour only when the latter are growing under conditions of good illumination. Again, the symptoms of certain diseases (e.g., some mosaics) will only appear when the plant is exposed to light of a certain range of intensity.

The three fundamental factors, temperature, humidity and light are, in the open field, to a large extent beyond control. Nevertheless, it is often possible, in agricultural practice, materially to modify their action. By suitable methods of cultivation—draining, subsoiling, ridging, manuring—the amount of soil water can be regulated. By the provision of shade trees—as is usual in many tropical cultivations—or by suitable spacing of the crop itself or by pruning, the intensity of light or humidity of the air can be adjusted so as to approximate to the needs of the plant.

Soil Factors.—Reference has been made to soil moisture as

a factor of importance in connection with plant diseases. This is merely one of the many soil factors which influence plant growth and which therefore require to be considered in dealing with the liability of plants to disease. The physical texture of the soil and the presence or absence of certain chemicals are of importance mainly inasmuch as they influence soil humidity. But there are in addition a number of soil factors which act otherwise. Thus the amount of certain constituents present in the soil (e.g., nitrogen, potash, phosphate) influences not only the quantity of plant growth but also, to an appreciable degree, its quality—and in particular its susceptibility to disease. The presence or absence of lime, by controlling the reaction of the soil, is in some cases the factor which determines whether a particular disease will develop or not. Soil aeration is a factor in itself, though in practice it is often difficult to separate its effects from those due to soil humidity.

Internal Factors.—So far the discussion of the factors which influence plant disease has been limited to the environment. The latter, however, merely modifies the result which is in the main conditioned by the structure and physiology of the host plant itself. These "internal" factors are more elusive than those already discussed and in their fundamental aspects are practically unmapped. A few examples of internal factors and of their manner of functioning will be given in the following section. Nevertheless, though very little is known of the underlying factors which determine immunity or susceptibility, certain phases of the problem are open to direct observation and experiment.

From the foregoing sketch it is clear that the complete investigation of a plant disease may ramify into various branches of agricultural science. The plant pathologist is thus much more than a mycologist, or student of fungi, though in practice the two names are often used as equivalent. Plant disease investigations may call for the joint work of the mycologist (or entomologist), the soil chemist, the physicist and the practical agriculturalist, and lastly—as will be shown more clearly later—the co-operation is required of the geneticist for the breeding of resistant varieties, and of the pure chemist for the preparation of chemical means of combating the disease.

NATURE OF DISEASE, PHYSIOLOGY OF PARASITISM

The discussion under this heading will be confined almost wholly to diseases of parasitic nature. The problems presented in parasitic disease are simpler inasmuch as the interactions of parasite and host plant can be studied under the microscope, and to a certain extent at least are amenable to chemical and physical analysis. For simplicity, the description will be confined to a disease of fungal origin.

The earliest phase of such a disease is the entrance of a fungal thread or *hypha* (see FUNGI for account of fungal structure). The fungus, usually in the form of a spore, germinates on the surface of the plant, or otherwise comes in contact with the latter. It then enters, either by naturally occurring openings (stomata, water pores) (fig. 16, B) on the surface or by boring directly through the skin or cuticle of the plant (fig. 16, C). Certain parasites, known as *wound parasites*, are only able to enter through openings or wounds which have been made by other agencies, e.g., insect bites, bruises due to processes of cultivation, frost cracks, wind damage, pruning wounds, etc. Then again dispute exists as to whether the actual process of penetration is effected by purely mechanical means or by the agency of some chemical substance which softens or dissolves the cuticular layer of the plant. Once inside the plant, the fungus progresses by sending hyphae through the tissue, either between the cells (*intercellular*) or into the cells (*intracellular*). The particular relationship shown—i.e., whether the hyphae are *between* or *actually in* the host cells—is more, or less characteristic of individual diseases. In many cases the hyphae of the fungus ramify between the cells of the host and here they send characteristic outgrowths (*haustoria*) into the cells themselves (fig. 16, D). These outgrowths are clearly the organs which enable the parasite to abstract its nutriment from the host cells.

While the fungus is progressing through the plant, the cells

of the latter in the neighbourhood of the parasite, or even at some distance from it, show a number of more or less characteristic changes. The total sum of these changes, it should be noted, constitute the symptoms of the disease. The details of the changes shown vary much from one disease to another, but broadly speaking one can distinguish two main types of disease, each with a characteristic set of host changes associated with it.

Generalized Parasites.—In the first type, the fungus secretes certain chemical substances into the surrounding host cells, with markedly destructive effects to the latter. The living contents (*protoplasts*) of the cells are killed and the walls which separate the individual cells (and which form the mechanical skeleton of the living plant) are softened or partially dissolved. The destructive principle exuded by the fungus is able to diffuse out into the host tissue and thus bring about killing of the latter well ahead of the growth of the fungus. Fungi of this type are therefore not parasites in the strict sense of the term, inasmuch as they are growing all the time, not on the living plant, but on parts of it they have previously killed.

This type of parasitism is relatively simple and crude. The fungus, so to speak, is in the nature of an assassin who kills and then plunders his victim. The essential part is the killing and this merely entails that the fungus must possess the necessary battery of substances for carrying out this process. In these respects such fungi and the diseases to which they give rise stand in marked contrast to the type which will now be described.

Specialized Parasites.—In the second type of disease, there is no rapid killing or rotting effect produced by the parasite on the host cells in the neighbourhood. The cells of host plant and parasite live side by side for a considerable time with no apparent damage to the former. Indeed it frequently happens that the presence of the parasite stimulates the host cells to unusual growth and activity. Thus the cells in the neighbourhood of the parasite, some of which are actually penetrated by the food-absorbing processes of the latter, are often found on examination to be more richly supplied with food reserves than are the normal cells removed from the zone of influence. If the part of the plant affected is a leaf or other green part, the stimulating effect produced by the parasite may often be seen in the more intense green round the margin of the invaded spot than elsewhere. The stimulating action in many cases takes the form of renewed growth on the part of cells which normally would not have grown further. In this way are produced the tumours, galls, warts, witches' brooms, etc., frequently associated with diseases of this type. Such parasitism illustrates the *symbiotic* relationship to which reference has already been made. The symbiotic relationship may persist for a considerable time, but by and by injurious effects supervene, leading to more or less extensive destruction of the host tissue.

The second type of parasitism is much more subtle in nature than the first. The method of attack adopted has no resemblance to that of the assassin but savours rather of the blackmailer whose interests would not be well served by the premature death of his victim. Up to a point the interests of blackmailer and victim are identical, and if the association leads to unusual industry on the part of the latter the final harvest is all the richer. In diseases of the second type an analogous behaviour is shown. The analogy can in fact be pressed more closely still. Fungi which produce the first type of disease are, like the assassin, not selective in their action. In diseases of the second type, on the other hand, a high degree of selectivity is typically shown.

Fungi which produce this specialized type of disease show specialization in other respects. Their food requirements are of a very particular nature, and on this account it is generally impossible to cultivate them on any medium other than the living plant to which they are specialized. The symbiotic relationship is apparently necessary, and if this is not developed, no effective parasitism ensues.

As fungal attack progresses, one usually finds that the parasite makes provision for its further distribution by the development of a fruiting or sporing stage. The spores may be formed within the tissue of the parasitized plant and are disseminated only when the latter is decomposed, as for example by rotting on the surface

of the soil. More generally the fructifications of the fungus are developed on or towards the outside of the plant, either emerging from the stomata or bursting through the outer skin (fig. 16, F). Many fungal parasites develop two kinds of spores. One of these is produced in profusion during the growing period and serves to spread the disease rapidly to new plants. This is the so-called summer spore, which is usually short-lived and germinates with great readiness when the environmental conditions are suitable. The second type of spore is usually produced later in the season. This is a resting form which typically will not germinate until after a certain interval has elapsed, and which in some cases requires exposure to winter cold before it is capable of germination. The resting spore is usually provided with a thick protective wall, and is capable of enduring long exposure to atmospheric conditions. Its function is to carry the fungus over the winter.

Immunity.—The preceding sketch of the progress of a successful parasitic attack would be incomplete without some reference to those features of the plant which confer resistance or immunity to disease. These are the "internal" (as apart from environmental) factors to which reference was made above. It was also pointed out that immunity to certain highly specialized fungi was really due to over-susceptibility.

It may be noted in the first instance that a plant may be immune in the practical sense for the reason that it merely *escapes* disease. Internally it may be just as susceptible as other plants which become badly diseased. The presence of water-drops on the surface, which enable germination of the fungal spores, is a necessary antecedent to attack. Many plants are enabled to escape attack on account of a property of their outer surface which prevents the adherence of water.

With fungi which penetrate the cuticle, the strength of the latter is obviously of importance, at least if the mechanical work of penetration is accepted. In many cases there is definite evidence that this factor comes into play. Thus certain fungi are only able to attack the young leaves in which a mature, fully thickened cuticle is not yet present.

When the fungus has actually entered the tissues of the plant, it must, if parasitism is to be effected, be able to live in the sap with which it comes into contact. Attempts have therefore been made to explain the susceptibility or resistance of a tissue in terms of the properties of the plant juices. Certain difficulties of a technical nature are met with in such investigations, e.g., it is not certain how far an extract which is pressed out from a plant is a true representation of the cell-sap originally present in the cells. Up to the present it has been possible only in a few cases to correlate the resistance of the host tissue to fungal attack with the anti-fungal properties of the plant juice.

The method by which the "killing" type of fungus breaks down the resistance of the host tissue is by excreting certain enzymes which partially dissolve the cell walls and kill the protoplast. These fermenters are highly specific in action; i.e., they are active on some tissues and not on others. The main factor in this connection seems to be the chemical composition of the cell walls.

So far we have dealt with possible chemical measures of defense. Many plants adopt a mechanical means of defense by laying down a protective layer of cork in advance of the parasite. The corking-over of an exposed or wounded surface is a common reaction of plants, and the same often takes place in response to the wound caused by a parasite. One or more layers of corky cells are formed somewhere along the line of separation between diseased and healthy tissue, and these act as a mechanical barrier to further progress. Any condition of the invaded plant which tends to accelerate this formation of cork increases the resistance to attack, and conversely. Similarly it has been shown in one case (the "silver leaf" disease of plum trees) that resistance depends on the formation, as a wound response, of a layer of hard gum which mechanically shuts off the parasite.

No reliable evidence exists as yet of any formation of aptitudes such as play a fundamental part in the arrest of certain animal diseases. Here we meet with another illustration of the essential difference between plant and animal diseases.

ECONOMIC IMPORTANCE OF PLANT DISEASES

The number of known plant diseases is very great, and even if those occurring on non-economic plants are ignored, there is still a large residue. A glance at the disease lists of economic crops, such as are published from time to time by departments of agriculture and other bodies, will show as many as 20 or more diseases occurring on particular species of cultivated plants. The majority of these appear, for the present at any rate, to be of little economic importance, but one may say generally that more or less all cultivated plants are subject to two or three diseases of major importance, which at various times or places interfere seriously with their profitable cultivation. Thus in the case of the potato, one may cite four important diseases, blight, wart, common scab and virus disease, all of which afford serious problems to the grower. Of the many diseases reported on the apple, one may mention mildew, scab, canker, brown rot, bitter pit and scald as of the greatest economic importance, and so on, for other crop plants. In any one year and in a given locality, certain of these diseases may do little damage or may even appear to be absent, but over a wide area and over a period of years the aggregate loss is very great. One might forecast that the seriousness of the losses due to plant disease will tend to become greater as the gradual increase in the world's population makes it less possible for the supply of any product to outstrip the demand.

Though the farming class as a whole may in certain cases reap an advantage from the prevalence of plant disease, to the individual farmer the occurrence of disease in his crops can only bring loss. He therefore adopts certain measures with a view to protecting his crops and submits to various legislative restrictions, the object of which is to prevent or limit the spread of plant diseases. All these measures have as their ultimate result an increased cost of production of the article concerned, and this in the long run represents a loss to the community.

Epidemics.—It is, however, when plant disease comes on in epidemic form that the most striking damage is produced. The general public which is unaware of the widespread and ever-continuous frittering away of plant products as a result of disease, sees then the disease in its most concentrated form. Such epidemics have at one time or other produced enormous losses. They have profoundly influenced the economic development of certain countries, and have led frequently to acute distress and famine. The following examples will serve to illustrate these statements.

The rust diseases of cereals are present in all cereal-producing countries and the annual loss in many of them runs into millions of dollars. The estimated loss from the stem-rust disease of wheat in 13 of the northern United States for the ten-year period 1915-24 is given as about \$550,000,000, half of which loss was incurred in a single "rust" year, 1916. The rust epidemic of 1891 cost Prussia about three-quarters of the whole cereal crop. Similar disasters have occurred in India, Australia, South Africa and other wheat-growing countries. It is partly owing to the fact that wheat is cultivated in so many widely separated countries—in all of which a rust epidemic is not liable to occur in any one year—which acts as a safeguard against a serious bread famine.

The coffee disease, also caused by a rust, is a striking example of the effect which a disease may have on the economic history of a country. In the earlier part of the second half of the 19th century, the coffee industry was the mainstay of the prosperity of Ceylon. About 1870 a hitherto unrecorded leaf disease appeared on the coffee bushes. As with many important plant parasites, the seriousness of this disease was not recognized at first. Within a few years the fungus had spread over the whole island and the coffee industry soon disappeared from Ceylon.

Perhaps the most outstanding instance of distress caused by a fungal disease is afforded by the great Irish potato famine in 1845 and 1846. The potato disease ("blight") had only appeared in Europe a few years previously, the causal fungus being, like the potato itself, a native of South America. The disease spread like wildfire over western Europe and in the seasons 1845 and 1846 almost completely destroyed the potato crop in Ireland. As the potato at that time constituted the staple food of the

peasant population, the result of the epidemic was a famine of unprecedented severity.

The story of the coffee leaf disease in Ceylon has in recent years found a very close parallel in that of the chestnut blight in the United States. This disease first appeared in 1904 on a few trees in the neighbourhood of New York. Subsequent investigation showed that the causal fungus was a native of Eastern Asia where it occurs on certain native species of chestnut, but without causing appreciable damage. It had apparently been introduced into the United States on a consignment of chestnuts from the east, and there is every probability that if its importance had been recognized, the disease could have been stamped out in the early stages. As it was, the disease began to spread over the New England states and it soon became apparent that the fungus was more destructive to the American sweet chestnut (*Castanea dentata*) than to the Asiatic forms. Control methods of the most elaborate nature were put in operation, but too late to be effective. At the present time, this disease has destroyed practically all the native chestnuts in the United States. (See CHESTNUT.)

Records of the complete extermination of an industry by fungal disease are fortunately not numerous. On the other hand it would be possible to multiply examples in which fungal diseases are an ever-present menace to particular cultivations. The most important single factor in the cultivation of many economic plants is the liability to certain fungal diseases.

METHODS OF CONTROLLING PLANT DISEASE

The checking of a plant disease, so that if not actually eliminated it is reduced to manageable proportions, is spoken of as its "control." This may be complete or partial. The methods of control may be divided into two main groups, first those which are put into practice by the grower himself, and second those which are enforced upon him by legislation. In the following discussion these will be considered separately.

Voluntary Control.—The adoption of control measures by the grower is subject to a number of severe restrictions. It is only with a certain number of crops that individual treatment of plants is possible, and in all but exceptional cases the economic consideration of cost is all-important. It is idle for the plant pathologist to suggest measures of control if the requirements of time and labour involved in the treatment are such as cannot be satisfied or if the ultimate gain to the grower is not obviously greater than the cost of the measures adopted. The control methods adopted may be directed to increasing the resistance of the plant to disease, or in the case of a parasitic disease may also be directed against the parasite. The former will be dealt with first.

Resistance.—For every plant there is a certain range of environmental conditions within which it grows best. If the conditions vary widely in any important respect from those which are ideal, the plant grows badly. A weakly growing plant is in general more susceptible to parasitic attack than is a strongly growing one, and the abnormal condition of the plant resulting from the unfavourable environment may in itself be so pronounced as to be called diseased. Good cultivation, therefore, which aims at giving the plant the optimal conditions for its growth, is the first line of treatment to be adopted with a view to lessening the incidence of disease.

The most approved methods of husbandry will not however guarantee freedom from plant diseases, nor are they always practicable. More special methods must therefore be adopted. In recent years it has become increasingly recognized that the main line of defense against many important diseases consists in the development of *immune* or *resistant* varieties of the host plant.

To obtain varieties of a crop plant which are resistant to a particular disease is in many cases not difficult. These may in fact exist among the varieties already in cultivation. If the resistant forms possess high merits in other respects—e.g., in yielding power, in quality of product, etc.—then the problem of the particular disease is in large measure solved. Often, however, the

resistant varieties which are already known to occur show certain disadvantageous features, and these may be so great as to outweigh the benefits conferred by the high disease resistance shown.

One method of obtaining a resistant *strain* from a commercial variety consists in growing the plants under conditions in which they are exposed to infection and selecting out for propagation those individuals which stand up successfully against the disease. This method has been adopted with great success in the development of strains resistant to some of the important wilt diseases (cotton, cabbage, etc.).

A more elaborate method consists in the artificial crossing of parents of known characteristics, followed by the sorting out of the different types which occur among the progeny (See PLANT BREEDING.) This is the application to problems of disease of the principles of Mendelism (*qv*). Resistance to disease behaves as a single or multiple Mendelian factor, and is usually dominant in the immediate offspring.

Destruction of the Parasite.—The control of plant diseases by the adoption of measures against the fungus is best considered with reference to the life-history of the fungus and in particular to the manner in which it reinfects the growing crop after each period of winter dormancy.

If the fungus is a *soil parasite*, it may be possible to starve it out by ensuring that it does not come in contact with the particular crops on which it grows and multiplies. This involves a system of *rotation* of crops. The practice of crop rotation is justified for other agricultural reasons and is of great value in that it tends to check the multiplication of specific soil (and other) parasites. Some soil parasites, however, are able to live indefinitely on the humus material of the soil so that they cannot be starved out (e.g., some wilt diseases), others may persist so long in the dormant form that the interval required between successive susceptible crops is too long to be economically practicable (e.g., wart disease of potato).

The elimination of a parasite from the soil by any process of sterilization is generally impracticable on account of the expense involved. In greenhouse cultivation or in those cases where the main source of infection is the seed-bed, soil sterilization may be attempted. For this purpose, heat (e.g., steam-heat as obtained from a boiler) or a fungicidal chemical such as formalin is generally used.

Preventive Measures.—If the disease is carried by the seed, the practical method of control consists either in the selection of seed known to be free from contamination or in some process of seed treatment devised to destroy the parasite without appreciably affecting the germinating capacity of the seed. If the fungus is present merely on the surface of the seed, treatment is generally simple. This consists in steeping the contaminated seed in solutions of various chemicals—formalin, copper sulphate, mercuric chloride, organic salts of mercury, etc.—for a suitable time. The fungus is killed by this treatment whereas the seed is little damaged on account of the protection afforded by its seed coat. Dusting the seed with various chemical powders is similarly effective.

A general palliative measure in the treatment of plant disease is to reduce the amount of infective material available. If the fungus overwinters on the dead remains of the previous year's crop, the latter should be disposed of, either by burning or by digging into the ground. Crop rotation, by segregating to some extent the current year's crop from last year's, is likewise useful.

One of the most important methods of protecting plants against the attack of air-borne parasites is by the use of fungicidal chemicals which are sprayed or dusted over the plants. The object aimed at here is to coat the surface of the plant with a thin but more or less continuous film of the fungicidal substance so that, when the air-borne spores of the parasite arrive, they are unable to initiate attack. Spraying or dusting, if properly carried out, prevents attack but is ineffective if the disease has already established itself. Thus an intimate knowledge of the life-history of the fungus with special reference to the date at which it emerges from its winter resting stage is of the greatest importance for

success in spraying operations. The leaves and young shoots of the plant are readily injured by the action of poisonous chemicals, so that great care is necessary in the preparation and use of fungicides, otherwise greater damage may be done than that which it is intended to prevent. The spray, which consists of a very fine suspension in water of the fungicidal substance, is discharged under pressure in the form of a mist so that as far as possible the whole plant surface is covered. In practice various inert substances ("spreaders") are added in order to facilitate wetting of the leaves and adhesion of the spray. The basis of most sprays in commercial use is either copper or sulphur. To the former class belong the well known Bordeaux and Burgundy mixtures, prepared by adding solutions of copper sulphate to lime and soda respectively. To the latter belong such preparations as "liver of sulphur," "lime sulphur" and "colloidal sulphur."

Legislative Control.—The legislative enforcement of certain measures for the control of plant diseases actually dates back for several hundred years. Witness for example the Rouen act of 1660 for the control of wheat rust by the eradication of barberry bushes (see later). The full development of these measures, however, has only come about within the last twenty years. The Destructive Insects and Pests act was passed by the British parliament in 1907 and a similar law, the National Plant Quarantine act came into force in the United States in 1912. Practically all civilized countries adopted the same type of regulations and at much the same time.

Restriction of Imports.—As between one country and another, the effect of these enactments is to limit free trading in such plants or plant products as are considered likely to bring dangerous parasites into the importing country. The restrictions may amount to a complete embargo, as applies for instance to the import of English potatoes into the United States (on account of the wart disease) or of American gooseberry bushes into England (on account of mildew). In other cases import is allowed provided the material has been inspected by a responsible authority in the exporting country and warranted free from certain diseases. Such material is subjected to further inspection at the port of entry and if found contaminated may be destroyed. From the port it may be liberated directly to the trade or may be sent to a quarantine station, where it is grown in an isolated situation for such time as enables its freedom from disease to be fully established. These restrictive regulations may also be in force between different parts of the same country, as for instance, between the different states of the United States.

Domestic Control Measures.—Within the limits of any one country, legislative control may take the form of compulsory notification of certain diseases. The latter will then be inspected, and the appropriate measures—such as destruction of the infected material—enforced. A further measure is the placing of restrictions on the kind of crop which may be grown within certain infected areas. The legislation against wart disease of potato in England is an illustration of this type of control measure. Within an infected area (called a "scheduled" area) only immune varieties of potatoes may be grown. The enforcement of this kind of measure is very difficult unless suitable immune varieties or other substitute crops are available.

Legislative control of the type outlined above has naturally led to the creation of an inspection service, and further to a wide extension of facilities for advisory work and for the carrying out of research. This increased interest in problems of plant disease, arising from government intervention, is perhaps the most striking development in plant pathology which the 20th century has produced.

CLASSIFICATION OF PLANT DISEASES AND SPECIAL ACCOUNT

In the present section a brief account will be given of some of the more important plant diseases and under the following headings—

- (a) Physiological Plant Diseases
- (b) Plant Diseases due to Bacteria

- (c) Plant Diseases due to Viruses
- (d) Plant Diseases due to Fungi and Slime Moulds
- (e) Plant Diseases due to Higher Plants

Physiological Plant Diseases.—Plants, like animals, may show deficiency diseases due to the lack of some important chemical constituent in their food supply. Thus a lack of iron salts in the soil produces the condition called "chlorosis," in which the green pigment of the plant, chlorophyll, fails to develop. Lack of potash, such as often occurs in poorly manured soils or in light soils leached by heavy rainfall, produces very characteristic symptoms of disease in certain plants, e.g., potato, tobacco and cereals. Similarly, for other essential food elements such as magnesium, phosphate and nitrogen. Conversely, disease conditions may result from the presence of an excess of certain chemicals in the soil. To this class belong various kinds of chlorosis, due to excess of lime or manganese in the soil. The most important diseases of this type are those associated with the accumulation of soil alkali. These are met with in irrigated regions where they often constitute the chief agricultural problem.

Among diseases due to unsuitable environmental conditions may be cited those caused by too high temperature, such as scorch of leaves, heat cancer, etc. The effects of too low temperature are familiar as frost injury to leaves, young shoots, fruit, etc., but a more important illustration is seen in the winter killing of trees in those countries which experience severe winter freezing. The development of "winter-hardy" varieties of cultivated plants is of great importance in countries possessing the continental type of climate.

Injuries due to noxious chemicals in the air are well shown by plants growing in industrial areas. The more important chemicals in this connection are gases, such as coal gas and sulphur dioxide, fumes such as sulphuric acid, and dusts such as soot and cement dust. The latter act by choking up the breathing pores of the plants, but this action is often accompanied by the poisonous effects of gases associated with the dust. In this connection should also be mentioned the injuries which arise from the injudicious use of chemical protective agents such as sprays.

Plant Diseases Due to Bacteria.—The most important diseases of this type are the fire blight (*Bacillus amylovorus*) of apples, pears and similar fruits; the angular leaf spot or black-arm disease of cotton (*Pseudomonas malvacearum*); the olive tubercle (*P. Savastanoi*); citrus canker (*P. citri*); various wilt diseases (*Bacillus tracheiphilus* in cucurbits, *B. solanacearum* in tomato, potato, etc.), soft rots of a number of vegetables (*B. carotovorus* and allied species), two leaf spot diseases of tobacco (*Bacterium angulatum* and *B. tabaci*), and crown gall (*P. tumefaciens*) on a large variety of herbaceous and woody plants.

Plant Diseases Due to Viruses.—This important group was formerly placed among the physiological diseases, but it is now known that they are of infectious or contagious nature. Detailed investigation has failed to show the presence of a visible parasite, but in other respects the resemblance to the parasitic type of disease is very close. The disease can in many cases be transmitted by the inoculation of the juice of a diseased plant into a healthy one. Where this simple method of transmission fails, infection of a healthy plant can be obtained by grafting on it a shoot of a diseased plant. In certain cases it has been proved that the juice of a diseased plant is able to convey infection after it has been filtered through a porcelain cup, whence the current view with regard to these diseases is that they are caused by filter-passing organisms. The symptoms of virus disease are confined to the shoot portions of the plant, and take the form typically of mottling ("mosaic") of the leaves, with as a rule a certain amount of puckering, distortion or rolling. The habit of growth may also be affected, and often there is dwarfing, premature death, and a marked diminution in the yield. The chief agents of transmission are various leaf-biting or leaf-sucking insects, particularly aphides. The number of crop plants which are known to show virus diseases is very large and includes potato, tomato, tobacco, cucumber, clovers, spinach, hop, sugar cane, sugar beet, peach and many others. Certain kinds of ornamental variegation are also infectious and are thus not dis-

tinguishable from virus disease

Diseases Due to Fungi and Slime Moulds.—These constitute by far the most numerous group of plant diseases. The species of fungi which cause plant disease are to be numbered by thousands and occur in all the main divisions into which fungi are classified (see FUNGI). In the majority of text books on plant pathology, these diseases are classified according to the systematic relationship of the causal fungus, but in some cases a grouping according to the crop plant affected or according to the type of symptom produced may offer certain advantages. In the present article, any systematic review of even the more important diseases is impossible. All that can be attempted is to indicate some of the more important groups or types.

The slime moulds (*Myxomycetes*) live mainly on decaying vegetable matter and are responsible for but few diseases of economic importance. A few species have been recorded as causing injury to growing crops, but a definite parasitic relation is doubtful. The group of the Lower Fungi (*Phycomycetes*) includes two subclasses, the *Oomycetes* and the *Zygomycetes*. The former includes the chytrids, the water moulds and the phythiaceae fungi, white rusts and downy mildews, the latter the black moulds and related forms. The best-known example of the chytrids is the finger-and-toe or club root of crucifers (turnips, swede, cabbage, etc.) due to the organism *Plasmodiophora brassicae*. This disease is remarkable for large size of the hypertrophies produced on the roots of affected plants. Another important member of the chytrids is *Synchytrium endobioticum*, the cause of black scab or wart disease of the potato. The downy mildews cause important diseases of a great number of crops including grape, hops, lettuce, several grasses and many others. The late blight and rot (*Phytophthora infestans*) of the potato is perhaps the most important disease of all.

Within the group of the *Ascomycetes* there are numerous important parasites. Species of *Sclerotinia* produce the brown-rot or "mummy" diseases of apple, plum and similar fruits, being among the most destructive orchard parasites. The family of the *Erysiphaceae* comprises the powdery mildews. These fungi cause the abundant formation on the plant of a powdery mass of summer spores, whence the name of the group. Crops of economic importance which are attacked by powdery mildews include cereals, clover, vine, hop, gooseberry, strawberry, apple, rose and oak. Species of *Erysiphe* produce the leaf-curl disease of peaches and almonds and a number of interesting if economically unimportant diseases such as witches' brooms on cherry and birch. To the group of *Ascomycetes* also belong such important diseases as ergot of grasses (*Claviceps purpurea*), apple canker (*Nectria galligena*), wheat scab (*Gibberella saubnetii*), black knot of plum (*Plowrightia morbosa*), chestnut blight (*Endothia parasitica*), and apple scab (*Venturia inaequalis*).

The group *Basidiomycetes* includes three orders of parasites of great economic importance. smuts, rusts and bracket fungi.

The smuts (*Ustilaginales*) are a peculiar group of parasites which live almost wholly within the host plant and usually attack the developing flower and fruit. The latter in the typical case becomes a black powdery mass of spores which constitute the "smutted" head characteristic of this type of disease. The most important examples are found among the grasses—viz., the loose and covered smuts of barley, wheat, oats, rye, rice, maize, etc.

The rusts (*Uredinales*) include perhaps the most important of all plant parasites. The cereal rusts (*Puccinia graminis* and allied forms) are the best known and economically the most serious, but important parasites occur on apple, plum, coffee, Weymouth pine, and many others, especially herbaceous plants. A striking feature in the life history of some of these rusts is that they pass from one host species to another. Thus some forms of the wheat rust parasite have a stage on the barberry; the Weymouth pine blister rust passes to various species of currant. The elimination of the so-called "alternate host" offers a means of control for certain of these rusts. Hence the "barberry eradication campaign" which is being actively prosecuted in certain wheat-growing countries.

The bracket fungi (*Polyporales*) are a group which attack living trees and timber. These are generally wound parasites

which gain entrance through broken branches or other injuries, destroy the wood of the tree, and from time to time produce the well-known bracket-like fructifications on the surface. Species of *Polyporus* and *Fomes* attack a large variety of growing trees.

Diseases due to Imperfect Fungi make up an enormous and miscellaneous list, including such as the following many fruit rots (*Botrytis*, *Penicillium*), wilts (*Fusarium*), stripe disease of cereals (*Helminthosporium*), and an almost infinite number of leaf, stem and fruit spots (*Phoma*, *Septoria*, *Gloeosporium*, etc.).

'Diseases Due to Higher Plants.—Parasites of this type are of great botanical interest, but as a rule of little economic importance. Well known examples are the mistletoe (which is a semi-parasite only, being able to manufacture its carbonaceous food from the air by means of its green leaves) and the dodders or love vines. These attach themselves to and parasitize the stems of other plants.

BIBLIOGRAPHY.—F. D. Heald, *Manual of Plant Diseases* (New York and London, 1926), gives a full bibliography (pp. 20-24) of general and specialized text-books. Current literature *Phytopathology* (American Phytopathological Society, 1911 onwards), *Journal of Agricultural Research* (Washington, D. C., 1913 onwards), *Annals of Applied Biology* (London, 1914 onwards), *Zeitschrift für Pflanzenkrankheiten* (Stuttgart, 1891 onwards), *Review of Applied Mycology* (Kew, England, 1922 onwards). The journal last mentioned gives full abstracts of all the current plant pathological literature. (W. BRO., X.)

PLANUDES, MAXIMUS (c. 1260-1330), Byzantine grammarian and theologian who flourished during the reigns of Michael VIII and Andronicus II Palaeologus, spent the greater part of his life as a monk in Constantinople. On entering the monastery he changed his original name Manuel to Maximus. Possessing a knowledge of Latin remarkable for his time he was sent by Andronicus II in 1327 on an embassy to remonstrate with the Venetians for their attack upon the Genoese settlement in Pera. Planudes, especially by his translations, paved the way for the introduction of the Greek language and literature into the west.

He is the author of a Greek grammar, a biography of Aesop and a prose version of his fables, certain scholia, various original poems. His numerous translations from the Latin included Cicero's *Somnium Scipionis* with the commentary of Macrobius; Caesar's *Gallie War*; Ovid's *Heroides* and *Metamorphoses*; Boetius, *De consolatore philosophiae*; Augustine, *De trinitate*. He also edited a supplement to the Anthology known as *Planudis Planodia*.

See Fabricius, *Bibliotheca graeca*, ed. Harles, xi, 682; theological writings in Migne, *Patrologia graeca*, cxlvi, correspondence, ed. M. Treu (1890), with a valuable commentary, K. Krumbacher, *Geschichte der byzantinischen Literatur* (1897); J. E. Sandys, *Hist. of Class. Schol.* (1906), vol. I.

PLAQUE, a small flat plate or tablet, applied particularly to rectangular or circular ornamental plates or tablets of bronze, silver, lead or other metal, or of porcelain or ivory. Small plaques, called plaquettes, in low relief in bronze or lead, were produced in great perfection in Italy at the end of the 15th and beginning of the 16th centuries, and were usually copies of ancient engraved gems, earlier goldsmith work and the like.

PLAQUEMINE, a city of southeastern Louisiana, U. S., located on the Mississippi river 14 mi. S.W. of Baton Rouge. It is the parish seat of Iberville parish. Pop. (1950) 5,747, (1940) 5,049 by federal census. Plaquemine is served by the Texas and Pacific and Missouri Pacific railways and by state highways 30 and 168. Its principal industries include sugar, lumber, cattle and oil. The town's chief importance, however, derives from the fact that it is the site of the Plaquemine locks, constructed in 1909. The locks are located in a channel which connects the Mississippi river with the Intracoastal canal which extends south and then east and west to Pensacola, Fla., and to Brownsville, Tex.

Plaquemine took its name from the bayou which flows out of the Mississippi river through the Plaquemine locks. The word is said to be a derivation of the Indian word for persimmon, a fruit which thrives in the vicinity.

Plaquemine was incorporated in 1838 and became the parish seat four years later.

PLASKETT, JOHN STANLEY (1865-1941), Canadian astronomer, was born Nov. 17, 1865, near Woodstock, Ont. He

was educated at the University of Toronto, from which he graduated in 1899, and afterwards taught there as an assistant in physics until 1903, when he became associated with the astronomical branch of the Canadian department of the interior. Two years later he was made astronomer of the Dominion observatory at Ottawa, and remained in that position until 1917, when he was placed in charge of the Dominion Astrophysical observatory in Victoria, B.C. After his retirement in 1935, he supervised the grinding and polishing of the 32-in. mirror for the telescope of the MacDonald observatory in Texas.

Plaskett was one of the most noted astronomers of his time. Of his many important discoveries, one of the first came in 1922 when he found that what had for years been considered a large single star was actually two stars. The stars, although clearly visible to the naked eye, could not be identified as twins until Plaskett studied them through the Dominion observatory's 72-in. telescope, which he had been instrumental in persuading the government to install. The stars were subsequently given his name and are known as "Plaskett's twins." He also made valuable studies on the motions of stars, on the Milky Way and its movements and on the rotation of the galaxy.

Of his numerous papers, the most important include *Star Image in Spectroscopic Work*; *Design of Spectroscopes*; *The Rotation of the Galaxy*; *Diffuse Matter in Interstellar Space*, and several on the O-type stars. He was the recipient of a number of honorary degrees and awards for his distinguished services to astronomy. He died at Esquimaux, B.C., Oct. 17, 1941.

PLASSEY, or **PALASI**, a village of Bengal, scene of Robert Clive's victory on June 23, 1757, over the forces of the nawab Suraj-ud-Dowlah. Clive, with a force of about 3,000 men and 8 fieldpieces, took the field against the nawab, who had about 60,000 men, 53 heavy guns and some French artillery under St. Fris. Only the river Bhagratu separated Clive's force from the entrenched camp of the enemy, when the English leader, for once undecided, called a council of war. Clive and the majority were against fighting, Maj. Eyre Coote, of the 39th foot, and a few others for action. Coote's soldierly advice powerfully impressed Clive, and after deep consideration he altered his mind and issued orders to cross the river. After a fatiguing march, the force bivouacked in a grove near Plassey early on June 23. The nawab's host came out of its lines and was drawn up in a huge semicircle almost enclosing the little force in the grove, and St. Fris's gunners on the right wing opened fire. Clive replied and was soon subjected to the converging fire of 50 heavy guns. For hours the unequal fight was maintained, until a rainstorm stopped it. The English covered up their guns, but the enemy took no such precaution.

Mir Mudin, the only loyal general of the nawab's army, thinking that Clive's guns were as useless as his own, made a disastrous cavalry charge upon them, he lost his own life, and his colleagues then had the game in their hands. Mir Jafar persuaded the nawab to retire into the entrenchments. St. Fris stood fast until one of Clive's officers, Maj. John Kalpatrick, successfully drove him in. Clive followed up this success by cannonading the camp at close range.

But the rank and file of the native army, ignorant of the treachery of their leaders, made a furious sortie. For a time Clive was hard pressed, but his cool generalship held its own against the undisciplined valour of the enemy, and, noticing that Mir Jafar's division in his rear made no move against him, he led his troops straight against the works.

After a short resistance, made chiefly by St. Fris, the whole camp fell to Clive's hands. Mir Jafar fled, and was killed. The nawab was captured and died in prison. The British then entered Calcutta and the British rule in India was established.

PLASTER OF PARIS (Gypsum Plaster) $\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$, hemihydrate of calcium sulphate made by heating gypsum $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$. When mixed with water it sets to a hard, white mass, and is used for making casts, and for building purposes.

PLASTER-WORK. Plastering is one of the most ancient of handicrafts employed in connection with building operations, the earliest evidence showing that the dwellings of primitive man were erected in a simple fashion with sticks and plastered with mud. Soon a more lasting and slightly material was employed to take the place of mud or slime, and that perfection in the compounding of plastering materials was approached at a very remote period is proved by the fact that some of the earliest plastering which has remained undisturbed excels in its scientific composition that which is used at the present day. The pyramids in Egypt contain plaster-work executed at least 4,000 years ago (probably much earlier) and yet existing, hard and durable. Indeed the principal tools of the plasterer of that time were practically identical in design, shape and purpose with those used to-day. For their finest work the Egyptians used a plaster made from calcined gypsum just like the plaster of pans of the present time, and their methods of plastering on reeds resemble in every way our "lath, plaster, float and set" work. Hair was introduced to strengthen the "stuff," and the whole finished somewhat under an inch thick.

Very early in the history of Greek architecture we find (e.g., at Mycenae) the use of plaster of a fine white lime stucco. The art had reached perfection in Greece more than five centuries before Christ, and plaster was frequently used to cover temples externally and internally, in some cases even where the building was of marble. It formed a splendid ground for decorative painting, which at this period of Grecian history had reached a very high degree of beauty. The temple of Apollo at Bassae, built of yellow sandstone about 470 B.C., is an excellent example. Pavements of thick, hard plaster, stained with various pigments, were commonly laid in Greek temples. In England the walls of large houses were formerly plastered above the wainscoting and coloured, while the ornamented plaster ceilings of the time of Henry VIII, Elizabeth and James I., are still the admiration of lovers of the art. Still earlier specimens of the plasterer's skill are extant in the pargeled and ornamented fronts of half-timbered houses. With regard to the smaller buildings, comprising small dwelling houses and cottages, the general application of plaster is of comparatively late date; for wainscoted walls and boarded ceilings or naked joists alone are frequently found in houses of not more than a century old both in England and on the continent.

Wood and Metal Lathing.

Lathing is the process of covering a wall or ceiling with a network of thin wooden rods or wires, called laths, which are then plastered over. The laths are usually made of wood, but can also be made of metal. The laths are fixed to the wall or ceiling by means of nails or screws. The lathing is then plastered over in three coats: a rough coat, a brown coat, and a finish coat. The lathing is an essential part of the plastering process, and is used to create a smooth, even surface for the plaster.

joint in bays three or four feet wide with ends butted one against the other. By breaking the joints of the lathing in this way, the lathing is made to act as a single unit, and the plaster can be applied in a single coat. The lathing is then plastered over in three coats: a rough coat, a brown coat, and a finish coat. The lathing is an essential part of the plastering process, and is used to create a smooth, even surface for the plaster.

Lathing of other materials, such as wire, is also used in some cases. This is extensively used on account of its fireproof and lasting quality. There are very many kinds of this material made in different designs under various patents. A lathing has been introduced formed of thin wooden rods wired together at 4-in. intervals. This can be fixed around curves, and economizes plaster.

Lathing nails are usually of iron, cut, wrought or cast—and in the better class of work they are galvanized to prevent rusting. Zinc nails are sometimes used, but are costly.

Materials for Plaster.—The lime principally used for internal plastering is that calcined from chalk or other nearly pure lime-

stone, and is known as fat, pure, chalk or rich lime. Hydraulic limes (see MORTAR IN BUILDING) are also used by the plasterer, chiefly for external work. Perfect slaking of the calcined lime before use is very important as, if used in a partially slaked condition, it will "blow" when in position and blister the work. Lime should therefore be run as soon as the building is begun, and at least three weeks should elapse between the operation of running the lime and its use.

Hair is used in plaster as a binding medium, and gives tenacity to the material. Ox hair, which is sold in three qualities, is the kind usually specified, but horsehair, which is shorter, is sometimes substituted in its stead or mixed with the ox hair in the lower qualities. Good hair should be long, strong and free from grease and dirt, and before use must be well beaten to separate the lumps. In the U.S. goats' hair is frequently used, though it is not so strong as ox hair. The quantity used in good work is one pound of hair to two or three cubic feet of coarse stuff.

Manila hemp fibre has been used as a substitute for hair. As a result of experiments to ascertain its strength as compared with that of other materials, it was found that plaster slabs made with Manila hemp fibre broke at 195 lb., plaster mixed with assal hemp at 150 lb., jute at 145 lb. and goats' hair at 144½ lb. Another test was made in the following manner: Two barrels of mortar were made up of equal proportions of lime and sand, one containing the usual quantity of goats' hair, and the other Manila fibre. After remaining in a dry cellar for nine months the barrels were opened. It was found that the hair had been almost entirely eaten away by the action of the lime, and the mortar consequently broke up and crumbled quite easily. The mortar containing the Manila hemp, on the other hand, showed great cohesion, and required some effort to pull it apart, the hemp fibre being apparently quite uninjured.

Sawdust has been used as a substitute for hair and also instead of sand as an aggregate. It will enable mortar to stand the effects of frost and rough weather. It is useful sometimes for heavy cornices and similar work, as it renders the material light and strong. The sawdust should be used dry.

Some remarks are made on the ordinary sands for building in the article MORTAR IN BUILDING. For fine plasterer's work special sands, not hitherto referred to, are used, such as silver sand, which is used when a light colour and fine texture are required.

In England this fine white sand is procured chiefly from Leighton Buzzard.

External Work.—For external work portland cement is undoubtedly the best material on account of its strength, durability and weather resisting properties. The first coat or rendering is from $\frac{1}{2}$ to $\frac{3}{4}$ in. thick, and is mixed in the proportions of from one part of cement to two of sand to one part to five of sand. The finishing or setting coat is about $\frac{3}{8}$ in. thick, and is worked with a hand float on the surface of the rendering, which must first be well wetted.

Stucco is a term loosely applied to nearly all kinds of external plastering, whether composed of lime or of cement. The principal varieties of stucco are common, rough, trowelled and bastard. Common stucco for external work is usually composed of one part hydraulic lime and three parts sand. The wall should be sufficiently rough to form a key and well wetted to prevent the moisture being absorbed from the plaster. Portland cement is used for all but the commonest external work. White portland cement, made in the United States and France, is very successfully used with white sand to give an excellent stucco closely resembling stone and very durable.

Rough stucco is used to imitate stonework. It is worked with a hand float covered with rough felt, which forms a sand surface on the plaster. Lines are ruled before the stuff is set to represent the joints of stonework. **Trowelled stucco**, the finishing coat of this work, consists of three parts sand to two parts fine stuff. A very fine smooth surface is produced by means of the hand float. **Bastard stucco** is of similar composition, but less labour is expended on it. It is laid on in two coats with a skimming float, scoured off at once and then trowelled. Stucco may be executed in colours, the desired tints being obtained by mixing with the

lime various oxides. Black and grays are obtained by using forge ashes in varying proportions, greens by green enamel, reds by using litharge or red lead and blues by mixing oxide or carbonate of copper with the other materials.

Roughcast or pebble-dash plastering is a rough form of external plastering in much use for country houses. In Scotland it is termed "harling." It is one of the oldest forms of external plastering. In Tudor times it was employed to fill in between the woodwork of half-timbered framing. When well executed with good material this kind of plastering is very durable. Rough-casting is performed by first covering the wall or laths with a coat of well-haired coarse stuff composed either of good hydraulic lime or of portland cement. This layer is well scratched to give a key for the next coat, which is also composed of coarse stuff knocked up to a smooth and uniform consistency. While this coat is still soft, gravel, shingle or other small stones are evenly thrown on with a smooth scoop and then brushed over with thin lime mortar to give a uniform surface. The shingle is often dipped in hot lime paste, well stirred up and used as required.

Sgraffito (Italian for "scratched") is scratched ornament in plaster. Scratched ornament is the oldest form of surface decoration and is much used on the continent, especially in Germany and Italy, in both external and internal situations. Properly treated, the work is durable, beautiful and inexpensive. The process is carried out by applying a first coat or rendering of portland cement and sand, in the proportion of one to three, laid on about $\frac{1}{2}$ in thick, then following with the colour coat, which is sometimes put on in patches of different tints as required for the finished design. When this coat is nearly dry, it is finished with a smooth-skimming, $\frac{1}{8}$ to $\frac{1}{4}$ in thick, of Panan, seletic or other fine cement or lime, only as much as can be finished in one day being laid on. Then by pouncing through the prickered cartoon, the design is transferred to the plastered surface. Broad spaces of background are now exposed by removing the finishing coat, thus revealing the coloured plaster beneath, and following this the outlines of the rest of the design are scratched with an iron knife through the outer skimming to the underlying tinted surface. Sometimes the coats are in three different colours, such as brown for the first, red for the second and white or gray for the final coat. The pigments used for this work include Indian red, Turkey red, Antwerp blue, German blue, umber, ochre, purple brown, bone black or oxide of manganese for black. Combinations of these colours are made to produce any desired tone.

Internal Plastering.—Lime plastering is composed of lime, sand, hair and water in proportions varying according to the nature of the work to be done. In all cases good materials, well mixed and skilfully applied, are essential to a perfect result. When brickwork is to receive plaster, it is all-important that its surface should be rough enough to form a key or, alternatively, that the joints should be well raked out. Plaster is applied in successive coats or layers on walls or lathing, and gains its name from the number of these coats. One coat work is the coarsest and cheapest class of plastering, and is limited to inferior buildings, such as outhouses, where merely a rough coating is required to keep out the weather and draughts. This is described as "render" on brickwork, and "lath and lay" or "lath and plaster one coat" on studding. Two coat work is often used for factories or warehouses and the less important rooms of residences. The first coat is of coarse stuff finished fair with the darby float and scoured. A thin coat of setting stuff is then laid on, and trowelled and brushed smooth. Two coat work is described as "render and set" on walls, and "lath, plaster and set," or "lath, lay and set" on laths. Three coat work is usually specified for all good work. It consists, as its name implies, of three layers of material, and is described as "render, float and set" on walls and "lath, plaster, float and set," or "lath, lay, float and set," on lathwork. This makes a strong, straight, sanitary coating for walls and ceilings. The process for three coat work is as follows: For the first coat a layer of well-haired coarse stuff, about $\frac{1}{2}$ in thick, is put on with the laying trowel. This is termed "pricking up" in London, and in the U.S. "scratch coating." It should be laid on diagonally, each trowelful overlapping the previous one. When on

laths the stuff should be plastic enough to be worked through the spaces between the laths to form a key, yet so firm as not to drop off. The surface while still soft is scratched to give a key for the next coat, which is known as the second or "floating coat," and is $\frac{1}{2}$ to $\frac{3}{4}$ in thick. In Scotland this part of the process is termed "straightening" and in America "browning," and is performed when the first coat is dry, so as to form a straight surface to receive the finishing coat. Four operations are involved in laying the second coat, namely, forming the screeds; filling in the spaces between the screeds, scouring the surface; keying the face for finishing. Wall and ceiling screeds are plumbed and levelled. Screeds are narrow strips of plastering, carefully plumbed and levelled, so as to form a guide upon which the floating rule is run, thus securing a perfectly horizontal or vertical surface, or, in the case of circular work, a uniform curve. The "filling in," or "flanking," consists of laying the spaces between the screeds with coarse stuff, which is brought flush with the level of the screeds with the floating rule.

The "scouring" of the floating coat is of great importance, for it consolidates the material, and, besides hardening it, prevents it from cracking. It is done by the plasterer with a hand float which he applies vigorously with a rapid circular motion, at the same time sprinkling the work with water from a stock brush in the other hand. Any small holes or inequalities are filled up as he proceeds. The whole surface should be uniformly scoured two or three times, with an interval between each operation of from six to twenty-four hours. This process leaves the plaster with a close-grained and fairly smooth surface, offering little or no key to the coat which is to follow. To obtain proper cohesion, however, a roughened face is necessary, and this is obtained by "keying" the surface with a wire brush or nail float, that is, a hand float with the point of a nail sticking through and projecting about $\frac{1}{2}$ in.; sometimes a point is put at each corner of the float. After the floating is finished to the walls and ceiling, the next part of internal plastering is the running of the cornice, followed by the finishing of the ceiling and walls.

The third and final coat is the "setting coat," which should be about $\frac{1}{4}$ in thick. In Scotland it is termed the "finishing," and in America the "hard finish" or "putty coat." Considerable skill is required at this juncture to bring the work to a perfectly true finish, uniform in colour and texture. Setting stuff should not be applied until the floating is quite firm and nearly dry, but it must not be too dry or the moisture will be drawn from the setting stuff.

The coarse stuff applied as the first coat is composed of sand and lime, usually in proportions approximating two to one, with hair mixed into it in quantities of about a pound to two or three cubic feet of mortar. It should be mixed with clean water to such a consistency that a quantity picked up on the point of a trowel holds well together and does not drop. Floating stuff is of finer texture than that used for "pricking up," and is used in a softer state, enabling it to be worked well into the keying of the first coat. A smaller proportion of hair is also used. Fine stuff mixed with sand is used for the setting coat. Fine stuff, or lime putty, is pure lime which has been slaked and then mixed with water to a semifluid consistency, and allowed to stand until it has developed into a soft paste. For use in setting it is mixed with fine washed sand in the ratio of one to three.

For cornices and for setting when the second coat is not allowed time to dry properly, a special compound must be used. This is often "gauged" stuff, composed of three or four parts of lime putty and one part of plaster of paris, mixed up in small quantities immediately before use. The plaster in the material causes it to set rapidly, but if it is present in too large a proportion the work will crack in setting.

The hard cements used for plastering, such as Parian, Keene's and Sirapite, are laid generally in two coats, the first of cement and sand $\frac{1}{4}$ to $\frac{1}{2}$ in. in thickness, the second or setting coat of neat cement about $\frac{1}{4}$ in thick. These and similar cements have gypsum as a base, to which a certain proportion of another substance, such as alum, borax or carbonate of soda, is added, and the whole baked or calcined at a low temperature. The plaster they contain causes them to set quickly with a very hard smooth surface, which

may be painted or papered within a few hours of its being finished.

Mouldings.—Plain, or unenriched, mouldings are formed with a running mould of zinc cut to the required profile. Enrichments to suit a scheme may be added after the main outline moulding is set, being cast in moulds of gelatine or plaster of paris. For a cornice moulding two running rules are usual, one on the wall, the other on the ceiling, upon which the mould is worked to and fro by one workman, while another man roughly lays on the plaster to the shape of the moulding. The mitres at the angles are finished off with joint rules made of sheet steel of various lengths, three or four inches wide, and about $\frac{1}{2}$ in thick, with one end cut to an angle of about 30°. In some cases the steel plate is let into a "stock" or handle of hardwood.

Cracks in plastering may be caused by settlement of the building, and by the use of inferior materials or by bad workmanship, but apart from these causes, and taking the materials and labour as being of the best, cracks may yet ensue by the too fast drying of the work, caused through the laying of plaster on dry walls which suck from the composition the moisture required to enable it to set, by the application of external heat or the heat of the sun, by the laying of a coat upon one which has not properly set, the cracking in this case being caused by unequal contraction, or by the use of too small a proportion of sand.

For partitions and ceilings, plaster slabs (often of fibrous plaster) are in very general use when work has to be finished quickly. For ceilings they require simply to be nailed to the joists, the joints being made with plaster, and the whole finished with a thin setting coat. In some cases, with fireproof floors, for instance, the slabs are hung up with wire hangers so as to allow a space of several inches between the soffit of the concrete floor and the ceiling. For partitions the slabs frequently have the edges tongued and grooved to form a better connection, often, too, they are holed through vertically, so that, when grouted in with semifluid plaster, the whole partition is bound together, as it were, with plaster dowels. Where very great strength is required the work may be reinforced by small iron rods through the slabs. This forms a very strong and rigid partition which is at the same time fire-resisting and of light weight, and when finished measures only from two to four inches thick. The slabs may be obtained either with a keyed surface, which requires finishing with a setting coat when the partition or ceiling is in position, or a smooth finished face, which may be papered or painted immediately the joints have been carefully made. Partitions are formed with one or other of the forms of metal lathing referred to, fixed to iron uprights and plastered on both sides.

Fibrous Plaster.—Fibrous plaster is given by plasterers the suggestive name "stick and rag," and this is a rough description of the material, for it is composed of plaster laid upon a backing of canvas stretched on wood. It is much used for ceilings, partitions, mouldings, circular and enriched casings to columns and girders, and ornamental work, which, being worked in the shop and then nailed or otherwise fixed in position, saves the delay often attendant upon the working of ornament in position.

Desaury, a French modeller, took out in 1856 a patent for "producing architectural mouldings, ornaments and other works of art, with surfaces of plaster," with the aid of plaster, glue, wood, wire and canvas or other woven fabric. The modern use of this material may be said to have started then, but the use of fibrous plaster was known and practised by the Egyptians long before the Christian era; for ancient coffins and mummies still preserved prove that linen stiffened with plaster was used for decorating coffins and making masks. Cennino Cennini, writing in 1437, says that fine linen soaked in glue and plaster and laid on wood was used for forming grounds for painting. Canvas and mortar were in general use in Great Britain up to about 1850. This mortar is also much used for temporary buildings.

It is a notable fact that after World War I the rise of plasterers' wages in Great Britain and the United States, combined with the great scarcity of skilled workmen and other considerations, led to a considerable increase in the use of substitutes for plaster-work.

Various "boards," made of woodpulp and other materials, ply-

wood and asbestos-cement sheets, have come largely into use for the finishing of walls and ceilings.

A later addition to the group of plasters is acoustical plaster. This material, which is heavily sound absorbent when properly worked onto the wall, will reduce objectionable echo. Either acoustical plaster or acoustical wallboard is needed to reduce echo for rooms over 50 ft. in length. Acoustical wallboard is usually considered to be somewhat more effective than acoustical plaster.

(L. C. M. X.)

PLASTICS. The term "plastic," derived from the Greek *πλαστικός*, appears to have been used first as a suffix implying growth, developing and forming. Later it was used as an adjective meaning capable of being formed. The manufacture of pottery and earthenware depends on the plastic qualities of the clay, the making of glass and plastics and the use of putty, asphalt and cement are all dependent upon the plasticity of the product. Properly speaking, all these products should be considered in any description of plastics and the plastics industry, but the term "plastics" is much more highly restricted, although no unchallenged definition can be made of the word. It is used to describe a product of synthetic origin which is capable of being shaped by flow in some stage of manufacture and which is not rubber, wood, leather or metal.

Before the introduction of manufactured plastics, almost any material was pressed into service, especially those materials which could be cut easily and which would take on a high lustre on polishing. Among the products found useful were ivory, coral, tortoise shell, mother-of-pearl, amber, bone and horn. Out of ivory, numerous intricate carvings were made during all periods of history. Ivory lends itself readily to the manufacture of handles for cutlery, for brushes, combs, balls, toys and models. Amber was used in the form of beads and turned into ornaments and holders of various types. Buttons and handles were made out of bone, and combs, handles, drinking cups, powder horns and musical instruments were fabricated out of horn. Although these natural products do not require plasticity in their fabrication, they are consciously or otherwise classed with plastics. The reason that they are so considered may reside in the fact that these natural products may possess a type of residual plasticity or thermoplasticity which enables them to flow slightly from the heat generated during the polishing operation.

While the designation "plastic" is broader generically than the word "resin" (*qv*), both terms are used indiscriminately with respect to synthetic products. It is worthy of note, however, that general usage refers to cellulose derivatives as plastics and not as resins, and conversely, the synthetic resinous products, particularly those entering into the surface-coating field, are referred to as resins and not plastics. Doubtlessly, this distinction is again based on usage, since products of the resin class were primarily employed in the surface-coating field and the plastic characteristics were achieved by solution rather than by heat. The articles called plastics generally require shaping by heat during their fabrication by moulding or extrusion. Since the newer synthetic products can frequently be used interchangeably as coatings or as mouldings, the distinction between resins and plastics becomes less pronounced. Moreover, modern technology shows that the materials which are designated as rubber, fibres, resins and plastics are of a similar molecular structure, and by appropriate chemical and physical treatment it is possible to interconvert any one of these materials. It follows that certain structural features are common to all these products, and, being common, they relate to similarity in physical properties between materials which are not necessarily chemically related.

It might be argued that rubber is a plastic, since it can be fabricated by procedures similar to those employed in moulding plastics, but rubber is not generally considered to be a part of the plastics industry. Moreover, synthetic rubber is in a similar category, even though the preparation of the polymeric rubber molecule employs many of the processes developed for the preparation of resinous polymers. Similarly, the fibre industry is considered to be independent of the plastics industry, and here again the same raw materials, polyamides (nylon), cellulose and cellu-

lose acetate are used by both industries. Plastics are also divorced from the self-supporting type of film production such as the manufacture of photographic film and cellophane. The term plastic, therefore, is essentially a commercial classification to which no strictly scientific definition can be applied.

HISTORY OF DEVELOPMENT

The modern plastics industry is an integration of many different and unrelated bodies of knowledge. One part of the development is derived from the fundamental investigations which were made into the chemistry, physics and biology of such high-molecular-weight natural products as natural resins, rubber, gutta-percha, cotton, cellulose, ramie, pectins, chitin, starch, glycogen, wool, silk and hair. Initially, optical methods were used in order to investigate the nature of these products, and later ultramicroscopy was brought into play. Somewhat later colloidal chemical methods were developed and used in the study of the gross morphology of these substances. X-rays indicated that some of these natural products, such as cellulose, gutta-percha and silk, were crystalline, other materials were amorphous; and still others were both crystalline and amorphous depending on the state of the product. Natural rubber (hevea) in the unstretched state was amorphous when examined by X-ray diffraction methods but it became crystalline when in the stretched state. As new technological tools were developed, they were also brought into use, and among the more powerful of these methods were the measurements of viscosity and the sedimentation of the products when they were subjected to extremely high centrifugal forces such as those developed by the ultracentrifuge. The idea grew that the natural products must of necessity be of a very high molecular weight.

Causes of Resinification.—In the preparation and synthesis of new compounds, materials would often resinsify through unknown and uncontrollable reactions either during the course of the preparation or spontaneously after the product was formed and isolated. Other compounds were made where the transformation to the resinous and polymeric state could be followed and the various stages studied.

J. J. Berzelius in an article in the *Jahresbericht* of 1833 introduced the term "polymer." Naturally the definition which Berzelius presented underwent some later change. Initially, a polymer indicated the presence of the same atoms in the same proportion in compounds having different molecular weight. These conditions satisfy many compounds which are no longer considered polymers. The term "high polymer" is now restricted to high-molecular-weight compounds which are composed of simple molecules while the term "polymerization" (*qv*) relates to the process by which large molecules are synthesized from smaller ones.

In the same year (1833), nitrocellulose was prepared, H. Regnault in 1838 noted that vinyl chloride polymerized in sunlight and in the following year E. Simon polymerized styrene, J. Redtenbacher prepared acrylic acid in 1843, W. Caspary and B. Tollens in 1873 synthesized the methyl, ethyl and allyl esters, whereas G. W. A. Kahlbaum prepared the polymer of methyl acrylate in 1880. It is known that isoprene was prepared by G. Williams in 1860, and that it was polymerized by G. Bouchardat in 1879. R. Anshutz prepared polymers of itaconic-acid esters in 1881, and E. Frankland and B. F. Duppa discovered a method of making ethyl methacrylate from hydroxyisobutyric esters in 1865. Many condensation-type resins were also discovered during this interval, and many polyesters were also prepared, particularly those derived from glycerol and dibasic acids (see RESINS). The transformation of ethylene oxide from monomer to polymer was studied by M. A. von Lourenço, who showed that the boiling point and the viscosity increased progressively with molecular weight of the polymer. I. Ostroimensky maintained that there was a stepwise synthesis of rubberlike substances. Similarly it was observed that when glycine was condensed, there was obtained a series of products in which there was a regular change in the physical properties. The classical work of Emil Fischer in synthesizing numerous polypeptides out of simple amino acids is well known. Although Fischer showed that his synthetic product

possessed many of the properties of the hydrolytic products of naturally occurring proteins, it was generally considered that the natural products such as proteins, cellulose and rubber possessed unique properties of their own and one that was not shared by the products of the laboratory. The so-called "association theory" was advanced to account for the behaviour of the natural products.

Part of the dilemma of the different behaviour shown by natural and synthetic products was resolved by Hermann Staudinger in 1926. He demonstrated the inter-relationship existing between the structure as determined physically by X-rays and the size and structure of the polymer as determined chemically from analysis, as well as the size of the molecule determined by the nature and number of end groups existing in the high-molecular-weight compound. These various ideas were consolidated by Staudinger in his book which has now become a classic, *Die hochmolekularen organischen Verbindungen-Kautschuk und Cellulose*. In this treatise he shows the similarities which exist between polystyrene, a synthetic substance, and rubber (*Kautschuk*) and between the polyoxymethylenes and naturally occurring cellulose. He demonstrated that the products of the laboratory have many properties in common with the natural products and that the synthetic materials can be used as prototypes in evaluating the natural materials.

The causes of resinification of organic compounds remained obscure for a long time. The chemical reactions which led to resinification were unknown and the development was empirical. It was recognized very early that unsaturated compounds yielded resins and when the phenol-formaldehyde resins were first introduced, the same unsaturation hypothesis was advanced. The resin formation of phenol-formaldehyde resins was attributed to the polymerization of methylene quinones. Somewhat later the concept of "resinophoric" groupings (e.g., azomethine—C=N—, carbodiimide —N=C=N—, conjugate unsaturation —CH=CH—CH=CH—, —CH=CH—CHO) was introduced by W. Herzog and I. Kredil, and although the theory was shown to be untenable, it focused attention on the relationship of structure and it led to studies which revealed that there were essentially two chemical reactions responsible for resinification: one involving a condensation reaction, where the polymer differs from the starting material by the elements eliminated in the condensation; and a second involving a polymerization reaction, where the polymer and starting material have the same chemical composition. (See POLYMERIZATION)

About the same time that Staudinger was conducting his investigations in Europe, studies were being made in the United States on various condensation-type resins, and the foundation was laid for the so-called functionality concepts which enabled a clear distinction to be made between the chemistry of the thermoplastic resins and the behaviour of the thermosetting type of product. Synthetic products made by W. H. Carothers using condensation reactions yielded fibrelite materials which possessed many of the crystalline properties which had been associated only with natural products.

In order that a chemical compound can be made to condense to a material of high molecular weight, it is necessary that each molecule of that compound contain two or more functional groups which can react with one another. When a compound contains molecules possessing only one functional group, these molecules on interaction will yield a product which can be, at best, twice as large as the molecules of the starting material. When a compound possesses molecules containing more than two functional groups, then each molecule can be joined to two other molecules. Preferably these functional groups should be at the ends of the molecule or at least so situated sterically that cyclization or intramolecular reaction cannot occur. These important steric or spatial configuration factors were first thoroughly evaluated by Carothers. When all of these requirements are met, it is possible for the functional groups to react with one another intermolecularly, leading to a reaction product containing long chains. These long chains are molecules of high molecular weight. When the product contains molecules having more than two functional groups, the

reaction product which is formed by condensation leads to the formation of complex structures. It is such complex molecules, which are responsible for the industrially valuable physical properties found in plastics.

The functional groups referred to above are simply any chemical groups which can react with others. For example, two organic acid molecules can react to form an anhydride (1, below). If the original starting molecule contains two acid groups and these groups are so situated sterically that ring formation can occur, then ring formation takes place without the formation of a high-molecular-weight compound, for example, succinic acid dehydrates to an anhydride (2). If, on the other hand, the acid groups are situated sufficiently far apart to preclude cyclization, such as are found in sebacic acid, polymers, high-molecular-weight, linear anhydrides are formed (3).

Likewise, an alcohol and acid can react to form an ester. If a simple organic molecule contains an acidic group on one end and an alcoholic group on another, the initial condensation product that is formed still possesses a hydroxyl group and a carboxyl group which can react similarly to the starting materials (4).

Such a condensation can proceed to yield a high-molecular-weight polymer. The unreacted end groups left over at the ends of such large molecules are referred to as "end groups."

A similar situation exists with respect to polymerization products. Under these conditions, cyclization to a low-molecular-weight compound can occur (5); or if the conditions are properly selected, a polymer of high molecular weight may result (6).

Later studies gave some insight into the molecular size and structure of the large molecules that are found in plastic materials. Minor changes during the preparation, and the addition of small amounts of other chemicals, may markedly change both the proportion and the distribution of the molecular species with the result that a new product of differing physical properties may be formed. Moreover, the same materials may under different chemical processing yield resins and polymers of widely different physical characteristics. By means of these two procedures innumerable types of resinous compositions can be produced. Since most of the plastic products depend on the chemical industry as their source of raw materials, it follows that as soon as a new chemical is developed it is immediately tested by plastic manufacturers to determine whether this new material may serve as a partial or a total replacement for the material now employed. The new materials are quickly introduced into the plastics industry, allowing the preparation of new products with different structures and different handling characteristics.

FABRICATING TECHNOLOGY

The development of moulding technology parallels the study of resinification, since it was only by fabricating the synthetic laboratory products that these materials could be turned into articles of commerce. The art of moulding developed following Charles Goodyear's discovery of the vulcanization of rubber about 1839, this involved the use of a simple hand type hydraulic press. This type of press came into use for all types of moulding operations where the mould is sufficiently light to warrant manual handling. With the development of phenolic resins, larger objects could be moulded, and this necessitated the improvement of compression moulding in order to increase the output of any individual mould. Automatic presses were developed and pins were incorporated into the mould itself to permit automatic ejection of the pieces from the mould. Where metallic inserts had to be introduced into the specimen during moulding, semiautomatic presses were constructed, enabling the introduction of inserts in an efficient manner. To eliminate error further and to speed production, automatic presses were fashioned which can measure the charge, pre-heat the charge, load it into the cavity, close the mould, mould the object, open the mould and eject the final piece. Still greater mould efficiencies are achieved by electronic preheating of the plastic prior to its introduction into the mould.

The conventional type of compression moulding is both awkward and expensive when applied to thermoplastic materials. Where compression moulding is used on thermosetting materials the mould can be kept at a uniform and constant temperature. During the moulding and curing operations chemical reaction occurs, causing the plasticity to decrease, with the result that the product is sufficiently rigid while hot to be ejected from the mould. Thermoplastic resins, on the other hand, do not undergo any chemical change, and after fabrication of the piece it is necessary to cool the mould in order to decrease the plasticity to the point where the object can be taken out as a single entity. The idea arose that if it were possible to inject the hot plastic into a cool mould, utilizing the procedure used in the die-casting of metals, it would obviate the periodic heating and cooling of the mould. It is of interest to note that the first experiments directed toward injection moulding were made by John and Isaiah Hyatt, who were also instrumental in first commercializing nitrocellulose (see below), but they abandoned the work. Later the technique of injection moulding was again revived, this time in Germany. The first presses had an injection capacity of from about 0.5 oz to 1.5 oz per cycle and were useful only for the manufacture of small objects such as buttons, combs and costume jewellery. Once the value of these presses was demonstrated and a suitable plastic composition developed, larger and larger presses were designed until it became possible to inject 32 oz of plastic into a mould in a single cycle.

The advent of the injection type of equipment speeded up the production of thermoplastic resins, and in order to increase the mould capacity of the thermosetting resins a type of injection moulding was developed for the thermosetting type of material. This is known as transfer moulding. Since thermosetting resins remain plastic for only a very short time, they cannot be pre-heated in the manner employed for thermoplastic resins; the heating chamber must be loaded afresh for each cycle and the heated charge forced into a hot mould. Not only does transfer moulding decrease the time of moulding of certain objects, but it allows the introduction of inserts which sometimes cannot be introduced into conventional compression mouldings. The plastic enters the mould in a highly fluid state and will not displace or break such fragile inserts as glass and fine metal parts. Moreover, the separation of resin and filler are minimized by this type of moulding, and the resulting moulded objects are stronger, of more uniform density and freer of gas pockets.

A third type of moulding is the so-called extrusion type, which was used for many years in the rubber industry before it was applied to thermoplastic resins. The resin is fed from a hopper, thence to a screw conveyor where the resin is heated, whereupon it emerges from a die in a continuous strip in the form of the die opening. In order to minimize distortion, the heated plastic

is frequently caught on a belt which travels at the same rate as the extruded object. By this means rods and tubing of various sizes and shapes can be produced efficiently.

Still another type of plastic fabrication is the process known as "pulp-preforming." By means of this procedure, resin and filler are deposited on suitable forms prior to moulding.

CELLULOSE PLASTICS

Nitrocellulose.—In 1833 Henri Braconnot, a professor of chemistry at Nancy, described the preparation of a "xyloidine," which he considered similar to lignin, by treating starch, sawdust and cotton with nitric acid. He found that this material was soluble in wood vinegar and attempted to make coatings, films and shaped articles of it. For those who are concerned with origins, it is in these early experiments that one can see the beginnings of both the plastics and the lacquer-coating industry. Somewhat later, in 1846, C. F. Schoenbeni nitrated cotton, using for this purpose a mixture of nitric and sulphuric acids. He also found that he could dissolve the nitrocellulose in a mixture of ether and ethyl alcohol and this solution came to be called "ether glue." At the time, Schoenbeni made the prediction that this nitrated cotton or explosive cotton wool would make a substitute for gunpowder. The explosive nature of this product attracted the attention of militiamen all over Europe, and many governments and private individuals started extensive tests to adapt this smokeless powder to explosive use since, unlike ordinary gunpowder, it left no black smudge after firing. Because crude preparatory methods were employed, disastrous explosions occurred in many countries, with the result that the manufacture of the product began to be looked upon with disfavour.

These explosions had a salutary effect, however, in that the pressure and stimulus were removed from production and allowed leisurely scientific research into processes and means of stabilizing the product.

Investigations into various methods of conducting nitration indicated that several types of nitrated cotton might be made. The nitrocellulose possessing the highest degree of nitration, where the nitrogen content was more than 13%, was referred to as gun cotton or explosive cotton, where the nitrogen content was from 12.6% to 12.8%, the material was referred to as pyrocollodion and where the nitrogen content was from 11.5% to 12% the materials were known as pyroxylon, collodion or photocotton. The nitration reaction is a very complicated one, involving a heterogeneous system of cellulose, nitric and sulphuric acids and water. Each constituent may play several roles which are both physical and chemical in nature, the reagents swelling as well as reacting with the cellulose.

While some attempts had been made to prepare coating compositions out of collodion, the first successful plastic was made by a young U.S. printer, John W. Hyatt. So great was the demand for ivory that the great elephant herds were being slaughtered in an attempt to supply the market. It was in 1863 that Phelan and Collander, manufacturers of ivory billiard balls, offered a \$10,000 reward to anyone who might develop an adequate substitute for natural ivory. Working with his brother, Isaiah, John Hyatt prepared satisfactory billiard balls. Somewhat later the Hyatt brothers were granted a patent which described the process of dissolving nitrocellulose under pressure. Since very volatile liquids were employed as solvents, a great economy of materials resulted. Procedures for mixing the pyroxylon and camphor were disclosed in patents issued to the Hyatts between 1870 and 1872. Subsequently, 75 patents were taken out on various procedures for plasticizing nitrocellulose in order to produce the plastic. In 1870 the Albany Dental Plate Company was organized by Hyatt and in 1871 the Celluloid Manufacturing company was formed. The immediate use of this material was for dental plate blanks, later the plastic was used in sheet form for automobile side curtains as well as the well-known celluloid collars. Toughness, flexibility and good appearance were the properties which enabled the material to be used for a wide variety of items such as combs, brush handles, spectacle frames and various novelty and decorative items.

In 1884 Count Milare de Chardonnet, a pupil of Louis Pasteur, deposited with the French Academy of Sciences a document entitled, "Artificial Textile Material Resembling Silk." The paper, which was opened in 1887, described the method of transforming guncotton into fibrous, silklike material. At the Paris exposition in 1889 he was awarded the grand prize for his discovery. The fibre left much to be desired inasmuch as it was highly inflammable, but it focused attention on the possibility of manufacturing synthetic filaments from a vegetable source.

As noted above, it was possible to dissolve nitrocellulose in ether and alcohol, and such colloid solutions could be cast into films. In the early days of photography, it was necessary to prepare the plate prior to exposure. Many descriptions have been given of the methods employed by the early photographers using their so-called "wet" collodion plates. The solvent combination was extremely volatile, making it difficult to secure uniform films free from "blushing." After the development of the dry-process plate, the next logical step was the elimination of the glass support for the nitrocellulose. Such a nitrocellulose film was demonstrated at a photographic exhibition held in Paris in 1881.

The discovery by John H. Stevens that amyl acetate could be used as a solvent for nitrocellulose was made in 1882. This solvent proved to be far superior to anything used previously and enabled uniform films to be formed without haze. The first successful attempt to secure transparent flexible film for photographic purposes was made by H. Goodwin of Newark, N. J., during the years 1887-98. A somewhat similar process was developed independently by H. Reichenbach in 1889. Further work resulted in processes which allowed the nitrocellulose to be fabricated in continuous fashion, enabling the production of suitable base for both still and motion-picture photography. Another important use for nitrocellulose in sheet form was in safety glass. Sheet nitrocellulose was laminated between glass sheets forming a glass-plastic sandwich. The nitrocellulose film discoloured rapidly, however, and was eventually superseded by other, more light-stable plastics; but it served as an invaluable guide and established the importance of safety glass in the automotive industry.

Prior to World War I, Russia supplied the largest volume of fuel oil. This oil, remaining after the distillation of grain alcohol, was the raw material used in the synthesis of amyl acetate. Following the loss of this source of supply during the Russian Revolution, and with the loss of additional supplies caused by the enactment of the U. S. prohibition laws, the amount of this potential lacquer solvent became vanishingly small. New solvents for nitrocellulose were being developed rapidly, however. During 1920-23 the butyl-alcohol process was perfected by Chaim Weizmann, and about the same time anhydrous ethyl acetate made its appearance. Moreover, other plasticizers than camphor were being developed. Tricresyl phosphate was prepared in 1920 and triacetin in 1921, and both materials weakened the grip of the camphor monopoly which had been notorious in manipulating the price of the product.

Since the theoretical nitrogen content for mono-, di- and trinitrated forms of cellulose are 6.77%, 11.3% and 14.16%, respectively (see Table I), it can readily be seen from the nature of the manufactured products that the most valuable nitrocellulose plastic compositions contain from two to three nitrate groups per glucose residue in the cellulose molecule. Explosives are made

since only thin films can be deposited, and large and excessive amounts of solvent are required. The viscosity of the nitrocellulose can be controlled to some extent by selecting the source of the cellulose and by modifying the nature of the nitration. The most important means of controlling the viscosity of the nitrocellulose, however, is by chemical treatment, and while it had been observed that certain materials such as ammonia and metallic salts had the property of decreasing the viscosity of nitrocellulose, it was found that the most certain method for securing a low-viscosity nitrocellulose was by treating the product with water under pressure.

TABLE I.—Relation between Nitrogen Content and Degree of Nitration of Cellulose

Ester	Formula	% Nitrogen
	$C_6H_7O_5(OH)_2ONOC_2H_5$	6.77
	$C_6H_7O_5(OH)(ONOC_2H_5)_2$	11.30
	$C_6H_7O_5(ONOC_2H_5)_3$	14.16

Several factors contributed to the greatly expanded use of nitrocellulose immediately following World War I. Some idea of the expansion can be seen from the fact that the consumption of these materials jumped from 1,000,000 lb. in 1922 to more than 20,000,000 lb. in 1929. These developments could be traced to (1) the availability of desirable solvents at relatively low cost, (2) to the large quantities of nitrocellulose on hand following termination of the war, (3) the development of a method for preparing lacquers possessing a high solids content with relatively low viscosity, and (4) the tremendous demand for rapid-drying finishes by the rapidly expanding automotive industry. Through the use of a combination of nitrocellulose with alkyd resins, it was possible to decrease the time of finishing of an automobile body from weeks to a matter of hours.

For plastic manufacture, the nitrocellulose or pyroxylin is admixed with alcohol together with camphor, either natural or artificial, and kneaded into a doughlike mass. Colouring matter is added, either in the form of dyes for transparent colours, or as pigments for opaque colours. The coloured masses are rolled to discharge some of the volatile solvent, sheeted and pressed into blocks. After seasoning, the blocks are sliced; then they are either further fabricated, or the process is repeated for various mottled and variegated effects. The sheets may be moulded and when sufficiently soft may be fashioned by "blow moulding" into hollow objects. Rods and tubes are fabricated by extrusion. Artificial leather is made by painting fabrics with nitrocellulose solutions and then stamping or embossing the surface after discharge of the solvent.

Despite its obvious disadvantages of inflammability, discoloration on aging and limited tolerance to heat and to strong organic solvents such as alcohols, ketones and esters, the nitrocellulose plastic is colourful, tough, flexible, of good appearance and resistant to wear, water and humidity. It is easy to fabricate into

For coating applications high-viscosity lacquers are a disadvantage

many diverse forms and finds wide acceptance for billiard balls, piano keys, mirror and spectacle frames, combs, brush handles, machine keys, radio dials and various novelty and decorative items.

The various developments of nitrocellulose in fibres, films, coatings and plastics paved the way for further advances for newer materials which did not possess the disadvantages, enumerated above, and the technology used in nitrocellulose was a useful guide in the processing of new products. Most important, the success of nitrocellulose indicated that a market existed for plastic products.

Cellulose Acetate.—The deficiency inherent in nitrocellulose for plastic use brought up the possibility of adapting other esters of cellulose, particularly the esters of organic acids. Paul Schutzenberger acetylated cellulose in 1865 and A. Franchimont in 1879 found that the esterification reaction could be catalyzed by sulphuric acid. In 1894 C. F. Cross and E. J. Bevan, working in England, patented a process for preparing a chloroform-soluble type of cellulose acetate. The most important commercial development was made by G. W. Miles in 1903-05 with the discovery that if the highly acetylated cellulose was subjected to hydrolysis, it became transformed to a less highly acetylated compound which was soluble in cheap organic solvents such as acetone. In 1911 Henry Dreyfus perfected a manufacturing process for the preparation of the acetylated compound and its hydrolysis. The same basic process is employed in the manufacture of the cellulose acetate as that employed in the manufacture of a nitrate with the exception that the anhydride is used as the esterification reagent with the net result that acetic acid is the by-product rather than water.

The cellulose acetate with an acetate content of about 62.5% is then hydrolyzed, precipitated, washed and dried. This process of hydrolysis can be conducted on the acetate in the fibrous form or in solution. In order to bring out the full toughness of the product, the fibrous acetate is collodized with plasticizers. These are high-boiling liquids possessing a low vapour pressure and having solvent or gelling action on the plastic. Among the more useful plasticizers are such materials as dimethylphthalate, diethylphthalate and dimethoxyethylphthalate. Depending on its ultimate use as a film, moulding powder or safety glass, different quantities, amounts and types of plasticizers are employed, allowing one type of polymer to fill many diverse applications.

The first use for this material was in the so-called "safety film" for photographic use. The acetone-soluble cellulose acetate found extensive use in World War I as the "dope" for coating aircraft wings because it was much less inflammable than nitrocellulose. After the war the excess plant capacity found a ready market for cellulose acetate as an acetate rayon. However, another very important development, the new procedure for moulding thermoplastic resins mentioned above, was occurring simultaneously. It was found that the acetate was particularly amenable to being moulded by injection, and the cellulose-acetate plastic was given a new impetus by this rapid and efficient means of fabrication. The acetate was preferred since the nitrate could not be subjected to the same temperature conditions required in injection moulding. Cellulose acetate became widely used in the automotive industry because of its mechanical strength, toughness, wear-resistance, transparency and ease of mouldability. The high resistance to impact made it a desirable material for protective goggles, tool handles, oil gauges and the like.

Since the cellulose acetate did not discolour as did the nitrate on exposure to light, it was far more suitable for safety-glass manufacture; and, while its resistance to water was not all that could be desired, the laminated safety glass found favour, especially when precautions were taken to edge-seal the assembly in order to prevent access to moisture. Such safety glass became accepted and in time definitely made the public safety conscious.

Cellulose Acetobutyrate and Other Esters.—Since one of the more serious limitations of cellulose acetate lies in its poor

resistance to moisture and weathering, attempts were made to use longer, less water-soluble organic acids for esterification purposes. The use of mixed acids was not overlooked, with the result that it was found that a mixture of butyric and acetic acids (as anhydrides) yielded mixed esters which were very similar in properties to the acetate but possessed much better moisture resistance, better weathering and superior adhesion. When moulded by injection, cellulose acetobutyrate required somewhat less pressure than acetate and yielded better welded joints.

Other cellulose esters were prepared commercially. During World War II processes for the manufacture of propionic acid (and anhydride) were developed, and cellulose esters made from this acid appeared on the market. Since propionic acid contains three carbon atoms, it is intermediate between acetic and butyric acids. It follows that the cellulose propionate possesses many excellent properties similar to those exhibited by the acetobutyrate as well as many characteristics of its own, particularly a shorter moulding cycle and easier machining qualities. Cellulose benzoate was manufactured in Germany but the material did not find a market in the U.S.

Cellulose Ethers.—Since cellulose is a polyhydric alcohol, it can be made to undergo etherification reactions as well as the esterification reactions mentioned above. Ether linkages cannot be saponified, so it is not surprising to find that the cellulose ethers are among the more stable of the cellulose derivatives. The idea of ethylating cellulose was first conceived by W. von Suda in 1905 with the primary object of changing the affinity of cellulose for dyestuffs. The cellulose ethers were studied simultaneously by Leon Lilienfeld in Austria, Otto Leuchs in Germany and Henry Dreyfus in France. It was found that the cellulose ethers and in particular ethyl cellulose were soluble in organic liquids and possessed potentialities in plastic as well as in lacquer and in rayon applications.

Ethyl cellulose was first produced commercially in Germany and it was not until 1935 that large-scale production was undertaken in the U.S. The alkali cellulose—a mixture of cellulose and caustic soda—is reacted with either ethyl chloride or with ethyl sulphate until the desired ethoxy content is secured. While it is possible to introduce three ethoxy groups into each glucose segment in the cellulose molecule, it has been found that only those products which contain from 43.5% to 49.5% ethoxy content are of commercial interest. This degree of ethylation amounts to from 2.15 to 2.58 ethoxy groups per glucose residue. Those ethyl-cellulose derivatives possessing from 47.5% to 50% ethoxy content exhibit the greatest solubility in organic liquids as well as the best compatibility with other film-forming materials. However, ethyl cellulose possessing somewhat lower ethoxy content (from 45.0% to 47.5%) yields harder films and plastics which have less tendency to flow at elevated temperatures. The chief uses of ethyl cellulose are in coating, in adhesives and as plastics possessing a high degree of toughness over a wide temperature range.

Many other cellulose ethers are known. The methyl cellulose, glycol cellulose and cellulose glycolic acid prepared respectively from methyl sulphate (or chloride), from ethylene oxide (or chlorohydrin) and from sodium monochloroacetate are dispersible in water and have found use as sizing and finishing agents in the textile industry.

OTHER NATURAL PRODUCTS AS PLASTIC MATERIALS

Casein Plastics.—Casein (the protein derived from milk) was condensed with formaldehyde by A. Spitteler and W. Kricheldorf to form a tough, insoluble mass which could be fabricated readily. Production of this plastic was begun shortly after 1900 in Germany and France and in 1914 in England under the name of Galalith (milk stone). When the monopoly was broken during World War I, manufacture was undertaken in the U.S. in 1919. At the time the casein plastic came into prominence it possessed an immediate advantage over the competitive products inasmuch as it was much less inflammable than nitrocellulose and could be fabricated into objects of lighter colour than was possible with the phenolic resins. When an attempt was made to introduce the

COMMON SMALLER ARTICLES OF PLASTICS

From left to right, top to bottom: kitchen clock (acetate), fabric (seran), trays (acetate), electric shaver (phenol and urea), small juice extractor (styrene), data stamp (phenol), measuring cup (urea), egg holders (acetate), salad spoon and fork (acetate), strainer (acetate and urea), salt

and pepper shaker (acetate), doorknob (styrene), keyhole flashlight (below salad fork) (urea), fishing tacklebox (to right of salad spoon and fork) (acetate), card box (acetate), strips of extruded moulding (acetate and butyrate), cigarette holder (acrylic), transparent funnel (polystyrene)

casein plastic in the United States, the limitations of the material became apparent, especially under the extremes of humidity encountered. The result was that the product was wholly unsuited for electrical fixtures and other applications requiring some degree of dimensional tolerance. The limitation of the composition, and the advent of synthetic resins which could be handled more rapidly and did not possess the limitations inherent in the protein plastic, gradually restricted the use of casein plastic until the only large outlet for the product was in the manufacture of buttons from alum-hardened casein.

Shellac.—This natural resin finds use in the manufacture of moulding compositions, particularly phonograph recordings. In many respects shellac is an ideal plastic binder for certain types of electrical equipment and communication instruments. The resin is often used by itself as well as in combination with such fillers as flaked mica and asbestos.

SYNTHETIC RESIN PLASTICS

Synthetic resins can be grouped into many different arrangements but one generally accepted classification involves the designation "thermoplastic" and "thermosetting" types of resins. The thermoplastic resins are characterized by their ability to remain plastic after numerous heating treatments, while the thermosetting or thermocuring resins are not susceptible to repeated heating cycles and, once heated, are converted to a cured or infusible form which cannot be fused again without serious chemical degradation. From the molecular structural standpoint, the thermoplastic resins are characterized by molecules which are essentially linear or threadlike in form, while the thermocuring resins consist of molecules which are considered to be linked three-dimensionally into a network arrangement. Resins may also be classified by the chemical means employed to effect reaction. Certain resins formed without the elimination of volatile components are generally referred to as the polymerization type. Where volatile ingredients such as water and alcohol are formed during the resin preparation, this type of product can be considered a condensation resin. When the chemical and physical types are superimposed, it is possible to have the grouping

- 1 Thermoplastic condensation resins
- 2 Thermoplastic polymerization resins
- 3 Thermocuring condensation resins
- 4 Thermocuring polymerization resins

The equations leading to the formation of these various types may be written schematically as follows

Linear polymer formed by condensation reaction

Linear polymer formed by loss of unsaturation

Network polymer formed by condensation reaction

Network polymer formed by loss of unsaturation

Generally the thermocuring resins will tolerate substantial quantities of inert fillers such as cellulose flock, wood flour, asbestos and the like, whereas the thermoplastic resins are fabricated clear or when fillers or opacifiers are used, the quantity employed is much less than with the thermosetting type of resin. Different

methods of fabrication are utilized with thermoplastic and thermosetting resins since chemical changes occur during the moulding of thermocuring resins, whereas physical changes predominate in the moulding and extruding of thermoplastic resins.

Thermosetting Resins.—**Phenol-Formaldehyde Resins.**—When Leo H. Baekeland offered the phenol-formaldehyde resins in 1909, the value of nitrocellulose plastics sold annually in the U.S. was more than \$5,500,000. Irrespective of the fact that the pyroxylin plastic was well established, this new material found a ready market because, unlike the nitrocellulose product, the phenol-formaldehyde resin could be made insoluble and infusible. Moreover, unlike the thermoplastic material, the thermosetting phenolic condensation product would tolerate considerable amounts of inert ingredients or fillers and, in much the same manner that the thermoplastic materials could be changed by the incorporation of various plasticizers, the thermosetting resins could be modified through the incorporation of various fillers.

In some respects, this resin-filler combination was being exploited prior to Baekeland's entrance into the plastic moulding field. Various coal-tar residues were mixed with asbestos and silica and these resins were moulded under pressure and subsequently heated outside the mould to further the reaction. Since a great deal of curing does not occur, the strength of such cold-moulding compositions was not very high. When the phenolic binder became available, however, and when it was substituted for the bituminous binder, the moulded piece took on a much better finish and possessed increased strength.

In making phenolic moulding powders, phenol and formaldehyde are heated in the presence of suitable catalysts, generally acids, and the condensation is conducted to the stage where the water separates. The viscous phenolic condensation product on cooling to room temperature becomes hard and brittle. The resin at this stage is soluble and can be dissolved in various organic liquids; such solutions are employed for laminating and impregnating purposes. The structure can be represented schematically as follows.

In order to make the moulding compound, the resin is ground and mixed with appropriate filler, lubricants and dyes. To render the combination as homogeneous as possible, the mixture is milled and then ground. For general use, wood flour is the preferred filler, but where heat resistance, impact strength or electrical characteristics are involved, other fillers such as cotton flock, asbestos and chopped fabric are used. The resin, because of its excellent insulating characteristics, enters into the manufacture of radio parts such as sockets, binding parts, knobs and dials, and into the electrical system of the automobile in the form of distributor

heads, coil parts, switches, magnetos, instrument-housing panels and the like

Where the resin is to be cast, the initial condensation of the phenol and formaldehyde is heated with alkaline catalysts in such a way as to hold the water which is formed in the condensation as a suspension in the resin. The reaction mixture is subjected to reduced pressure whereby the water of condensation is removed without phase separation. Where opaque castings are desired, the viscous resin is poured directly into moulds made of either rubber or lead. Hardening is allowed to take place from one to two days at moderately elevated temperatures. During curing of the resin, the water which is evolved forms droplets which are large enough to interfere with the transmission of light. Where clear castings are required, suitable modifiers are added to the resin prior to the introduction into the mould. These modifiers cause the water which is formed in the final cure to assume a size smaller than the wave length of light and, being of such dimensions, the particles do not interfere with the transmission of light. Such castings are clear. Mottled effects can be secured by appropriate mixing of coloured viscous resins prior to the introduction into the mould. The castings are machined and polished to objects possessing a high degree of lustre and brilliance.

For laminated structures, the resin in alcoholic solution is used to impregnate either paper or fabric. After impregnation the sheets are dried, consolidated and subsequently heated under pressure to form a rigid, tough assembly of high strength and good electrical properties which can be machined and fabricated. Power transformers, timing gears, cams, clutches, fan belts and many other materials can be made from such structures. When fabric is substituted for the paper, similar laminated compositions are made which can be machined to form gears and bearings.

Lignin, which is the bonding agent of wood and other cellulosic derivatives, has been isolated from certain intermediates from paper manufacturing. The lignin resins have been used as extenders for phenolic resins, particularly those entering into varnishes, moulding resins and adhesives.

Phenol-Furfural Resins—Furfural is an aldehyde which is derived from waste farm products such as the hulls of oats, rice and cottonseed and corn husks. This aldehyde will condense with phenol to produce a resin similar to that secured from phenol and formaldehyde. The plastic properties of the two compositions differ, however, in that the furfural product possesses a long period of flow at low temperatures; this property enables it to be used in certain types of intricate mouldings.

Urea-Formaldehyde Resins—The resins derived from urea and formaldehyde have been considered truly synthetic materials inasmuch as all the basic materials are derived from gases. These gases are ammonia, carbon dioxide, carbon monoxide and hydrogen. Reaction of ammonia and carbon dioxide under pressure yields urea, whereas the reduction of carbon monoxide results in the formation of formaldehyde. Condensation of urea with commercial formalin (aqueous solution of formaldehyde) yields the water-soluble intermediate condensation products known as mono- and dimethylolurea, which on further reaction form water-soluble, resinous condensation products.

The intermediate water-soluble resins are starting materials for the production of resin, adhesives, surface coatings and moulding powders. Initially, glass-clear products were produced and extensively investigated as substitutes for glass and were often referred to as "organic glass." While the initial products were clear and brilliant, they quickly deteriorated on aging. Part of the difficulty resided in the ability of the plastic to absorb water from a humid atmosphere and then to release the water when the moisture content of the atmosphere decreased. This "breathing" of the plastic resulted in some loss of transparency and glasslike clarity. Furthermore, on prolonged standing, cracks and fissures developed in the surface of the resin, probably arising from liberation of water and formaldehyde through further condensation occurring in the colloidal mass; these fissures further decreased the transparency and limited the strength of the product since, on impact, the surface fracture acted as a focal point for the transmission of energy into the interior of the specimen. The glasslike

product was extensively investigated by Harlan John and by Heiner Ramstetter and by Fritz Pollak and Kurt Ripper during

the decade following World War I, but attempts to commercialize the product were unsuccessful.

The combination of the urea-formaldehyde resin with various fillers was investigated by many chemists, but the combination of cellulose and resin has been generally associated with the development work of Carleton Ellis in the U.S. A parallel development occurred in England, however, where because of lack of timber, Norwegian pulp was imported and used. The introduction of fillers destroyed the transparency of the product but the resin-filler combination, when suitably compounded with flow promoters, plasticizers, lubricants, accelerators and catalysts, could then be moulded in steel dies under heat and pressure to insoluble and infusible products possessing a wide utility. Manufacture of one of these materials began in the U.S. in 1929. The plastic can be produced in any colour, from translucent and colourless to ivory and pure white, through pastels and brilliant hues to jet black. In thin sections the natural uncoloured combination of urea and cellulose transmits light in a highly diffused state, and by altering the thickness and pigmentation, the reflection and transmission can be modified at will. Among the widespread uses of the moulded product, aside from its value in luminaires, are in the manufacture of closures, buttons, wall plates, instrument dials, display boxes, dress accessories and housings of all types.

The resin in solution form possesses many other applications aside from impregnating filler to make moulding compositions. The resin solutions are used in the preparation of cements which can be hardened hot or, through the proper addition of catalysts, may be set cold. When the water-soluble resin is suitably dispersed in organic solvents, it forms the basis of a very important class of resin finishes and enamels for metal coating. As an impregnant for wood veneer, the water-soluble condensation products serve both as a binder and a protective coating. Since the resin is colourless, the cured resin materially enhances the beauty of the wood. The solutions are also used to treat textiles in order to control their shrinkage and render them crease or crush resistant.

In the manufacture of laminated stock, sheets of absorbent paper are impregnated, dried and assembled to appropriate thickness and then heated between platens to yield a sheet stock which has found utility in lighting reflectors, signs, wall panels, table tops and decorative murals.

Melamine-Formaldehyde Resins—Prior to 1939 melamine was practically an unobtainable rare chemical compound which could be secured only in limited amounts at \$40 a pound. Although the compound was rare, it was not new and unknown. It had been known and characterized for more than 100 years and had been first prepared in 1834 by the famous chemist Justus von Liebig.

After 1939, melamine became a commercial article made in ton quantities, and like urea it is secured from the air. Combination of the nitrogen in the air with calcium carbide yields calcium cyanamide, which can be hydrolyzed to cyanamide and dimerized to dicyandiamide. Under high temperature and pressure dicyandiamide is transformed to melamine, an extremely stable substance containing only carbon, hydrogen and nitrogen in its chemical structure. These reactions can be represented by the following chemical equations

Preparation of melamine from calcium cyanamide

Condensed with formaldehyde, melamine forms products which in superficial respects resemble the condensation products of urea but, where only mono- and dimethylolureas have been prepared, a much wider number of the initial melamine-formaldehyde condensation products are known. Di-, tri- and hexamethylol melamines have been prepared

Melamine formaldehyde

Trimethylol melamine

Network condensation of melamine with formaldehyde

The melamine resin is not so sensitive to alkalis and can tolerate fillers which cannot be used with the urea condensation product. One of these fillers is the mineral asbestos. Because of their excellent heat and arc resistance, good dielectric strength and low water pickup, mineral-filled melamines suitably modified with other resins were used in ignition systems, particularly in the large distributor heads in military aircraft where, under the reduced pressures at high altitude, flash-over and tracking are especially troublesome. The mineral-filled materials may also be used where other unusual performance characteristics are required such as in the automotive ignition parts of trucks, tractors and automobiles.

Cellulose-filled melamine plastics have been used in many of the applications already discussed for the urea resins, but since the melamine resin is more resistant to high temperatures, to boiling water and to more alkaline solutions, and since it does not retain food odours, it is particularly useful in tableware. The melamine resin possesses extreme hardness and thus, together with its good colour and abrasion resistance, makes it an invaluable material for surfacing of laminated assemblies. Transparent mouldings may be made and are applied to button manufacture.

Anhydrous Thermosetting Resins.—The thermosetting resins used for laminating and moulding depend on the loss of water to

effect insolubilization. In order that this water content be as small as possible, the resin is carried to an advanced stage of condensation where considerable heat and pressure must be utilized to cause the resin to flow sufficiently to fill the mould. During World War II, new types of products appeared which did not involve the loss of water to bring about insolubility and infusibility of the resin. These compositions have been referred to as anhydrous thermosetting resins and solventless varnishes, while the process has been called low-pressure or contact moulding. They belong to the class of thermocuring polymerization type of resins. Irrespective of the name, all of these resins have one characteristic in common: the polymerizable molecules possess a plurality of unsaturated groups and undergo reaction to insolubility quickly and exothermically without the evolution of low-molecular-condensation residues. The unsaturation can be introduced into the initial molecule by the incorporation of either unsaturated acid residue or unsaturated alcohol residues or both. The polymerization is generally catalyzed by peroxides. The physical state of the anhydrous thermosetting resins can be varied within wide limits; some are thin fluids, other viscous liquids, whereas still others are solid or grease-like in consistency. Since only low pressure is required in fabrication, comparatively inexpensive moulds can be utilized. In many instances, the fluid-moulding technique may be employed for making complex shapes; this procedure depends on delivering pressure uniformly over a large area through the use of rubber bags, and by such means large structural parts of aeroplanes and boats have been built. When such rigid sheets of plastics are laminated into a cellular or honeycomb core, highly rigid and lightweight combinations can be produced which possess good strength and insulating characteristics.

Thermoplastic Resins.—Vinyl Resins.—As noted above, acetic anhydride is required in the manufacture of cellulose acetate. Following World War I various methods were investigated for processes which might be used to convert the acid to the anhydride since it was anticipated that large quantities of this cellulose plastic would be required in the manufacture of fibre, film and safety glass. Among the methods investigated for the manufacture of acetic anhydride was the reaction of acetic acid with acetylene to form ethylidene diacetate, which in turn could be decomposed to acetic anhydride. In conducting the reaction between acetylene and acetic acid, investigators obtained substantial quantities of an organic liquid which was too low boiling to be the desired product. This liquid was monomeric vinyl acetate. Although the investigation was directed primarily to the preparation of an acetylating agent, vinyl acetate was in time destined to be the basis of the manufacture of most of the plastic for use in safety glass.

Polyvinyl Acetate Resins.—The transformation of vinyl acetate ($\text{CH}_2=\text{CH}-\text{O}-\text{CO}-\text{CH}_3$) to a safety glass interlayer did not occur all at once, however. Manufacture of the early product was difficult because little was known concerning the chemistry of transformation of a vinyl monomer to its polymer. Moreover, the early development was hazardous from a commercial standpoint since there were no uses for such a resinous product. It was first investigated as a shellac substitute, but its remarkable adhesive properties, when hot, made it invaluable for uniting many diverse materials such as cloth, paper, leather, wood and glass. Compounded with fillers, glycerine, sugar and flavouring, polyvinyl acetate makes an acceptable chicle substitute in the manufacture of chewing gum. Hydrolysis of the polyvinyl acetate causes cleavage of the ester grouping resulting in the formation of polyvinyl alcohol.

a resinous polymeric alcohol that forms viscous solutions in water and finds some utility as a thickening agent for emulsions and in the preparation of plastics which, although sensitive to water, are highly resistant to oils. Polyvinyl alcohol can be spun into a fibre, and although the fibre is soluble in water, special uses can be made of this solubility in the weaving of sheer laces, fibres of

polyvinyl alcohol and any other fibre can be woven and the synthetic water-soluble fibre dissolved, leaving a sheer fabric which would be difficult to approach by mechanical means alone.

Many chemical transformations of polyvinyl alcohol are possible. It can be condensed with other low-molecular compounds, particularly aldehydes, to form new resinous materials. Condensation with formaldehyde, acetaldehyde and butyraldehyde results, respectively, in polyvinyl formal, polyvinyl acetal and polyvinyl butyral. The polyvinyl formal finds use as a coating resin for electrical insulation, the acetal possesses potentialities as a photographic film base and as an injection-moulding material, but it is the butyral which possesses the most outstanding utility, and as much as 100,000,000 sq ft has been produced annually for safety-glass manufacture. The resin when suitably plasticized yields a tough, high-impact film which maintains its properties at low temperature, and when laminated between glass yields a composite assembly which possesses little tendency to yield flying splinters on impact.

Polyvinyl Chloride Resins—Vinyl chloride is a gas at room temperature and can readily be prepared from either ethylene or acetylene. Addition of hydrogen chloride directly to acetylene yields the monomer, or ethylene can be chlorinated and dehydrohalogenated to vinyl chloride. The polymerization was extensively studied by Ostromislensky, who sought to dehalogenate the polymer to a rubberlike substance. Polyvinyl chloride was transformed to a rubber substitute about 20 years after these basic investigations but by an entirely different procedure.

Polymeric vinyl chloride, $-(CH_2-CHCl)_n-$, is practically infusible and for a long time proved to be a rather intractable substance. In efforts to plasticize the product it was milled and compounded with polyvinyl acetate, mentioned above, but with no great degree of success until it was found that by mixing the ingredients prior to polymerization and then chemically combining the two materials into a polymeric structure, it was possible to achieve in this conjoint polymer or copolymer a new type of product which was easier to handle and one which could be further flexibilized through the addition of high boiling liquids and plasticizers. By varying the ratio of acetate to chloride, resins of varying plasticity and stiffness can be secured.

Intensive investigations were made into the nature of plasticization methods and techniques of direct plasticization of vinyl chloride without the necessity of copolymerization. It was generally conceded, however, that the copolymer is amenable to plasticization by a larger number of widely diverse liquids than is the unmodified polymer. Both types, however, have found extensive use as sheet stock and as wire insulating compounds and as substitutes and replacements for rubber. Since these polymers possess considerable amounts of chlorine, they will not support combustion and they therefore possess distinct advantages in wiring where nonflammability is of importance. The halogen, however, is labile and when the resin is exposed, to heat or to ultra-violet light, loss of hydrogen halide occurs, resulting in discoloration.

By the dry spinning of the vinyl chloride-acetate copolymer, it is possible to produce filaments which can be woven into chemically resistant fabric. In Germany fibres were fabricated directly from polyvinyl chloride and were known as PC-fibres.

Polyvinylidene Chloride Resins—By doubling the amount of chlorine in vinyl chloride, a new chemical entity, vinylidene chloride, is obtained. Because of the symmetrical arrangement of the chlorine atoms in polyvinylidene chloride, $-(CH_2-CCl_2)_n-$, the polymer is crystalline, and advantage can be taken of this crystalline characteristic to form oriented filaments and tubing. Such oriented forms have the molecules arranged in an ordered manner with the result that in the direction of orientation the product is very strong. Extruded, quenched and drawn, the polyvinylidene chloride makes an excellent substitute for red and rattan and a corrosion-resistant substitute for insect screening; in the form of tubing, the resin can be used to pipe many corrosive chemicals.

Acrylic Resins—The term acrylic resin covers not only the acrylic esters but also the polymerizable derivatives of both acrylic

and methacrylic acids as well as the acid chlorides, nitriles, amides and substituted amides. Acrylic derivatives generally involve cyanide in their synthesis, but investigations indicate that, at least in the case of the acrylic acid derivative, there may be an alternative procedure involving carbon monoxide (in the form of a metallic carbonyl) and acetylene. Considerable investigation was also undertaken in an attempt to prepare acrylic esters from natural lactic acid derived from milk, but it remained to be demonstrated whether the natural lactic acid could compete with the synthetic product. The names of Otto Rohm and Rowland Hill were associated with the preparation and polymerization of acrylic and methacrylic esters, respectively.

From the standpoint of plastic use the methacrylic esters are preferred, since they are harder and more rigid than the corresponding acrylic esters. By changing the type of alcohol which is used in esterification of the original monomeric ester, it is possible to modify the hardness of the resulting polymer. Poly-methyl acrylate is tough and rubbery, polyethyl acrylate is softer and more rubbery, polybutyl acrylate is sticky. If one continues up the homologous series of alcohol esters, the polymers become softer and more plastic until at polyoctyl acrylate, it is found that the polymer is almost liquid in consistency.

ester in the methacrylate series and, as in the case of the acrylates, the introduction of alcohols possessing longer chains into the ester lowers the softening point of the plastic. Some idea of the relative hardness can be seen in the fact that polyvinyl methacrylate is about as hard as polymethyl acrylate. While polymethyl methacrylate is the preferred resin for injection moulding and plastic applications, it was found that cyclohexyl methacrylate was superior for lens casting, since this liquid undergoes less shrinkage during polymerization than does the methyl ester. Cyclohexyl methacrylate polymer, together with styrene resin, was used in combination in the preparation of plastic achromatic lenses.

Without doubt the largest single outlet for the methyl methacrylate resin has been in sheet form for windows in aircraft, particularly in military aircraft. The resin was cast in moulds made of glass and the finished sheet could then be "post-formed" to a wide variety of shapes necessary for blisters, noses, cockpits, windshields and canopies of aircraft. The high clarity of these plastics, as well as the ability to transmit or "pipe" light, also favoured their use in surgical instruments, highway reflectors and edge-lighted advertising displays.

Whereas styrene was copolymerized with butadiene to form a general-purpose rubber, acrylonitrile, the nitrile of acrylic acid ($CH_2=CH-CN$) was copolymerized with butadiene to yield a special oil-resistant rubber extensively used where rubber of necessity had to be in contact with gasoline and other hydrocarbon liquids. Acrylonitrile forms conjoint polymers with many other vinyl compounds such as acrylic esters and styrene, but from all indications it promised to play its most important role as a polymer in the form of a synthetic fibre. **Polyamides**—By the condensation of diamines and dibasic acid, linear condensation products may be formed and by varying the nature of the acid and the amine, it is possible to produce products which are hard and tough or soft and rubbery. These linear condensation products are referred to as polyamides $[-NH-(R)-NH-CO-R'-CO-]_n$. Polyamides are most generally known in the form of fine and coarse filaments in such articles as hosiery, parachutes, bristles and brushes. As has been pointed out, however, high-molecular-weight organic resinous compounds of certain types can be converted into fibres. The polyamides were first offered commercially in the form of filaments but were later directed to the moulding trade, particularly toward the injection-moulding field where their toughness and ability to flow around complicated inserts are prime considerations. Polyamides, particularly those derived from primary amines, are characterized by a high degree of crystallinity whether in the form of filaments or as mouldings. Under stress, orientation of molecules begins to occur and this orientation continues until the specimen is drawn to about four times its initial size, although this property is of outstanding importance in filaments, it is of more limited utility in moulded articles. The resin exhibits a sharp melting point, and on melting is more liquid and plastic than conventional resinous materials. The fluidity is both an advantage and a disadvantage the high fluidity

necessitates the use of specialized equipment but on moulding there is no need of using excessive pressure in injection moulding, since the liquid resin transmits its pressure on the moulded specimen hydrostatically.

A product somewhat similar to the polyamides, manufactured in Germany during World War II, utilized isocyanates, particularly the diisocyanates. Reaction of these unsaturated compounds with glycols yielded polyurethanes $[-NH-R-NH-CO-O-R'-O-]$, which could be fabricated into films.

Polystyrene Resins.—That styrene or vinyl benzene would polymerize has been known for a long time. The designation "vinyl benzene" ($CH_2=CH-C_6H_5$) immediately relates it to the other polymerizable vinyl compounds, such as vinyl chloride, fluoride and acetate. The designation "styrene" arose from the fact that this liquid was first prepared by heating the natural resin storax. The first patents on the possible uses of styrene were taken out by F. E. Matthews in 1912. Monomeric styrene is present in the light oils of coal-tar manufacture and in the drip oils condensed during the preparation of illuminating gas, and although extensive investigations were undertaken to remove styrene from this source, the processes proved too costly and could not compete economically with the synthetic methods. In order to secure a satisfactory plastic out of styrene, it is necessary that a highly purified product be subject to polymerization. Where the monomeric styrene

factor and a low dielectric constant. Being highly symmetrical, it is also crystalline, and in common with other crystalline polymers, thin sheets of the resin exhibit high resistance to penetration by water vapour.

At ordinary temperatures the resin is highly resistant to attack by organic and inorganic reagents. At moderate temperatures, the resin can be dissolved in certain organic liquids and such solutions can be applied as a coating, but satisfactory results are obtained only by keeping the object coated in a heated condition until the solvent has evaporated. Polyethylene, however, can be applied more easily directly by extrusion of the molten plastic. It proved suitable for insulating high-frequency and high-voltage circuits. Because of its low water permeability, extensive tests were carried out with a view of using the resin in submarine cables.

Polyisobutylene Resins.—Isobutylene is a hydrocarbon boiling at about $-5^\circ C$, and when dimerized it can be converted by reduction to iso-octane. By conducting the polymerization at very low temperatures, using boron fluoride as a catalyst, a high-molecular-weight

inasmuch as the material is saturated, it cannot be vulcanized. By conducting the polymerization of isobutylene along with a diene such as butadiene, isoprene or dimethyl butadiene, unsaturated residues are introduced into the polymer. These residues can act as nuclei for vulcanization with sulphur.

Perhalogenated Plastics.—Several references can be found in the patent literature to the preparation of polymeric materials which possess only carbon and halogen in their molecular structure. The

water absorption of the resin is extremely small. The resin can be dissolved in coal tar and in chlorinated solvents. In electrical characteristics, the plastic possesses an extremely low power (or loss) factor and, when the resin is properly prepared, this power factor remains substantially unchanged over a wide range of frequency. The low power factor combined with the low water absorption makes polystyrene an ideal material for various electrical and electronic applications. The presence of a multiplicity of aromatic rings in the polymer renders the product responsive to temperature, with the result that the resin can be handled expeditiously by the injection-moulding technique. Among the noteworthy applications of this plastic is the fabrication of battery boxes, ranging in size from those employed in a small automobile to the type that is ordinarily used in portable radio sets. It has found utility in manufacture of condensers, tube sockets, coil forms and switch plates. Since styrene was one of the components entering into the synthetic rubber GR-S, large facilities exist for the manufacture of the monomer. Some idea of the expansion that took place can be seen from the fact that the amount of polystyrene used rose from about 750,000 lb per month in 1937 to more than 20,000,000 lb per month in 1951. During this period progress was made on the commercial casting of styrene in several forms. As a copolymer with divinyl benzene, the resin was employed for certain radar applications which involved operating temperatures higher than could be tolerated with polystyrene. The monomer was also cast directly for certain optical parts such as prisms and lenses. Since polystyrene possesses a high dispersion value, it could be combined with polycyclohexylmethacrylate to make corrected plastic achromatic lenses.

One of the limitations of polystyrene for many applications is its inability to tolerate excessive heat, and although the modification with divinyl benzene increases its resistance to heat distortion, it does so at the expense of mouldability. In order to increase the heat resistance of polystyrene and maintain mouldability, the monomer has been copolymerized with various nitrogen-containing compounds such as acrylonitrile, fumaric nitrile and vinyl carbazole. The increase in softening point is attained at the sacrifice of colour. Consequently, extensive investigation was carried out in the direction of introducing various groups into the styrene nucleus in an attempt to improve the heat distortion directly. One of the methods that proved successful involves the introduction of multiple halogens into the aromatic nucleus.

Polyvinyl Carbazole Resins.—Reaction of acetylene with carbazole

to a plastic possessing high heat resistance and excellent electrical properties; but the brittleness of the product limits its uses to specialized industrial applications.

Polyethylene Resins.—Although ethylene is the simplest unsaturated compound, it proved to be one of the most difficult to convert into a high-molecular-weight polymer. The polymerization requires extremely high pressures and moderately high temperatures to effect conversion. As might be predicted from its structure, polyethylene, $-(CH_2-CH_2)_n-$, is completely nonpolar and possesses a low power

factor and a low dielectric constant. Being highly symmetrical, it is also crystalline, and in common with other crystalline polymers, thin sheets of the resin exhibit high resistance to penetration by water vapour. At ordinary temperatures the resin is highly resistant to attack by organic and inorganic reagents. At moderate temperatures, the resin can be dissolved in certain organic liquids and such solutions can be applied as a coating, but satisfactory results are obtained only by keeping the object coated in a heated condition until the solvent has evaporated. Polyethylene, however, can be applied more easily directly by extrusion of the molten plastic. It proved suitable for insulating high-frequency and high-voltage circuits. Because of its low water permeability, extensive tests were carried out with a view of using the resin in submarine cables.

Trade Names.—Plastics are known and sold commercially under various trade names. A single resin may be sold under a multiplicity of names arising from the fact that the resin manufacturer sells the resin under his own trade name while the moulder may offer this resin in its moulded form to the public under his own distinctive brand name. Moreover, the same chemical composition may frequently be offered to several different consuming industries under several different individual names. As knowledge gradually accumulates concerning the chemical nature and constitution of resins and plastic materials, the custom is becoming established of associating, directly or indirectly, the trade name along with the chemical constitution.

PLATA, RÍO DE LA, or RIVER PLATE, a funnel-shaped estuary, on the east side of South America, extending west-northwest from the sea about 200 m. The discovery of the South sea by Balboa, then governor of Castilla del Oro, of which Darién formed a part, created a lively desire to learn something of its coast line, and the year following (in 1514) the Spanish monarch concluded a navigation contract with Juan Díaz de Solís, then *ploto mayor*, to search for a strait connecting the Atlantic with the newly found ocean. De Solís set sail from the port of Lepe on Oct. 8, 1515, reached the Bay of Rio de Janeiro on Jan. 1, 1516, and continuing southward to lat. 35° entered the great estuary now known as the Plata, which, for a short period of time, was called the De Solís and the Mar Dulce. Ascending it to the vicinity of the island of Martín García, near the mouth of the Paraná river, De Solís was ambushed and killed early in 1516 by Charrúa Indians. In 1520 Magellan explored the Río de la Plata, and discovered and navigated the straits which bear

his name. In 1526 Cabot ascended the Mar Dulce, discovered the Paraná river and reached a point on the Paraguay near the site of the present city of Asunción. Here he obtained silver ornaments by barter from Guarani Indians. The receipt of these silver baubles caused the name of Río de la Plata to be applied to the third greatest river of the western continent.

The extreme breadth of the river at its mouth is 138 mi. It narrows quickly to 57 mi at Montevideo, and to 25 mi at its head, where it receives the Paraná and Uruguay rivers. Its northern or Uruguayan shore is somewhat elevated and rocky, while the southern or Buenos Aires one is very low. The whole estuary is very shallow, and in no place above Montevideo exceeds 36 ft in depth at low water. The bottom generally consists of sand covered with from 10 to 20 ft of water. A dredged channel of about 31 ft in depth leads from the port of Buenos Aires 20 mi. east to deep water. Winds and tides considerably affect the depth of the channel. The Plata is simply the estuarine receptacle of two mighty streams, the Uruguay and Paraná which drain the Plata basin. This has an area of 1,198,000 sq mi., or over two and one-half times that of the Pacific slope of the Andes, and comprises the most fertile and healthful part of Brazil, a large portion of the Argentine republic, the whole of Paraguay and southeastern Bolivia, and most of Uruguay.

The Uruguay and Affluents.—The Uruguay river has a length of about 1,000 mi. Many small streams from the western slope of the Brazilian Serra do Mar unite, in about 27° 45' S to form this river, which then flows WNW, serving as the boundary between the states of Santa Catarina and Rio Grande do Sul, as far as 54° W, near which it receives a considerable tributary from the north, called the Pepiri Guazú. Between 27° 58' and 33° 34' S. three important tributaries join it from the east—the Ijuí, the Ibicuí and the Negro.

high lands. At the river Pepiri Guazú it turns suddenly to the southwest, and continues this course to its junction with the Paraná and Plata. Near Fray Bentos, 61 mi. before reaching the Plata, it forms a great lake, about 56 mi long and from 4 to 6 mi wide. At Punta Gorda, where it debouches into the Plata, it is about 1 mi wide, but is 90 ft. deep. From the Pepiri Guazú junction its banks are high and covered with forest as far down as 27° 30' S, where the river is 2,300 ft. wide and from 10 to 40 ft. deep. The Uruguay is much obstructed by rocky barriers. Four miles below its confluence with the Pepiri Guazú it has a cataract, about 8 mi long, with a total fall of 26 ft. at low water. The river near the Pepiri Guazú is 1,550 ft. wide, but about 14 mi before reaching the cataract its width is reduced to 600 ft. Along the cataract it is closed in between high precipitous walls of black rock only 70 ft. apart. Above Punta Gorda, 212 mi., is the Salto Grande, which has a length of 15 mi. of rapids, the greatest single fall being 12 ft., and the difference of level for the entire length of the reefs 25 ft. Nine miles below the Salto Grande is the Salto Chico, which bars navigation during six months of the year, but in floodtime may be passed in craft drawing 5 ft. of water. The Uruguay can be navigated at all seasons by vessels of 4½ ft. draught as far up as the Salto Chico, and of 14 ft. up to Paysandú for a greater part of the year. Fray Bentos may be reached all the year round by any vessel that can ascend the Paraná. Above the navigable lower river there is launch and canoe navigation for many hundreds of miles upon the main artery and its branches, between the rapids which are met with from time to time. The Uruguay has its annual floods, due to the rains in its upper basin. They begin at the end of July and continue to November, attaining their maximum during September and October. Except in floods, it is a clear-water stream, and even at its highest level

carries comparatively little silt.

The Paraná and Its Affluents.—The Paraná (the "Mother of the Sea" in Guarani) drains a vast area of southern Brazil. It is formed by the union of the Rio Grande and Paranaíba, and is about 1,600 mi long from its source in Goiaz to its junction with the Paraguay, and thence 600 mi to the Plata estuary. Its average width for the latter length is from 1 to 3 mi. Its Rio Grande branch descends from the slope of the Serra da Mantiqueira, in the region where the orographic system of Brazil culminates near the peak of Itatiaiyassú, almost in sight of Rio de Janeiro. It is about 680 mi long, but only navigable in the stretches between the many reefs, falls and rapids which interrupt its regular flow.

Besides these rivers, the Paraná has many long and powerful affluents from the Brazilian states of São Paulo and Paraná. Most of them, although obstructed by rapids, are navigable for launches and canoes. Among the eastern tributaries are the Tieté, the Paranapanema, formerly known as the Anemby, and the Iguaçu. The Paranapanema is about 600 mi long, and rises in an offshoot of the Serra Paranapiacaba which overlooks the Atlantic ocean.

The Iguaçu, also called the Rio Grande de Curitiba has its sources on the slopes of the Serra do Mar of Brazil, and flows nearly west, through thick forests, along the line of 26° South. Its navigation is difficult even for small craft, as it is full of reefs, rapids and cataracts. Sixteen miles above its mouth is the magnificent Cataratas del Iguaçu, sometimes called the Victoria Falls, round which canoes have to be transported 37 mi. before quiet water is again reached. The width of the falls, measured along their crest or edge, is 2½ mi.; part of the river takes two leaps of about 100 ft. each, but a portion of it plunges down the whole depth in unbroken mass. Its mouth is about 800 ft. wide, and the depth in mid-river 40 ft.

The Paraná has unobstructed navigation for about 400 mi between the Falls of Urubupunga and the Falls of Guará in 24° 3' S, where it forms a lake 4½ mi. long and 2½ mi. wide, preparatory to breaching the Serra de Mbaracayú, which there disputes its right of way. It has then a deep gorge through the mountains for a length of about 2 mi where it is divided into several channels, filled with rapids and cataracts. It finally gathers its waters into a single volume, to plunge with frightful velocity through a long canyon only about 200 ft. wide. From these so-called Falls of Guará or "Sete Quedes," as far as its confluence with the Paraguay river, the Paraná has carved a narrow bed through an immense cap of red sandstone, along which it sometimes flows with great rapidity, occasionally being interrupted by dangerous narrows and rapids, where the banks in some places close in to a width of 450 to 600 ft., although the average is from 1,200 to 1,600 ft. At the southeast angle of Paraguay the Paraná is turned westwards; but before escaping from its great sandstone bed it is obstructed by several reefs, notably at the rapids of the Apipé, which are the last before it joins the placid Paraguay, 130 mi farther on.

The Paraguay.—The river Paraguay, the main affluent of the Paraná, rises in Mato Grosso, in the vicinity of the town of Diamantino, about 14° 24' South. It flows southwestwards, as far as São Luiz de Cáceres, along the foot of the high plateau which divides it from the São Lourenço (Cuaabá) river to the east, and then, turning southwards, soon reaches the morass expansion of Xarayes, which it traverses for about 100 mi. A few miles below São Luiz de Cáceres it receives an affluent from the northwest, the Jaurú, which has its source nearly in contact with the headwaters of the Guaporé branch of the river Madeira. From the junction of the São Lourenço with the river Paraguay, the latter, now a great stream, moves sluggishly southwards, spreading its waters, in the rainy season, for hundreds of miles to the right and left, as far south as 20°, turning vast swamps into great lakes—in fact, temporarily restoring the region, for thousands of square miles, to its ancient lacustrine condition.

On the west side of the upper Paraguay, between about 17° 30' and 19° S., are several large, shallow *lagunas* or lakes which receive the drainage of the southern slopes of the Chiquitos sierras, but represent mainly the southwest overflow of the vast morass of Xarayes. The principal of these lakes, naming them from north

to south, are the Uberaba, the Gaiba, Mandioré and the "Bahia" de Cáceres. The Uberaba is the largest. It is in great part surrounded by high ground and hills, but its southern coast is swampy and flooded during the rainy season. The west shore is historic. Here, in 1543, the conquistador, Martínez de Irala, founded the "Puerto de los Reyes," with the idea that it might become the port for Peru; and from Lake Gaiba several expeditions, in Spanish colonial days, penetrated 500 mi. across the Chaco to the frontier of the empire of the Incas. At the Puerto de los Reyes Bolivia laid out a town (Puerto Suárez) in 1900 in the hope that the port would serve as an outlet for that commercially suffocated country, there being no other equally good accessible point for Bolivia on the Paraguay river.

South of the São Lourenço, the important rivers entering the Paraguay from the east are the Taquiri, which rises in the Serras das Furnas, on the southern extension of the Mato Grosso tableland; the Miranda, with many branches, draining a great area of extreme southern Mato Grosso, and the Apa, which forms the boundary between Paraguay and Brazilian Mato Grosso.

The Pilcomayo.—The Pilcomayo rises among the Bolivian Andes north of Potosí and northwest of Sucre, races down the mountains to their base, crosses the Chaco plains, and pours into the river Paraguay near Asunción. It does not receive any branch of importance until it reaches about $21^{\circ} 51'$ S., where it is joined from the southwest by the river Pilaya, upon which Tupiza, a city in southern Bolivia, is situated. Just below the junction is the Fall of Guarapetendi, 23 ft. high. From this point to the mouth of the Pilcomayo the distance in a straight line is 480 mi., although by the curves of the river, which is extremely tortuous, it is about double that distance. The river bifurcates at $21^{\circ} 51'$ S., but again becomes a single stream at $23^{\circ} 43'$, the right channel being the greater in volume. It is probable that between 23° and 24° S. it throws three great arms to the river Paraguay, the upper portions of which have yet to be explored, but the lower parts have been examined for 100 to 200 mi. up from the Paraguay. From 180 to 200 mi. above its mouth the Pilcomayo filters through a vast swamp about 100 mi. in diameter, through which there is no principal channel. This swamp, or perhaps shallow lagoon, is probably partly drained by the river Cosñasho, which reaches the Paraguay between the Pilcomayo and Aguay-guará. A northern branch of the Pilcomayo, the Brazo Norte, the junction being at $24^{\circ} 56'$ S., is probably also a drainage outlet of the same great swamp.

For the first 100 mi. below the Fall of Guarapetendi the Pilcomayo is from 600 to 1,000 ft. wide, but it so distributes its waters through its many bifurcations, and loses so much from infiltration and in swamps, and by evaporation from the numerous lagoons it forms on either side of its course, that its channel is greatly contracted before it reaches the Paraguay. From Sucre to the Andean margin of the Chaco, a distance of about 350 mi. by the river, the fall is at least 8,000 ft.—a sufficient indication that its upper course is useless for purposes of navigation. Its lower course is of little value for commercial purposes.

The Bermejo.—The Bermejo river flows parallel to the Pilcomayo, and enters the Paraguay a few miles above the junction of this with the Paraná. Its numerous sources are on the eastern frontage of the inland Andes, between the Bolivian town of Tarija and the Argentine city of Jujuy. In $23^{\circ} 50'$ S. the Bermejo receives its main affluent, the San Francisco, from the southwest. The latter has its source in about $22^{\circ} 30'$ S., and, under the name of Río Grande, runs directly southwards, in a deep mountain valley, as far as Jujuy. It then turns eastwards for 50 mi., and is joined by the Lavaca from the southwest. These two streams form the San Francisco, which from Jujuy runs in a southeasterly direction to the Bermejo. From its junction with the latter it streams the Bermejo flows southerly, and, at the mouth, which is in average width in its main channel of about 600 ft., it begins narrowing at times to 160 and even 100 ft. In its course between its bifurcations and ramifies into many channels for nine enormous islands and frequently leaves old beds for new ones.

Since the exploration of the Bermejo by Páiz in 1721 it has often been examined from its sources to its mouth with a view to

ascertaining its navigability. Like the Pilcomayo, the Bermejo is of little use owing to swift currents, shoals, quicksands, snags and fallen trees.

The Salado.—The Salado, about 250 mi. southwest of and approximately parallel to the Bermejo, is the only great tributary which the Paraná receives from the west below its confluence with the Paraguay. Its extreme headwaters, the Santa María and Calchaqui, which unite near the town of San Carlos and form the river Guachipas, drain a much broken Andean region lying between 24° and $26^{\circ} 30'$ S. in the Argentine province of Salta. Having received the Añas, the Guachipas runs northwards about 50 mi., and then it changes its name to the Juramento, which is retained until the river reaches the Chaco plains at the base of the foothills of the Andes. Here it becomes the Salado. It joins the Paraná near Santa Fé in $31^{\circ} 39'$ S. and $60^{\circ} 41'$ W. Explorers of the Salado, inclusive of Captain Page in 1855, claim that its lower half is navigable, but the many efforts which have been made to utilize it as a commercial route have all resulted in failure.

The Pilcomayo, the Bermejo and the Salado erode quantities of the Pampean material, dissolve it into silt and pour it into the Paraguay and Paraná rivers. The engineer, Pelleschi, estimates that "the soil annually subtracted from the territory of the Chaco by the Bermejo alone equals 6,400,000 cubic yards."

Lower Course of the Paraná.—From $31^{\circ} 30'$ S. to the Plata estuary the western bank of the Paraná is a precipitous bluff of reddish clay, varying from 25 to 75 ft. above mean river level. It is being gradually undermined, and tumbles into the water in great blocks, adding to the immense volume of silt which the river carries. The Paraná is lowest in December, it rises in January, February and March, reaching its greatest height in March. It is steady in April, May and June, but falls and rises irregularly during the next three months. The difference between low and high river is generally about 12 ft., depending upon the varying quantity of rains in Brazil and the melting of the Andean snows. Below its junction with the Paraguay the Paraná has an average current of 2½ mi. an hour, and the river varies in width from 1 to 3 mi., at low water; but in floods it seems almost a continuous lake, broadening to 10 and 30 mi. and burying many of its numerous islands and marginal swamps under a vast sheet of water, and obliterating its many parallel lateral channels and connecting canals.

Islands of Paraná.—In the middle Paraná, from the mouth of the Iguassú to the mouth of the Paraguay river, there are many islands, some of them large, rocky and high above the river. From Paraguay to the city of Rosario, islands are numerous, many of them of great area; and again below Rosario they soon increase in number and size until the Plata estuary is reached. In flood-time the upper portion of the trees being out of water, they have the appearance of floating forests. Then the river often makes wild work with its banks, and builds up or sweeps away entire islands, leaving deep channels instead. The lower delta of the Paraná does not share in these phenomena, its islands and main channels appear more fixed. This probably is due to the less elevation attained by the waters in floodtime, and the numerous branches which distribute them into the Plata estuary. This must have extended, in a very recent geological period, inland from its present head to at least 32° S., but the enormous quantity of silt which the Paraná receives from its Paraguay affluent, and from the tributaries which reach it from the Andes, has filled this length of about 220 mi. with these muddy islands, which rest upon a sandy bed of great depth.

Paraná Delta.—The frontage of the Paraná delta is 40 mi. across, almost in a straight line from north to south. Through this the river finds its way to the Plata by 11 outlets, large and small, the two principal ones being the Paraná Guazú and the Paraná Bravo. In September (low river) the depth of water in the Paraná Guazú is at least 20 ft., the least depth of the Paraná Bravo is 36 ft. Because the depth of water in the Paraná is controlled by seasonal variations it is difficult to state categorically the draught of vessels that can ascend to various points along the river. At the port of Rosario, 222 mi. above Buenos Aires, the lowest monthly average of the river level is just under 28 ft. At

Santa Fé, 312 mi above Buenos Aires, the river level varies between 10 and 27 ft, but a depth of 20 ft in the entrance channel and port is maintained by constant dredging. The maximum draughts that can use the various channels in the Paraná and Paraguay rivers are published in daily bulletins, available in Buenos Aires and all up-river ports.

Communications.—The expenditure of hundreds of millions of dollars for dredging, port improvements and rail and highway connections greatly increased the commercial importance of scores of towns and cities located on the Plata-Paraná-Paraguay river system. The Compañía Argentina de Navegación Mihanovich Ltda., operating in 1941 a fleet of more than 400 boats, launches and barges, maintains regular passenger and freight services between Buenos Aires, Montevideo and all ports on the Plata, Paraguay, Alto Paraguay, Alto Paraná and Uruguay rivers. River boats of Lloyd Brasileiro operate on a regular schedule between Montevideo and Corumbá, Brazil, and the Compañía Uruguaya de Navegación and the Línea Río Uruguay operate steamers between Montevideo, Salto and intermediate ports on the Uruguay river and some of its tributaries. Ocean-going vessels can ascend the Paraná to Santa Fé and Bajada Grande (port of the city of Paraná), and the Uruguay to Concepción del Uruguay, or, when the river permits, to Colón. Coastal vessels have a somewhat greater range and are able to sail varying distances up several of the tributaries, including the Gualaguay, Gualaguaychú, Victoria, Paraná Pavón, Ibicuy and Negro. River boats ascending the Paraná to Asunción may be of somewhat deeper draught than those that can navigate the Alto Paraná. Because of this, Corrientes has become an important transfer point for passengers and cargoes destined for ports along the Alto Paraná. The Guará falls are circumvented by a railroad between Porto Mendes, Brazil, and a point 38 mi up river. The journey from Buenos Aires to Asunción, a distance of approximately 900 mi, is made in 33 days by boat. Northward from Asunción the Alto Paraguay is navigable to small craft for more than 1,000 mi., providing the principal outlet for a vast region that produces large quantities of cattle, lumber and quebracho. In addition to being ports on the Alto Paraguay, Porto Esperanza and Corumbá, Brazil, and Puerto Suárez, Bolivia, have direct rail connections with São Paulo. Throughout the Plata region the gradual introduction of modern agricultural implements has led to an increase in production, which is reflected in the growth and development of industries and a significant increase in river traffic.

PLATAEA or PLATAEAE, an ancient Greek city of Boeotia, situated close under Mt. Cithaeron, near the passes leading from Peloponnesus and Attica to Thebes, and separated from the latter city's territory by the River Asopus. Though one of the smallest Boeotian towns, it stubbornly resisted the centralizing policy of Thebes. In 519 B.C. it invoked Sparta's help against its powerful neighbour, but was referred by king Cleomenes to Athens (for the date, see Grote's *History of Greece*, ed 1907, p 82, note 4). The Athenians secured Plataea's independence, and thus secured its enduring friendship. In 490 the Plataeans sent their full levy to the assistance of the Athenians at Marathon, and during the invasion of Xerxes they joined eagerly in the national defense. At Artemisium they volunteered to man several Athenian ships, and subsequently abandoned their town to be burnt by Xerxes. In 479 they fought against the Persians under Mardonius in the decisive battle which bears the name of the city. (For an account of the battle see **GRAECO-PERSIAN WARS**) Their great victory was celebrated by annual sacrifices and a Festival of Liberation (*Eleuthera*) in every fourth year at Plataea, whose territory moreover was declared inviolate.

In spite of this guarantee Plataea was attacked by Thebes at the beginning of the Peloponnesian War (431) and formally besieged by the Peloponnesians (420-27). The garrison after capitulating was put to death, and the city razed by the Thebans. The remaining Plataeans received a qualified franchise in Athens, and in 421 were settled on the territory of Scione. Expelled by Lysander in 404 they returned to Athens, until in 387 Sparta restored them in their native town as a check upon Thebes.

The city was again destroyed by Thebes in 375, and the inhabitants once more became citizens of Athens. Plataea was rebuilt by Philip and Alexander of Macedon, and during the rest of antiquity enjoyed a safe but obscure existence. It continued to flourish in Byzantine and Frankish times. The walls of the town, which at various periods occupied different portions of the triangular ledge on which it stood, remain partly visible. Recent excavations have discovered the Heraeum, but the temple of Athena the Warlike, built from the Persian spoils and adorned by the most famous artists, has not been identified. **AUTHORITIES.**—Strabo p 411; Pausanias ix 1-4; Herodotus vi. 108, viii. 1, ix. 35-85; Plutarch, *Aristides*, 11-21; Thucydides ii 1-16, 71-78, iii 20-24, 52-68; Isocrates, *Plataicus*; G B Grundy, *The Topography of the Battle of Plataea* (London, 1894) and *Great Persian War* (London, 1907), ch xi; W Woodhouse in *Journal of Hellenic Studies* (1898), pp 33-59; H B Wright, *The Campaign of Plataea* (New Haven, 1904); R W Macan, *Herodotus*, vii-xv (London, 1908), appendix; W M Leake, *Travels in Northern Greece*, ch xvi, pp 333-367 (London, 1835); *Amer Journ. of Archaeology*, 1890, pp 445-475; 1891, pp 390-405. PLATE, the common name for the electrode from which the current flows through the vacuum space in a radio vacuum tube.

PLATEAU, JOSEPH ANTOINE FERDINAND (1801-1883), Belgian physicist, was born at Brussels on Oct. 14, 1801, and died on Sept. 15, 1883 at Ghent, where he had been professor of physics from 1835. The more original investigations of Plateau refer chiefly to physiological optics and molecular forces. We owe to him the "stroboscopic" method of studying the motion of a vibrating body, by looking at it through equidistant radial slits in a revolving disk. In 1843 Plateau became permanently blind. He published an analytical catalogue of memoirs from the earliest times to the end of the 18th century on his favourite theme of subjective visual phenomena. This blind man's investigations on molecular forces, embracing hundreds of novel experiments whose results he saw only with others' eyes, are described in his great work *Statique expérimentale et théorique des liquides soumis aux seules forces moléculaires* (2 vols, 1873).

PLATEN-HALLERMUND, AUGUST, GRAF VON (1796-1835), German poet and dramatist, was born on Oct. 24, 1796, at Ansbach, and entered the Bavarian life guards in 1814. He took part in the short campaign in France of 1815; he then obtained a long leave of absence, and after a tour in Switzerland and the Bavarian Alps, entered the University of Würzburg in 1818 as a student of philosophy and philology. In 1819 he removed to Erlangen, where he sat at the feet of F. W. J. von Schelling. As a result of his Oriental studies he published a little volume of poems—*Ghaselen* (1821), each consisting of from ten to twenty verses, in which he imitates the style of Ruckert; *Lyrische Blätter* (1821), *Spiegel der Höfz* (1822); *Vermischte Schriften* (1822), and *Neue Ghaselen* (1823).

Though Platen was at first influenced by the school of Romanticism, and particularly by Spanish models, yet the plays written during his university life at Erlangen, *Der gläserne Pantoffel*, *Der Schatz des Rhampsinet*, *Benarag*, *Treu um Treue*, *Der Turm mit sieben Pförten*, show a clearness of plot and expression foreign to the Romantic style. His antagonism to Romanticism became more and more pronounced, and he attacked its extravagances in the witty "Aristophanic" comedies *Die verhängnisvolle Gabel* (1826) and *Der romantische Oedipus* (1828). In 1826 he visited Italy, which he henceforth made his home, living at Florence, Rome and Naples. *Der romantische Oedipus* earned for him the bitter enmity of Karl Immermann and Heinrich Heine, but he retained many staunch admirers, who delighted in the purity of the subject matter of his productions and their beauty of form and diction. In Naples were written his last drama *Die Liga von Cambray* (1833) and the delightful epic fairy-tale *Die Abassiden* (1830; 1834), besides numerous lyrical poems, odes and ballads. He died at Syracuse on Dec. 5, 1835. Platen's odes and sonnets,

to which must be added his *Polenieder* (1831), expressing his sympathy for the Poles in their rising against the rule of the Tsar, rank among the best classical poems of modern times.

Platen's *Gesammelte Werke* were first published in one volume in 1839, and have been frequently reprinted, a convenient edition is that edited by K. Goedeke in Cotta's *Bibliothek der Weltliteratur* (4 vols., 1882). His *Tagebuch* (1796-1835), was published in its entirety by G. von Laubmann and L. von Scheffer (4 vols., 1896-1900). See P. Besson, *Platen, étude biographique et littéraire* (1894); A. Fries, *Platen-Forschungen* (1903); E. Petzet, *Platen's Verhältnis zur Romantik in sein ständes Zeit* (1911); R. Schiöser, *August Graf von Platen. Ein Bild seines geistigen Entwicklungsganges und seines dichterischen Schaffens* (Munich, 1910-13).

PLATERESQUE, the earliest of the styles of Spanish Renaissance, so called, either because the Renaissance found its first popular Spanish expression in silverware (*platero*, silver-smith), or because its rich and delicate ornament resembled silver-smith work. It is characterized by the application to forms structurally simple, of extremely rich ornament, distantly based on Italian Renaissance forms, using pilasters, entablatures, carved rectangular panels, shallow niches, much heraldic ornament and rich pierced, scrolled cresting. Its courtyards, usually with two or more openings on the upper floor, above a single opening below, are famous for their decorated columns, sometimes simulating balusters, their bracketed capitals and their graceful decay. Owing to Moorish influence, there is a common tendency to carry the decoration around the door over the full height of the wall above. Decorative ironwork, as in the church *rejas* (*qv*), or open metal screens, was highly developed. The style embraces, generally, the first half of the 16th century, but its decorative ideals influenced not only the classic period which followed, but the Baroque as well. Characteristic examples are the hospital of Santa Cruz, Toledo, by de Egaz (1504-16), the college at Alcalá de Henares, by Gumiel (1500-17), the university and Irish college at Salamanca, the Casa de las Conchas at Salamanca and the Infanta at Guadalajara. (See RENAISSANCE ARCHITECTURE.)

(T F H)

PLATERSPIEL, **PLATERPFIFE**, a mediaeval simplified bagpipe, consisting of an insufflation tube, a bladder and a chanter, the double reed in its socket at the top of the chanter being concealed within the bladder. In the *platerspiel* we recognize the early mediaeval chorus (*qv*) a word which in mediaeval Latin was frequently used also for the bagpipe, while in its later forms it was practically identical with the cromorne (*qv*).

PLATINUM, a very heavy steel-grey metal of great usefulness in the chemical and mechanical arts.

Platinum was probably known in the impure state from very early times, but because of its physical properties and especially its high melting point it was impossible to work it by any of the arts then known and it therefore remained as an unnamed substance (Symbol Pt, atomic number 78, atomic weight 195.23). It was probably the metal alluded to in the early part of the 16th century by Scaliger, who refers to a metal incapable of being fused obtained from the mines in Mexico and Darien. About the middle of the 18th century it was introduced into Europe in small quantities and attracted the notice of various chemists. Scheffer, in a paper read before the Stockholm Academy entitled "On white gold or the seventh metal, termed in Spanish *platina del Pinto*" (1752), showed that it was insoluble in nitric acid but soluble in aqua regia, was precipitated from its solutions by mercury, and was infusible at the highest temperature of the furnace. He also dealt with some of its alloys and discovered that it was fusible when mixed with arsenic. Platinum was melted by Macquer and Baumé in 1758 in the focus of a powerful burning glass. Count von Sickingen in 1772 prepared the metal in the form of foil and wire and showed that it was soluble in nitric acid when alloyed with a large quantity of silver. For the later history of platinum, its occurrence and separation from the other metals, see PLATINUM METALS and RUTHENIUM, RHODIUM, PALLADIUM, OSMIUM and IRIIDIUM.

Platinum in the massive state is a greyish-white metal having a specific gravity of 21.4 and is exceedingly malleable and ductile. It melts at about 1,755° C and volatilizes readily in the electric furnace. Its latent heat of fusion is 27.18 calories. It is a bad

conductor of heat and electricity. When pure it is a soft metal and on this account is not suitable for some purposes, but on alloying it with iridium in small amounts the hardness is greatly increased. It is capable of being welded at a temperature near its melting point, but for easier working at a lower temperature gold is used as a solder in repairing damaged crucibles and other articles. It alloys easily with all the other metals of its own group, likewise with gold, silver and lead, but is scarcely acted upon by metallic mercury. It has been obtained in the crystalline condition by distillation in the electric furnace or by heating the fluoride to a red heat (Moissan). Spongy platinum is readily produced by ignition of the double chloride $(\text{NH}_4)_2\text{PtCl}_6$; it possesses a much greater surface area than the massive metal and hence is more active when employed in catalysis. Platinum black is best prepared by warming a solution of any of the chlorides or double chlorides of platinum in caustic alkali with alcohol or some similar reducing agent, or by dissolving the lead in nitric acid from a not very rich lead-platinum alloy. It has an enormous surface area and hence is the most usual form in which platinum is employed in catalytic reactions. The platinum black, for convenience in handling and also to minimize loss, is usually deposited upon some suitable material such as asbestos or barium sulphate. Colloidal platinum can be obtained in solution by passing an electric arc between platinum terminals under pure water.

Uses.—Platinum is used in the laboratory in the form of dishes, crucibles and weights, although a small amount of iridium is generally added to increase its hardness and hence its durability. Platinum vessels, however, should never be used for heating caustic alkalis, as they undergo corrosion producing platinate, and no metal of low melting-point should ever be heated in them. At one time platinum vessels were almost exclusively used in concentrating sulphuric acid (*qv*) made by the chamber process, this use has been abandoned as sulphuric acid made by the contact process is already concentrated, and the chamber acid is now concentrated in cheaper vessels.

Platinum is the best catalyst for the manufacture of sulphuric acid by the contact process; at a temperature below a red heat it is capable of causing the reaction $2\text{SO}_2 + \text{O}_2 = 2\text{SO}_3$ to be nearly completed. The resulting SO_3 is dissolved in water till an acid of the required strength is obtained (see SULPHURIC ACID). Its use for this purpose has been partly given up, as some cheaper catalysts such as the oxides of iron and chromium, although less efficient, have been found more economical. In this process platinum is always used as platinum black. The material to be platinumized (asbestos, pumice, brick, barium sulphate, etc.) is dipped in a dilute solution of platinum chloride, dried and ignited, an enormous catalytic surface of platinum black being thus produced. Another large and rapidly extending use for platinum is in the catalytic production of nitric acid from ammonia by oxidation. A mixture of ammonia gas and air (or oxygen) in the right proportion is passed in a very rapid stream over a network of heated platinum gauze. Either ammonium nitrate or nitric acid can be produced according to the proportions of oxygen and ammonia in the reaction mixture. The reaction is exothermic, and by adjusting the rate of flow of the mixed gases the reaction temperature can be kept constant.

Platinum or, better, iridium-platinum alloy is the most suitable anode material for electrolysis of all kinds. It remains unattacked under practically all conditions, but owing to the initial expense, some form of carbon, especially Acheson graphite, is now generally used for this purpose. Two methods of measuring high temperatures depend upon the use of platinum; the first is the platinum resistance thermometer, which depends upon the change of resistance of a platinum coil with temperature when a constant current is passing through it, the second is the use of a platinum and rhodium-platinum thermocouple. By careful calibration either of these instruments is capable of giving a very exact measurement of high temperatures. As platinum is not oxidized by air at the temperature of the electric spark, it is very suitable in electro-technics for contact-points of magnetos and induction coils and the armatures of electric bells, it can

also be used when caused to glow by the passage of an electric current as a heating-element; for some of these uses it has now been displaced by cheaper materials, one of the best being a chromium-nickel alloy known as nichrome.

Platinum is extensively used for some surgical instruments such as needles for hypodermic syringes, for the metal can be sterilized even in the flame of a match, it is also used in the incandescent state as an electric cautery. Unfortunately it cannot be hardened sufficiently to make a good cutting edge. In dentistry platinum was formerly used extensively for making dental plates, etc., as an alloy of 2 parts of silver to one of platinum possesses the same coefficient of expansion as the hard porcelain-like material of which artificial teeth are composed. Owing to the rise in the price of platinum, gold or gold alloys have now almost entirely displaced it for this purpose. The use of platinum in jewellery is considerable, during World War I palladium replaced it to a large extent and now an alloy called white gold, which consists chiefly of gold alloyed with a small quantity of either palladium or platinum, is largely displacing it. Another use for platinum is the production of photographic prints by the platino-type process. These prints are of great beauty owing to the variety of tones that can be thus produced, and have the advantage over silver prints of being absolutely permanent.

Platinum Compounds.—Platinum does not combine directly with oxygen at any temperature, although in the molten state it absorbs several times its volume of this gas, which, however, is released when the metal cools. Four oxides of platinum are obtainable by indirect methods, viz., PtO , Pt_2O_3 , PtO_2 , and PtO . Of these, PtO and PtO_2 are important as they are the bases of the platinumous and platinumic salts. *Platinum oxide*, PtO , is obtained by gentle ignition of the corresponding hydrate, $Pt(OH)_2$, which is obtainable by precipitating either $PtCl_4$ or K_2PtCl_6 with caustic alkali. It is a black powder, soluble in acids when freshly prepared. *Platinum oxide*, PtO_2 , is known in the hydrated form $Pt(OH)_4$, but only a portion of the combined water can be removed before deeper decomposition begins to take place. The hydroxide is obtained by adding excess of caustic soda to a boiling solution of $PtCl_4$, which gives a yellow solution of sodium platinate, and then precipitating the cold solution with acetic acid. It is a white or yellowish solid soluble both in dilute acids and in alkalis when freshly prepared, but after losing water on heating it becomes black and insoluble. The peroxide, PtO_2 , is obtainable by electrolyzing an alkaline solution of $Pt(OH)_4$ at $0^\circ C$. It is a red-brown unstable solid which readily parts with some of its oxygen at ordinary temperatures.

Two well-defined chlorides of platinum are known—platinum chloride, $PtCl_4$, and platinum chloride, $PtCl_6$. *Platinum chloride* is formed by heating chloroplatinic acid to $300^\circ C$ or evaporating a solution of the same substance with absolute alcohol to dryness several times. It is a greenish or sometimes brownish substance insoluble in water but soluble in hydrochloric acid or alkali chloride solutions, with which it forms double chlorides of the form M_2PtCl_6 , these are the alkali salts (platinichlorides) of chloroplatinous acid, H_2PtCl_4 . This acid, which is known only in solution, can be obtained also from either its barium or silver salt by exact precipitation by means of sulphuric or hydrochloric acid respectively. The best known salt of the acid is the potassium compound, which is easily produced by reducing a boiling solution of potassium chloroplatinate with sulphur dioxide. It crystallizes in dark red prisms easily soluble in water, and in the case of certain unfortunate persons, traces of it act as a violent irritant to the mucous membrane of the eyes and nose. Platinumous chloride combines with various unsaturated substances to form double compounds; it combines directly with carbonic oxide at $250^\circ C$ to form three compounds, $PtCl_4 \cdot CO$, $(PtCl_4)_2 \cdot 3CO$; and $PtCl_4 \cdot 2CO$, with phosphene to form $PtCl_4 \cdot 2COCl_2$, with ethylene to produce $PtCl_4 \cdot 2C_2H_4$; and with phosphorus trichloride to form compounds $PtCl_4 \cdot PCl_3$ and $PtCl_4 \cdot 2PCl_3$.

Platinum chloride, $PtCl_6$, is formed by the action of chlorine on platinum at a temperature below 500° . If platinum is dissolved in aqua regia or in hydrochloric acid in a stream of chlorine and the solution is evaporated with hydrochloric acid till free from

nitric acid, reddish-brown crystals of chloroplatinic (platinichloric) acid, $H_2PtCl_6 \cdot 6H_2O$, are produced. These if ignited in a stream of hydrogen chloride gas at 165° give a residue of $PtCl_4$ as a reddish-brown, very hygroscopic, crystalline mass. The pure chloride, however, is rarely met with, and the platinum chloride of commerce is the compound $H_2PtCl_6 \cdot 2H_2O$ formed by heating the hexahydrated compound to $100^\circ C$. Chloroplatinic (platinichloric) acid is a weak acid, it reddens litmus paper and decomposes metallic carbonates producing the corresponding platinumichlorides. It forms potassium and ammonium compounds which are nearly insoluble in water and quite insoluble in a mixture of alcohol and ether, the corresponding sodium compound is soluble in this mixture, and this circumstance affords the best method of separating potassium from sodium quantitatively. Chloroplatinic (platinichloric) acid forms compounds with organic bases which are usually difficultly soluble in water.

Platinum is not attacked by fluorine at a low temperature, and advantage of this was taken by Moissan when he first isolated that element and by Moissan and Dewar when they first liquefied this gas. At higher temperature (500° – $600^\circ C$) Moissan obtained two fluorides, PtF_4 and PtF_6 . Platinum does not readily form stable salts with oxy-acids. A sulphate $Pt(SO_4)_2$ is said to have been produced by dissolving platinum hydride in sulphuric acid but no nitrate of platinum is known. A series of salts known as platino-nitrates having the general formula $M_2Pt(NO_3)_4$, is well known, and another series, the platino-oxalates of the composition $M_2Pt(C_2O_4)_2$, has also been recorded. Two sulphides of platinum, PtS and PtS_2 , are definitely known, and the existence of various intermediate ones has been announced from time to time. PtS and PtS_2 are produced by acting upon solutions of corresponding platinum compounds with sulphuretted hydrogen. Both sulphides are black powders, PtS_2 must be dried without access of air as it readily undergoes oxidation.

Platinum cyanide, $Pt(CN)_4$, is best produced by precipitating a solution of potassium platinochloride, K_2PtCl_6 , with mercuric cyanide. It is of importance as it combines with cyanides of the alkali and alkaline-earth metals to produce a series of salts known as platino-cyanides which are remarkable for their wonderful colours and for their use in radiography. They are derived from platino-cyanic acid, $H_2Pt(CN)_4$, which can be prepared by decomposing the mercury or copper salt with sulphuretted hydrogen. The acid crystallizes from water in deliquescent prisms but is better crystallized from an ether-alcohol mixture. Potassium platino-cyanide, $K_2Pt(CN)_4 \cdot 3H_2O$, is easily produced by dissolving spongy platinum in a solution of potassium cyanide, preferably in the presence of air, or by the interaction of a solution of platinumous chloride with excess of potassium cyanide; in the latter method recrystallization is necessary to remove the potassium chloride simultaneously produced. It crystallizes in rhombic prisms which are yellow by transmitted light but have a blue metallic lustre by reflected light. The magnesium salt, $MgPt(CN)_4 \cdot 7H_2O$, crystallizes in beautiful red tetragonal prisms with metallic moss-green reflex. Its solution in water is colourless. Barium platino-cyanide, $BaPt(CN)_4 \cdot 4H_2O$, is the compound used for X-ray screens. It occurs in citron-yellow monoclinic prisms with a green reflex.

Platinum salts combine with ammonia in various proportions to form two series of bases, platinumous and platinum amines (see AMMINES). In the platinumous series there are two compounds having the formula $PtCl_4 \cdot 2NH_3$, they are probably cis- and trans-isomerides. A polymethylene having the formula $(Pt_4 \cdot 4NH_3)_4$ $PtCl_4$ has long been known as the "green salt of Magnus," and is made by the action of ammonia upon platinumous chloride. These compounds, although of great interest theoretically, are of little practical value. A complete account of these interesting compounds may be found in Gmelin-Kraut's *Handbuch*. (F. E. M.)

See L. Duparc and M. N. Tikhonovich, *Le Platine et les sels platineux* (de Pourcel et du Monde (1920); C. Jann, *World's Outlook for Platinum* (1928).

PLATINUM METALS. Although generally found in nature in the metallic condition, native platinum is never chemically pure. With it in varying proportions five other metals are generally associated, and to this group of six elements the name

"platinum metals" has been given. The six metals in the order of their atomic numbers and weights are as follows—

Metal	Sym.	Atom- wt.	Atom- wt.	Metal	Sym.	Atom- wt.	Atom- wt.
Ruthenium	Ru	44	101.7	Osmium	Os	76	196.8
Rhodium	Rh	45	102.91	Iridium	Ir	77	193.1
Palladium	Pd	46	106.7	Platinum	Pt	78	195.23

Although certain properties are common to the whole group, yet very great chemical and physical differences are found between the various members. It will be noticed that the atomic numbers of the first three and second three members are consecutive and that a common difference of 32 separates them. This common difference in atomic number corresponds to similarity in chemical properties between members differing by this constant number, at the same time similarities, more especially physical, are noticed amongst the members of each group.

One property common to the whole of the platinum metals is the high temperature of their melting points. The most easily fusible of them, palladium, only assumes the liquid condition at about $1,550^{\circ}\text{C}$, platinum comes next with a melting point of about $1,750^{\circ}\text{C}$ and the other metals fuse at temperatures intermediate between these and the melting point of osmium, which is about $2,700^{\circ}\text{C}$. Another property common to this group of metals is the valuable one of resisting chemical action and especially oxidation (the particular cases of ruthenium and osmium as regards oxidation will be dealt with when those metals are considered in detail).

Another property common to all members of the group is their great catalytic action, that is, the power of bringing about chemical action between other substances without themselves undergoing any alteration. In small chemical operations platinum and palladium are extensively used, but for large-scale or commercial working these metals, on account of their high cost, are not suitable unless the wastage is very small or negligible. Thus platinum and palladium are most efficient catalysts in the hydrogenation of oils and fats for the production of edible glycerides (*q.v.*), they are, however, seldom used for this purpose since the inevitable wastage would cause the process to be too costly. Metallic nickel or certain of its compounds are used instead, with the result that the operation has to be carried out at a considerably higher temperature, resulting in the destruction of some of the important vitamins which would have survived had palladium been used instead of nickel.

As regards density or specific gravity, the platinum metals resolve themselves naturally into two groups—the three members of lowest atomic weight have specific gravities of 11–12, *i.e.*, somewhat higher than, but not far removed from, that of silver, 10–11, the three higher members, however, are much denser and their specific gravities range from 21.4 for platinum to 22.5 for osmium which is the heaviest massive substance known under terrestrial conditions. As the specific gravity of platinum is near to that of gold, 19.4, an alloy of platinum with some base metal is easily prepared possessing the same density as gold.

Being bad conductors of electricity, platinum and its allied metals in the form of wire easily become incandescent when an electric current is passed through them. Incandescent lamps with very luminous filaments for electric lighting could be made without any danger of fusing of these metals. The first practical success was attained with filaments of metallic osmium, which was found to glow more vigorously and thus give better illumination than the other platinum metals. This fact is perpetuated in the name "Osram" which is still a trade-mark of certain lamp manufacturers, although the use of osmium for this purpose has long been discontinued. Although the platinum filaments for lamps were soon displaced by tantalum and tungsten, yet for a considerable time platinum entered into their construction, as some material had to be used, which could be fused into the glass without cracking, to carry the necessary leading-in wires. The only suitable substance then known was platinum, which has a coefficient of expansion almost the same as that of glass, and for a considerable time this was the only available material. This wasteful use of platinum has now been obviated by the production

of alloys of much cheaper material having the same coefficient of expansion as ordinary glass.

Occurrence.—The platinum metals appear to be widely distributed in nature, although generally in very small quantities. Localities in which they occur are Brazil, Colombia, Peru, Russia, Australia, Borneo, Tasmania, California and South Africa. Alluvial deposits have hitherto been the usual sources, but platiniferous reefs have now been found in the Transvaal and Natal. Alluvial platinum was reported in 1927 from Sierra Leone where an area of 40sq miles. The first definite recognition of crude platinum as a separate metal occurs in the 18th century, when chemists obtained samples of platinum ore from Cartagena.

In 1803 and 1804 four new metals were obtained from platinum. Osmium and iridium were discovered and isolated by Smithson Tennant and palladium and rhodium by W. H. Wollaston. The remaining platinum metal, ruthenium, was not discovered till 1828 when Osann succeeded in isolating it from the platiniferous ore of the Ural mountains, a deposit discovered in 1819. The platinum ores obtained from various localities differ greatly in composition. Platinum is generally found as the chief metal and the other metals of the group occur in relatively small and variable quantities. Occasionally, however, and especially in Australia and South Africa, small nuggets or grains of osmiridium are found, and recently considerable amounts have been found in Tasmania which is now its chief source. This mineral consists chiefly of the metals osmium and iridium, and also usually of a certain amount of ruthenium, the other platinum metals occurring to a small extent only. In addition to the six platinum metals, platinum ores contain other elements, the most common being gold, copper, silver, iron, chromium and nickel.

Separation.—The methods in general use for the separation of the six platinum metals are here outlined, detailed accounts of their purification being shown under the headings of the several metals. A platinum ore which has been freed from base metals and other impurities is treated with aqua regia (*q.v.*), osmium, most of the iridium and a small amount of ruthenium remain undissolved. The solution, containing platinum, palladium, rhodium and small amounts of ruthenium and iridium, is evaporated to dryness, when the metals are obtained as chlorides. These chlorides are then heated to about 150°C whereby the chlorides of palladium and iridium are partly decomposed giving lower chlorides. The residual mass is dissolved in very dilute hydrochloric acid, and ammonium chloride is added to precipitate most of the platinum and iridium as double chlorides, the other metals remaining in solution. This solution is then treated with metallic iron (technically termed "footing"), which throws all the metals completely out of solution; this precipitate, like all others similarly obtained, is technically called "foots". The precipitate after thorough washing is again dissolved in aqua regia, the solution is concentrated and again treated with ammonium chloride to remove further amounts of platinum and iridium and then treated with ammonium hydrate, when nearly all the palladium is thrown out as a difficultly soluble ammine, $\text{Pd}(\text{NH}_3)_4\text{Cl}_2$. The solution now containing rhodium and ruthenium is evaporated to dryness and strongly ignited, leaving the metals themselves. These are fused with potassium bisulphate, when the rhodium forms a soluble double sulphate leaving the ruthenium unattacked.

The foregoing residues containing osmium, iridium and some ruthenium are heated in a tube in a stream of air or preferably oxygen. Osmium and ruthenium form volatile oxides which are deposited in the cold parts of the tube. The residue, iridium with some ruthenium and small amounts of other platinum metals, is purified by suitable methods. A method of treating crude platinum ores, particularly useful in concentrating the platiniferous portion, is to heat the ores with metallic lead or to make a mixture of the ores with galena, scrap iron, glass and borax, the last two materials serving as a flux. The platinum metals, except most of the osmiridium, are dissolved in the lead which is removed by ordinary cupellation, the platinum metals remaining ready for subsequent treatment. In modern reef-mining, the platiniferous ores are concentrated after grinding by methods of oil flotation

Another method of opening up platinum ores is to treat a heated mixture of the substance and common salt with chlorine. All the platinum metals are attacked by this process giving double chlorides of the metal with sodium. As these double chlorides differ in stability, variations of the temperature of treatment give different products. Even if the double chloride is decomposed at or below the temperature of formation, the metal resulting from this decomposition remains in a finely divided condition and subsequent treatment is facilitated, and at the same time some of the stable double chlorides, especially that of iridium, are soluble in water and are easy to treat subsequently. It is obvious that with ores of different compositions some of the foregoing methods are more suitable than others in particular cases. Furthermore, all firms engaged in the refining of these metals have their own special secret methods. (F. E. M.)

PLATO (c. 428 B.C.—c. 348 B.C.), Greek philosopher, son of Ariston and Perictione, was born in the year 428–427 B.C. and died in 348–347 at the age of 80. His family was, on both sides, one of the most distinguished of Athens. Ariston is said to have traced his descent through Codrus to the god Poseidon; on the mother's side, the family, that was related to Solon, goes back to Dropides, archon of the year 644 B.C. Perictione apparently married as her second husband her uncle Pyrilampes (*Parm.* 126 C) a prominent supporter of Pericles, and Plato was probably chiefly brought up in his house. Critias and Charmides, leading men among the extremists of the reactionary Terror of 404, were respectively cousin and brother of Perictione; both were old friends of Socrates, and through them Plato must have known the philosopher from boyhood.

His own early ambitions as he tells us in the seventh *Epistle* (324 b–326 b) were political. The reactionaries urged him to enter public life under their auspices—at the age of 24—but he wisely held back till their policy should declare itself. He was soon repelled by their violence, particularly by their attempt to implicate Socrates in the illegal execution of their victim Leon. He hoped better things from the restored democracy, but its condemnation of Socrates finally convinced him that there was no place for a man of conscience in active politics. Hermodorus, an immediate disciple, is the authority for the statement that, on the execution of Socrates in 399 B.C., Plato and other Socratic men took temporary refuge with Euclides at Megara. The later *Lives* represent the next few years as spent in extensive travels in Greece, Egypt, Italy. Plato's own statement is only that he visited Italy and Sicily at the age of 40 and was disgusted by the gross sensuality of life there, but found a kindred spirit in Dion, brother-in-law of Dionysius I. of Syracuse.

The Academy.—About or soon after 387, Plato founded the Academy as an institute for the systematic pursuit of philosophical and scientific research. He presided over the society for the rest of his life, making it the recognized authority alike in mathematics and in jurisprudence. From the allusions of Aristotle we gather that Plato lectured without manuscript, and we know that "problems" were propounded for solution by the joint researches of students. On the political side there are traces of tension between the Academy and the rival school of Isocrates.

The one outstanding event in Plato's later life is his intervention in Syracusan politics. On the death of Dionysius I. in 367, Dion conceived the idea of bringing Plato to Syracuse as tutor to his successor, whose education had been neglected. Plato himself was not sanguine of results, but as both Dion and the philosopher-statesman Archytas of Tarentum thought the prospect promising, he felt bound in honour to risk the adventure. The project was by training Dionysius II. in severe science to fit him for the position of a constitutional king who might hold Carthaginian encroachment in Sicily at bay. The scheme was crushed by his natural jealousy of the stronger Dion, whom he drove into virtual banishment. Plato paid a second and longer visit to Syracuse in the year 361–360, in the hope of still effecting an accommodation, but failed, not without some personal danger. When Dion captured Syracuse by a coup-de-main in 357, Plato wrote him a short letter

of congratulation and warning against his own lack of tact and graciousness. After the murder of Dion in 354 the philosopher drew up the important seventh and eighth *Epistles*, reviewing and justifying the policy of Dion and himself and making proposals, unsuccessfully, for a conciliation of Sicilian parties.

The prejudice which led students in the 19th century to discredit the *Epistles*, in spite of the favourable opinion of scholars such as Bentley, Cobet, Grote, Blass, E. Meyer, worked havoc with their accounts of Plato's life. It is safe to say that at present the authenticity of the two letters of chief biographical importance, VII and VIII, is established. I and perhaps XII are admittedly unauthentic, on the rest opinion is divided. It seems to be inclining (rightly, as the present writer thinks), in favour of acceptance. The best recent account of the events in Sicily is in E. Meyer, *Geschichte des Altertums*, vol. 5.

To us Plato naturally is important primarily as the greatest of philosophical writers, but to himself the foundation and organization of the Academy must have appeared his chief "work." In the seventh *Epistle* he utters on his own account the same comparatively unfavourable verdict on written works, in contrast with the contact of living minds, as a vehicle of "philosophy," which he ascribes to Socrates in the *Phaedrus* (Ep. VII 341 b–e, 344 c.) It can hardly be doubted that he regarded his dialogues as intended in the main to interest an educated outside world in the more serious and arduous labours of his "school."

All the most important mathematical work of the 4th century was done by friends or pupils of Plato. Theaetetus, the founder of solid geometry, was a member of the Academy, as were also the first students of the conic sections. Eudoxus of Cnidus, the author of the doctrine of proportion expounded in Euclid's *Elements*, inventor of the method of finding the areas and volumes of curvilinear figures by exhaustion, and propounder of the astronomical scheme of concentric spheres adopted and altered by Aristotle, removed his school from Cyzicus to Athens for the purpose of co-operation with Plato. Archytas, the inventor of mechanical science, was a friend and correspondent. The Academy is thus the connecting link between the mathematics of the 5th century Pythagoreans and those of the geometers and arithmeticians of Alexandria.

Science.—Nor were other sciences neglected. Speusippus, Plato's nephew and successor, was a voluminous writer on natural history; Aristotle's biological works have been shown to belong largely to the early period in his career immediately after Plato's death, before the breach between the younger philosopher and the Academy. The comic poets found matter for mirth in the attention of the school to botanical classification. The Academy was particularly active in jurisprudence and practical legislation. Plato sent Aristonymus to the Arcadians, Phormion to Elis, Menedemus to Pyrrhia. Eudoxus and Aristotle wrote laws for Cnidus and Stagirus.

"Alexander asked Xenocrates for advice about kingship; the man who was sent to Alexander by the Asiatic Greeks and did most to incite him to his war on the barbarians was Delius of Ephesus, an associate of Plato" (Plutarch, *against Colotes*, 1136 c–d.) The creation of the Academy as a permanent society for the prosecution of both exact and humane sciences was, in fact, the first establishment of a University.

Socrates.—The most important formative influence to which Plato's mind was exposed in youth and early manhood was that of Socrates. But it does not appear that Plato, whose first ambitions were political, belonged to the innermost circle of the old man's intimates, or regarded himself as a "disciple." In *Ep. VII* he is careful to speak of Socrates not as a "master" but as an older "friend" (*φίλος*) for whose character he had a profound respect, and has recorded his own absence (through indisposition) from the death-scene of the *Phaedo*. It would seem that his own vocation to philosophy only dawned on him afterwards, as he reflected on the moral to be learned from the treatment of Socrates by the democratic leaders. Aristotle incidentally ascribes to him an early familiarity with the Heraclitean Cratylus, a younger man than Socrates and apparently an admirer of the philosopher. This may be only Aristotle's inference from the existence of the dialogue

Cratylus It is more important to remember Plato's connection with Pyrilampes and Critias. Pyrilampes was a Periclean politician, and Critias was known as a democrat until his moral balance was upset by the collapse of the Periclean system in 404. Early upbringing in a family of Periclean politics having connection with Solon may explain why Plato's own estimate of democracy in the *Politicus* and *Laws* is much less unfavourable than that which he ascribes to Socrates in the *Gorgias* and *Republic*.

Beyond this, we can say only that Plato in early life must have been exposed to the same influences as his contemporaries. His early experiences covered the disastrous years of the Decellean War, the shattering of the Athenian Empire and the fierce civil strife of reactionaries and democrats in the year of anarchy 404-403. He was too young to have known anything by experience of the imperial democracy of Pericles and Cleon, or of the full tide of the "sophistic" movement. It is not from memory that he depicts Protagoras or even Alcibiades, as they were in their great days.

The Works.—The canon and text of Plato appears to have been fixed by two scholars, Dercylides and Thrasylus, either shortly before or shortly after the Christian era. Thrasylus is uncertainly identified with a grammarian of the name who flourished in the reign of Augustus and was "heard" by Tiberius. By reckoning the *Epistles* as one item, the list was made to consist of 36 works, arranged in nine "tetralogies," or groups of four (Aristophanes of Byzantium had already attempted an arrangement in "trilogies," or groups of three, which, however, he did not carry through).

Textual Problems.—No genuine work of Plato has been lost, but there is a general agreement of modern scholars to reject a number of small items from the text. Their verdict may be said to have gone definitely against the following, *Alcibiades I*, *Alcibiades II* (suspected by some even in ancient times), *Theages*, *Erastae*, *Critophan*, *Hipparchus*, *Minos*. Most or all of these are probably early Academic work, and possibly not all later in date than Plato's death. Most, though not all, contemporary scholars also regard the *Epinomus*—in the present writer's opinion wrongly—as an appendix to the *Laws* added *de suo* by the mathematician Philippus of Opus, who is recorded by Diogenes Laertius (III. 37) to have transcribed the work for circulation. The *Greater Hippias* and *Menexenus* are still regarded as doubtful by some, though Aristotle used both, and expressly quotes the latter, in a way which seems to prove that he regarded them as Platonic. (The wild negative criticism of German scholars of the middle of the 19th century, which received its death-blow in 1867 from L. Campbell's proof of the genuineness of *Sophistes* and *Politicus*, is now universally recognized to have been an aberration.) Plato's will, preserved by Diogenes (III. 41-43), is pretty certainly authentic. Some of the 32 epigrams ascribed to him in the *Anthology*, may conceivably be genuine.¹

Order of Dialogues.—Plato's literary career extended over the greater part of a long life. The *Apology* must have been written while the memory of Socrates' appearance before his judges was still fresh; the *Laws* is confessedly the work of an old man with a long experience of life behind him, and the state of its text fully bears out the tradition, preserved by Proclus, that its aged author never lived to give it final revision. Some half a century or more must have elapsed between Plato's last and his earliest composition.

This of itself would prove that Schleiermacher, with whom modern critical study of Plato begins, went astray in assuming that Plato started his career with a ready-made complete "system" to be disclosed. We must expect to find in his writings evidence of the development of his mind. But if we are to read the development aright we must have some trustworthy way of determining the order of the dialogues. Plato himself has only given us the

scantiest indications of the order. He has linked the *Sophistes* and *Politicus* externally with the *Theaetetus* as professed continuations of the conversation reported in that dialogue, he has also, as most students recognize, linked up the *Timaeus* in the same way with the *Republic*. Aristotle adds one other piece of information, that the *Laws* were written after the *Republic*. Further investigation of the problem opens in 1867 with L. Campbell's edition of the *Sophistes* and *Politicus*, and the work thus begun was continued by others, notably W. Dittenberger, C. Ritter and W. Lutoslawski.

By consideration of numerous independent stylistic criteria (for which see the works named at the end of this article), it has been definitely established that the dialogues *Sophistes*, *Politicus*, *Philebus*, *Timaeus* (with its fragmentary sequel *Critias*), *Laws*, form a distinct linguistic group, which must belong to the later years of Plato's life, as we might have presumed from the consideration that Socrates, the central figure of other dialogues, becomes, in those of this group (with a solitary exception for the *Philebus*, the one member of the group which is wholly preoccupied with ethics), a secondary personage, and disappears altogether from the *Laws*. The whole group must therefore be later than the *Sophistes*, which professes to be a sequel to the *Theaetetus*. Now the *Theaetetus* can be dated with some accuracy, since it commemorates the recent death of the eminent mathematician after whom it is named from disease and injury contracted in a campaign before Corinth, which, as elaborately proved by Eva Sachs (*de Theaeteto Atheniensis*, Berlin, 1914), must be that of 369 B.C. The dialogue may thus be safely ascribed to 368-367, the eve of Plato's departure for Syracuse, and the marked change of style visible in the *Sophistes* is best explained by the supposition that there was a break in Plato's literary activity during the years 367-360 when he was specially occupied with Sicilian affairs. So much may be regarded as fairly certain.

The Earlier Dialogues.—It is not so easy to reach definite conclusions about the order of composition of the more numerous earlier group of dialogues. It is generally recognized, on linguistic and other grounds, that the series ends with the *Theaetetus* and the closely related *Parmenides*. Attempts have been made by C. Ritter, Lutoslawski and others, to determine the internal order of the group on linguistic evidence, but there are obvious reasons for doubting whether the methods which have been successful in establishing the distinction between the two great groups of earlier and later dialogues can be applied with the same confidence to works belonging to the same general period of their author's life and composed probably at no great distance of time from one another.

In point of fact, there is not complete agreement between the arrangements proposed by different "stylisticists," and their advocates have usually eked out the strictly philological argument by more or less dubious assumptions about the development of Plato's thought, though it is very questionable whether any real development can be traced before the *Theaetetus* and *Parmenides*.² Perhaps all that can be said with certainty is that the great outstanding dialogues, *Symposium*, *Phaedo*, *Republic* (and the writer of this article would be inclined to add *Protagoras*), in which Plato's dramatic power is at its highest, mark the culmination of this first period of literary activity. The comparative decline of dramatic power, accompanied by compensating maturity of critical acumen is the most striking contrast between the dialogues of the second and those of the first period.³ A good account of the work done by the "stylisticists" will be found in H. Raeder, *Platon philosophische Entwicklung* (1905).

The Socrates of the Dialogues.—The great internal difficulty which besets the modern student of Platonic philosophy is that created by the dramatic form of Plato's writings. Since Plato

²See in particular the important study of P. Shorey, *The Unity of Plato's Thought* (1933).

³In *Ep. VII* 326a Plato seems to refer to *Rep. VI* 499 b-c as already written before his first visit to Sicily in 387. It has been argued that the *Symposium* must be later than 385 since Aristophanes, who died in that year, is introduced into the dialogue. But it is not clear that Plato made it an absolute rule never to introduce living speakers. It is hard e.g. to believe that Euclides must have died while the *Theaetetus* was being written.

¹The most dubious are also the best known. That on Agathon (imitated by Shelley, "Kissung Helena") and that on Alexis and Phaedrus are condemned by the occurrence of the names Agathon and Phaedrus. They are obviously suggested by the parts played by the tragic poet Agathon and Phaedrus of Myrrhinus in the *Symposium* and *Phaedrus*. The author has forgotten that both were grown men in Plato's childhood. This suggests suspicion of all the "amatory" verses. The syntax of the first of the epigrams on Aster is also singular.

never introduces himself into his own dialogues, he is not formally committed to anything which is taught in them. The speakers who are formally bound by the utterances of the dialogues are their protagonists, Socrates, Parmenides, the Pythagorean Timaeus, and all these are real historical persons. The question thus arises, with what right do we assume that Plato means us to accept as his own the doctrines put into the mouths of these characters? Is his purpose dogmatic and didactic, or may it be that it is mainly dramatic? Are we more at liberty to hold Plato responsible for what is said by his *dramatis personae* than we should be to treat a poet like Browning in the same fashion?

It is tempting to evade this formidable issue in one of two ways. One is that of Grote, who held that Plato allows himself freely to develop in a dialogue any view which interests him for the moment, without pledging himself to its truth or considering its compatibility with other positions assumed elsewhere in his writings. Thus, according to this theory, Plato can make Socrates advocate hedonistic utilitarianism in the *Protagoras*, or denounce it in the *Gorgias*, can assert the so-called "ideal theory" through the mouth of Socrates in the *Phaedo*, or refute it in the character of Parmenides in the dialogue of that name, with equal gusto and without pledging himself in either case. His championships are purely dramatic, or, at most, reflect his passing mood at the moment of composition.

The more common assumption of the 19th century was that some of Plato's characters, notably Socrates and Timaeus, are "mouthpieces" through whom he inculcates tenets of his own, without concern for dramatic or historical propriety. Thus it was, and often still is, held that the most famous philosophical doctrines of the *Phaedo* and *Republic*, the "ideal theory," the doctrine of "recollection" and of the tripartite soul, were actually originated by Plato after the death of Socrates, to whom these speculations were entirely unknown, and consciously fathered on the older philosopher by a mystification too glaring to deceive any one seriously. Careful study of the dialogues should satisfy us that neither of these two extreme views is tenable.

The Thought of the Earlier and Later Dialogues.—There is undeniably a real difference between the thought of the dialogues which are later than the *Theaetetus* and those which are earlier, and this difference will have to be accounted for. But there are no serious discrepancies of doctrine between the individual dialogues of the same period.¹

Now Plato seems to announce his own personal conviction of certain doctrines of the second group of dialogues by a striking dramatic device. In the *Sophistes* and *Politicus* the leading part is taken by an Eleatic and in the *Laws* by an Athenian who are the only anonymous, indeed almost certainly the only imaginary, personages in the whole of Plato's writings.² It can hardly be doubted that the reason why these two characters have been left anonymous is precisely that the writer may be free to use them as "mouth-pieces" for his own teaching. Plato thus takes on himself the responsibility for the logic and epistemology of the *Sophistes* and *Politicus* and the ethics and educational and political theory of the *Politicus* and *Laws* in a specially marked way, and by doing so compels us to face the question how far he means the utterances of Socrates in his earlier dialogues to be taken as expressions of a philosophy of his own.

"Forms."—It may be regarded as an established result of the inquiries of Dr. Henry Jackson and others that there is a definite philosophical doctrine running through the earlier dialogues which has as its main features the theory of "Forms" (the "ideal" theory), the theory that knowledge is "recollection," and the theory of the "tripartite soul." In the dialogues of the second period these tenets, as we have learned to know them from the earlier

dialogues, appear only in the mouth of Timaeus, a 5th century Pythagorean older than Socrates, and the most important of them all, the theory of "Forms" is actually made the object of what looks like a refutation in the *Parmenides*.

The problem is to find an explanation of this puzzling fact. Are we, with Dr. Jackson³ and others to distinguish two philosophies, both originated by Plato after the death of Socrates, an earlier and a later? Or are we to suppose that in the main the object of the first group of Plato's dialogues is to preserve the memory of Socrates and that the philosophy expounded is in the main what it professes to be, the thought of Socrates, coloured, no doubt, unconsciously but not consciously distorted, in its passage through the mind of Plato? On the second view we should have to say that, strictly speaking, Plato had no distinctive Platonic philosophy until a late period in his life, much as we can say that, though Kant was all through his life a prolific writer on philosophy, there was no distinctive Kantian philosophy before the *Critique of Pure Reason*. Most Platonic scholars are still unwilling to accept this interpretation of the facts, though there are weighty considerations which plead strongly for it.

Socrates and Plato.—It is significant that the only dialogue not earlier than the *Theaetetus* in which Socrates takes a leading part is the *Philebus*, the one member of the second group which deals exclusively with those ethical problems on which the thought of the historical Socrates had been specially concentrated. This is most naturally explained by supposing that Plato, from regard to fact, was unwilling to make Socrates the exponent of doctrines which he knew to be his own property, though it is hard to understand his misgivings if he had already for years been employing him in that very capacity.⁴ (If, as is most probable, *Ep. II* is authentic, the question would be definitely settled by the sentence of the latter [314 c] "there is not, and never will be, a work of Plato, the works which now go by that name belong to Socrates embellished and rejuvenated.")

It is notable, too, that Aristotle apparently knew nothing of an earlier and a later version of Platonism. He attributes a definite doctrine to Plato which is quite unlike anything to be found in the first great group of dialogues, and seems to be known to him from oral communications in the Academy, though something like it can, by looking hard, be read between the lines in the *Philebus*. It was also the view of Neo-Platonic scholars like Proclus that the "ideal theory" expounded in the great earlier dialogues really originated with Socrates and that something of the same kind was also held by contemporary Pythagoreans in Italy (Proclus in *Parmenidem* ed. Stallbaum 562, 610), and the fact that Proclus does not find it necessary to argue the point seems to show that this had been the standing tradition of the Academy. Similarly Galen, in the early 3rd century of our era, has preserved the definite statement of the learned Stoic Poseidonius that the doctrine of the "tripartite soul," often said in modern times to be another invention of Plato's, is as old as Pythagoras (Galen de *placit. Hipp. et Plat.* 425, 478).

Moreover, as Burnet has argued, it is very hard to believe that any writer would introduce a far-reaching novel speculation of his own to the world in the curious fashion which Plato is supposed to have adopted in the *Phaedo*, where Socrates is made to describe the "ideal theory" as something quite familiar which he has for years constantly canvassed with his intimates (nearly all, if not all, of whom, were certainly living when the *Phaedo* was circulated). It is not necessary here to determine the historical question. We may be content to turn to the Platonic dialogues, carefully distinguishing the successors of the *Theaetetus* from its predecessors, and attempt a summary of their contents. The general doctrine of the first period will be described without any more or less arbitrary attempt to say how much of it may be actually "Socratic." We may then consider how far this doctrine is modi-

¹As there would be between the *Protagoras* and the *Gorgias* or *Phaedo* if the *Protagoras* really said that the pleasure is the good. What it actually says is only that "the many," "most men," hold this view (353 d-e), and ought not therefore to regard the doctrine that "goodness is knowledge" as paradoxical, since on their own theory, virtue will amount to right computation of pleasures and pains.

²Except the two minor personages of the *Laws*, a Spartan and a Cretan, who have really nothing to do except to say "Yes," "No," in the appropriate places.

³*Journal of Philosophy* X—XII.

⁴It might be said that if the principal doctrines of the Platonic Socrates were known by Plato to be his own peculiar property, he might feel a difficulty about putting a new and more critical philosophy into the mouth of the speaker who had been used as the exponent of his "earlier" teaching. But this would not wholly explain why Socrates might not have been made to teach the logic of the *Sophistes*.

fied in later dialogues, or in the version of Platonism presupposed by Aristotle's criticisms.

No attempt will be made here to describe the personality or temperament of Plato which is, in fact, as elusive as that of Shakespeare and for the same reason. He is often credited with a strongly "mystical" and "erotic" temperament. He does ascribe such a temperament to Socrates, but it is puerile to treat his picture of Socrates as evidence about himself, though the mistake is constantly committed.

It should therefore be noted that the "mysticism" is confined to dialogues of the first period, in which Socrates is its exponent, and that the "erotic" language in which Plato's Socrates speaks of his devotion to his young friends was also used by the Socrates of Aeschines to describe his relations with Alcibiades (Fr. 4, Krauss). There is no evidence that Plato personally ever fired the imagination of gifted boys as Socrates did. Apart from the *Epistles*, the most valuable light we possess on Plato's personality is afforded by Aristotle's description of him as a man "whom it is blasphemy in the base even to praise" (*ὅν οὐδ' αὖτε τοῖσι κακοῖσι θεῖται*).

THE EARLIER DIALOGUES

In the *Republic*, the greatest of all the dialogues which precede the *Theaetetus*, there may be said to be three main strands of argument deftly combined into a consummate artistic whole, the ethical and political, the aesthetic and "mystical," and the metaphysical. Other major dialogues belonging to this period give special prominence to some one of these three lines of thought, the *Phaedo* to the metaphysical theme, the *Protagoras* and *Gorgias* to the ethical and political, the *Symposium* and *Phaedrus* to the aesthetic and "mystical," though in none does Plato make an artificially rigid separation of any one of the great ideal interests of human life from the rest.

The shorter dialogues deal with more special problems, usually of an ethical character, and mostly conform to a common type. A problem in moral science, often that of the right definition of a "virtue," is propounded, a number of tentative solutions are considered and are all found to be vitiated by difficulties which we cannot dispel, we are thus left, at the end of the conversation, aware of our discreditable ignorance of the very things it is most imperative for man to know. We have formally "learned" nothing, but have been made alive to the worthlessness of what we had hitherto been content to take for knowledge and the need of seeking further enlightenment.

The effect of these "dialogues of search" is thus to put us in tune with the spirit of Socrates, who had said that the one respect in which he was wiser than other men was just his keen realization of his own ignorance of the most important matters. We learn the meaning of his ruling principle that the supreme business of life is to "tend" the soul (to "make it as good as possible") and his conviction that "goodness of soul" means first and foremost, knowledge of good and evil. The three dialogues directly concerned with the trial of Socrates have manifestly a further purpose. They are intended to explain to a puzzled public why Socrates thought it stuff of the conscience neither to withdraw from danger before trial, nor to make a conciliatory defence, nor, finally, to avail himself of the opportunity of flight after conviction. Even well-wishers like Xenophon, as we know, were puzzled by what had seemed his wilfully defiant attitude, it was therefore a debt of honour to his memory to put the matter in the true light. In the remarks which follow, we will consider these shorter dialogues in an order adopted simply for purposes of convenience.

Hippias I. and II.—In these dialogues Socrates has as "respondent" the well-known polymath Hippias of Elis, whose self-complacency is sharply satirized. In the *Hippias Minor* the question propounded is "What is the fine" (*καλόν*)? "Fine" is a predicate by which we are constantly expressing both aesthetic and moral approval, do we really know what we mean by it? We discover that we do not, though incidentally we also learn that "fine" or "beautiful" is certainly not a synonym for either "useful" or "pleasant." *Hippias Minor* deals directly with the famous Socratic paradox that "wrong-doing is involuntary." It

is commonly held that it is much worse to tell a wilful untruth than to blunder into an unintentional false statement. Yet the analogy of the arts and professions seems to show that the man who errs intentionally, if there is such a person, is a better man than he who errs unintentionally. (The suggested thought, of course, is that there "is no such person." The man who knows what is good will always aim at this and at nothing else,—the familiar doctrine of Socrates.)

Ion, Menexenus.—Both these are "occasional" works. Socrates had said that he found the poets, who as a class are commonly reckoned "wise," quite unable to explain to him how they came to say their best things, or what they meant by them (*Apol.* 22 a-c). The *Ion* develops this thought into the theory that neither the poet, nor his interpreter the "thapsode," produces his effects "by science," *i.e.*, as a result of conscious "artistry," the effect in both cases is due to a non-rational "inspiration," or, as we now say, "native genius." (The importance of this is that it rules out appeal to the poets as specially competent authorities on the conduct of life.)

The *Menexenus*, which professes to repeat a "funeral oration" learned from the famous Aspasia, is apparently meant as a satire on "patriotic" distortion of history. Apparently the "discourses" satirized are those of Pericles in Thucydides, Lysias (Lysias II) and Isocrates (the *Panegyricus*). The singular anachronism by which Socrates (and Aspasia) are represented as commenting on the events of the Corinthian War down to the year 387 must be intentional, whatever its object.

Charmides, Laches, Lysis.—These are typical "dialogues of search." The question of the *Charmides*, which contains a particularly delightful picture of the way of Socrates with a promising lad, is what is meant by *sophrosyne*, the virtue which is shown alike in graceful and easy command of one's appetites and passions, in dutiful behaviour to parents, elders, official "superiors," in balance and sanity amid the ups and downs of fortune. We seem to be in a fair way to identify this virtue with "knowledge of self"—the self-knowledge Socrates had valued so highly—when we are confronted with an ambiguity. "Self-knowledge" might be taken to mean a knowledge which has knowledge itself for its object, in fact for "epistemology." But it is hard to be sure that there is any such science as "the knowledge of knowledge," and harder still to see how such knowledge could be directive of conduct.

In the *Laches* we are concerned with valour, the soldier's virtue. Here again we are on the point of defining the virtue as knowledge of what is and what is not really to be dreaded. But this is tantamount to saying the true knowledge of evil and good, and the resultant definition, "valour is knowledge of good" would identify valour with the whole "goodness of man." That is, the definition is only possible if we can meet the popular objections to the Socratic thesis of the "unity of virtue."

The *Lysis* examines in the same tentative way, friendship, the relation in which self-forgetting devotion most conspicuously displays itself. The crux of the problem is that after many false starts, we seem to have reached a promising result in the view that each friend is really "a part of" the other in "soul or temper or body," and yet it is hard to reconcile this position with the facts which seem to show that "unlikeness" is a potent source of attraction. Aristotle has taken up and discussed the issues raised in the dialogue in his own treatment of the same subject (*EN* VIII-IX).

Cratylus.—The question here, one much agitated in the age of Socrates, is whether names are significant by "nature" or "convention." Is there some special appropriateness of the sounds or names to the objects called by them, or is there no bond between the thing and its name but that of the "usage of the community"? The absurdity of attempts to get metaphysics out of etymologies is humorously exposed by showing that the method can be used at pleasure to prove either that the "giver of names" agreed with Heraclitus that motion is the sole reality or that he held, with Parmenides, that motion is an illusion. Yet there are real analogies between "vocal gestures" and the things signified by them, which are pointed out with a good deal of insight. The main purpose of Plato, however, is to dwell on the point that language

is an instrument of thought, the test of its rightness is not mere "social usage," but its capacity to express true thought accurately.

Euthydemus.—The dialogue is, in large part, broad satire on "eristics" who misapply the logic of Zeno for the purpose of entangling anyone who commits himself to any assertion in fallacies due to the ambiguity of language (Aristotle has drawn freely upon it in his own essay on Fallacies, the *de Sophisticis Elenchis*). Its more serious purpose is to contrast this futile contradiction-mongering with the "protreptic" of Socrates. The lad Clinias is simply bewildered by the questions of the two professors of "eristic"; those of Socrates have the purpose of convincing him that the happiness we all desire is not guaranteed by the possession of the things the world accounts good, but depends on our making the right use of them. If we would attain happiness we must "tend" our "souls," and that means that we must acquire the "royal" science which ensures that we shall make the right use of all the gifts of mind, body and fortune, in other words, the knowledge of true and absolute good.

Gorgias.—The *Gorgias* is a much greater, as well as a much longer work than any of those we have considered, and has always been a prime favourite with serious moralists. Beginning ostensibly as an enquiry into the nature and worth of "rhetoric," the art of advocacy professed by Gorgias, it develops into a plea of sustained eloquence and logical power for absolute right, as against expediency, as the sovereign rule of life private and public, and ends with an imaginative picture, on Orphic lines, of the eternal destinies of the righteous and the unrighteous soul. Literature has no more impressive presentation of the claim of conscience to unqualified obedience and the impossibility of divorcing the politically from the morally right.

Gorgias holds that "rhetoric" is an "art," the application of knowledge to practice, and the queen of all "arts," since it gives its possessor the object of man's highest ambition, power to enforce his will on society. The statesman, who is the power of men, is just a consummate advocate speaking from a brief. If he is clever enough he will, though a layman, carry the day with an audience of laymen, even against the expert specialist. To his audience he will seem, though he is not, the superior of the real expert. Socrates declares that "rhetoric" is not an "art," a matter of native principles, but a mere "empiric knack" (*τεχνη*) of humoring the prejudices and pleasing the tastes of an audience. It is a subspecies of *κολακεια*, "parasitism."

There are two genuine "arts" conducive to the health of the body, those of the trainer and the physician; each has its parasitic counterfeit, the one in the profession of the "beautifier," the other in that of the confectioner. So there are two "arts" conducive to "health of soul," those of the legislator, who lays down the rule of morally sane life, and of the judge, who corrects moral disorders. The "sophist" counterfeits the first, as the "rhetorician" the second, by taking the "pleasant" instead of the "good" as his standard. The "rhetorician" is thus not the wise physician of the body politic but its "toady" (*κόλαξ*). This severe judgment is disputed by Polus, the ardent admirer of Gorgias, on the ground that the successful "rhetorician" is virtually the autocrat of the community, every man's life and property are at his mercy.

To be such an autocrat is the summit of human happiness; even if, like Archelaus of Macedonia, the aspirant only reaches the position by a series of shocking crimes, he is the most enviable of mankind, because he is above law and can do "whatever he likes." Socrates denies this. The autocrat always does "as he pleases," and for that reason never does "what he wishes," like all mankind, he wishes for true happiness or good, but no act which is immoral ("unjust") ever leads to happiness. To suffer a wrong is an evil, but to inflict one is much worse. And if a man has committed a wrong, it is much worse for him to go unpunished than to be cured of his moral malady by the sharp but wholesome medicine of punishment. If "rhetoric" is of real service to men, it should be most of all serviceable to an offender. If he knew his own interest, he would employ all his powers of persuasion to move the authorities to inflict the penalties for which the state of his soul calls. Polus is unable to meet this

reasoning, because he had at least conceded to current morality that it is more disgraceful, though not more evil to inflict wrong than to suffer it.

This is denied by Calicles of Acharnae, an otherwise unknown politician, who proceeds recklessly to develop the doctrine of the "will to power." It may be a convention of the herd that unscrupulous aggression is creditable and wrong, but "nature's convention" (the *νόμος τῆς φύσεως*, a phrase which appears here for the first time in literature) is that the strong are justified in using their strength as they please, while the weak "go to the wall." Calicles and Socrates thus appear as champions of two contrasted moralities of private and public life. Calicles stands for self-assertion in ethics and aggressive "Imperialism" in politics. Socrates opposes both. In his judgment the creators of the imperialistic Athenian democracy were no true statesmen, because they were content to give Athens a navy and a commerce without creating a morally sound national character. They may have been capable "domestic servants" of the democracy for whose tastes they catered, they were not its physicians. The one true statesman of the past was the "just" Aristides, in the present, Socrates himself is the one man who shows a statesman-like mind, though it is perfectly true that he might at any moment have to pay with his life for refusing to call that good which pleases the public fancy. It is not true, as Calicles supposes it to be, that the secret of happiness is to have strong and vehement passions and be able to gratify them to the full. That would be a condition like that of the fabled sinners who are punished in Hades by being set to spend eternity in filling leaking pitchers. The truly happy life is that of "measure" in which the gratification of desire is strictly regulated by regard for justice and *sophrosyne*. If we may believe the Orphic doctrine of judgment to come, the votary of "passion" and injustice has a heavy reckoning to await hereafter.

Meno.—The *Meno* is nominally concerned with the question what virtue is and whether it can be taught, but it is further interesting for two reasons. It states clearly the doctrine, which we have not met so far, that knowledge is "recollection"; it also introduces as a character the democratic politician, Anytus, the main author of the prosecution of Socrates. It seems plain that Plato wishes to indicate his opinion that it was Socrates' severe criticism of the great figures of the history of Athenian democracy which led to the prosecution.

Can virtue be taught or learned (as must be the case, if the professional sophists can really do what they profess)? That depends on what virtue is. We are on the way to define it as "ability to secure good things by honest means," when we reflect that honesty itself is a "good thing," and the definition consequently is circular. This reminds us of the current dilemma that all such inquiries are futile because it is idle to inquire into what you already know, useless to inquire into what you do not know (since you could not recognize the unknown, even if you found it). This difficulty would vanish if it were true that the soul is immortal and has long ago learned all truth, so that it needs now only to be "reminded" by sense-experiences of truths it once knew and has forgotten. This (Orphic) doctrine seems to be supported by the experience that a lad who has never studied geometry can be brought to recognize mathematical truths by merely showing him a diagram and asking him appropriate questions about it. He produces the right answer "out of himself." (The point thus is the presence of an *a priori* element in mathematical truth.)

In any case, we may say that if "virtue" is knowledge, it can be taught; if it is not knowledge, it cannot. But is it knowledge? If it is, one would suppose that there must be professional teachers of it. But Anytus assures us vehemently that the sophists, who claim to be such professionals, are mischievous impostors, and we can be sure that the ordinary decent citizen cannot "teach virtue," as Anytus maintains, since the "best men" of the democracy, Themistocles and the rest, have been unable to teach it to their own sons. Perhaps, then, we must say that the "best men" of Athens have no genuine knowledge of good, their successes have been due not to knowledge, but to

mere "correct opinions." Still, for practical purposes a correct opinion will serve as well as knowledge. The trouble is that you cannot depend on its permanency unless you fasten it down by thinking out the reason why of it (*αἰτίας λογισμῷ*). Then it becomes knowledge. If a man should arise who could actually teach statesmanship to others, he would be one who really *knew* what good is, the virtue of such a scientific statesman would be to that of other men as substance is to shadow.

Protagoras.—This finely dramatic dialogue gives us the completest presentation to be found in Plato of the main principles of the Socratic morality, and is the direct source of Aristotle's statements about the teaching of Socrates in the *Nicomachean Ethics*.

Socrates meets, in the house of Callias, the eminent sophist Protagoras, who is very attractively drawn and represented as a great admirer of the younger man's ability. Protagoras explains that his profession is the "teaching of goodness," and that by "goodness" he means the art of making a success of one's own life, that of one's household and that of one's "city" (Thus he teaches "the conduct of life, private and public," and has done so for years with success.) Socrates urges that there are two considerations which make it look doubtful whether this art can be taught. The Athenians have a high reputation for intelligence, but it is notorious that the Ecclesia requires no evidence of expert knowledge in a speaker who discusses the morality of a proposed course of action.

Also the eminent democratic statesmen have never taught their own "goodness" to their sons. Public opinion and the practice of the eminent few alike suggest that the "conduct of life" is not teachable. Protagoras, to be sure, thinks that the absence of special teachers only proves that every citizen of a civilized city can, in his degree, act as teacher, exactly as he can teach his children his native language or his trade. Goodness depends on *δίκη* and *αἰδώς*, the sense of right and conscience, and the whole of life in a civilized society, is a process of education in these. His exposition at once raises the problem of the unity of virtue. Are the various commonly recognized "virtues" really different, so that a man may be strong in one but weak in another? Protagoras is at first inclined to say that they are, but on reconsideration is ready to identify all of them but one with wisdom or sound judgment.

An exception must be made for courage, a virtue which is popularly regarded as having something conspicuously non-rational about it. The dialogue culminates in an argument by which Socrates attempts to show that there is no need to make this exception. The general public, the party which insists so much on the non-rational character of courage, would be ready to accept the identification of the good and the pleasant, and to grant that the goodness of courage means that by facing pain and danger one escapes worse pain or danger. On their own theory, then, courage, and the rest of virtue, can be reduced to prudent computation of pleasures and pains. The humour of the situation is that Socrates and Protagoras have thus changed places. Socrates, who had raised a difficulty about the teachability of virtue, is left satisfied that virtue must be knowledge, Protagoras, who claimed to be able to teach it, ends by declaring that, whatever virtue may be, it cannot be knowledge. It is important to observe that the dialogue does not teach Hedonism. The equation good=pleasant is advanced only as one which would be accepted by "the mass of men," and should forbid them to find a paradox in the identification of virtue with knowledge, it is expressly repudiated by Protagoras as unworthy of a man of high character.

All that Socrates asserts is that virtue is knowledge and wrongdoing consequently involuntary. There is no disagreement in moral principle between the *Protagoras* and the *Phaedo* or *Gorgias*. If the "mass of men" are ready to accept the Hedonist formula, that is because they are votaries of the body-loving life (*βίος φιλοσώματος*); this is why we are told in the *Phaedo* that "popular" virtue is illusory. The true explanation of Socrates' doubts is that though he holds that true virtue, being knowledge, is teachable, he does not believe that what Protagoras

is trying to teach is true virtue. "Success" depends on personal "tact" and "tact" cannot be learned from an instructor.

Euthyphro, Apology, Crito.—The main purpose of these three works, which deal with the bearing of Socrates before, during and after his trial, is to obviate possible serious misunderstandings of the Master's position and motives, the theme of all three may be said to be the true meaning and importance of "care" or "tendence" of the soul.

The problem of the *Euthyphro* is what is religion (*τὸ δέον*). The respondent Euthyphron is certainly meant to be a kind of Orphic sectary, not, as has been fancied, a representative of ordinary Athenian belief and practice. Socrates had associated with such men and was known to hold unusual beliefs about the soul, hence it was important to make it plain that he was something different from a fanatic. The dialogue, interesting also from its well-developed logical terminology, enables Socrates to repudiate immoral mythology and to reject the conception of "religious duty" as fulfillment of purely arbitrary commands. Its central thought, which, however, is not formally asserted as a conclusion, is that the "service" (*θεράτεια*) of God which is religion means co-operation with God and under God in the production of a "noble soul" (*πάγκαλον ἔργον*), the nature of which is not further defined, though it is sufficiently clear that the "work" meant is the "tendence of the soul."

Consideration of the *Apology* and *Crito* in detail belongs rather to the study of Socrates (*qv*) than to that of Plato. Of the *Apology* we must be content to say here that the real defence of Socrates is contained in the pages which explain that the main-spring of his life has been his conviction that he has a mission from God to spend his life in "philosophy," the endeavour to "make his own soul as good as possible," and to incite mankind to do the same, to this mission it is his duty to be strictly faithful, even if faithfulness means condemnation as a traitor by the democracy. The *Apology* thus depicts Socrates as carrying out in his own practice the ethical programme of the *Gorgias*. The actual accusation is treated with contempt and satirical humour (See article SOCRATES).

The point of the *Crito*, though simple, is often missed. Was Socrates wantonly throwing away a valuable life by refusing to escape from prison? Why did he make this refusal? Because, though the conviction was materially iniquitous, it was the verdict of a legitimate court, which could not be disregarded without real disloyalty. Socrates has been wronged not by the law, but by politicians who have abused the law. If he disregarded the conviction, he would be directly doing a wrong against the whole social system.

Foundation of Plato's Doctrine.—In the works so far considered we have the foundation of a moral and political doctrine based on Socratic principles, from which Plato never departed. The main underlying thought is that the great concern of man, a concern not limited to this earthly life, is the development of a rational moral personality (the "tendence of the soul"). Our felicity depends wholly on our success in this task (to use Butler's language, on "our conduct," not on "our condition"). And this success, again, depends on rational insight into the true scale of good. Men do not miss felicity because they do not desire it, on the contrary no man ever really desires anything else. The reason why men forfeit felicity is that they mistake apparent good for real, the conditionally for the absolutely good. If a man ever knew with assurance what absolute good is, he would in practice never pursue anything else. It is in this sense that "all virtue is knowledge" and that "all wrong-doing is involuntary" (*εἴ*, consists in the pursuit of what is falsely supposed to be good).

"Popular morality" is confused in theory and unreliable in practice because it does not rest on any assured insight into absolute good, "philosophic morality," just because it does rest on such certain insight, is a morality of absolute and unconditional obedience to conscience, such as Socrates had shown. Since the task of the statesman is simply the task of "tending the soul" extended to the "national" soul as its object, the "philosophical" moralist is also the only true statesman. True states-

manship means the promotion of national character as the one thing which matters and is therefore simply the application, on the grand scale, of the principles of absolute morality, what falls short of this is opportunism masquerading as statesmanship.

These convictions clearly imply a far-reaching metaphysic as their foundation and justification. The principles of this metaphysic, though they are frequently hinted at in passages of dialogues already reviewed, are put before us more explicitly in those we have now to consider, in connection with them we shall also observe an explicit theory of knowledge and scientific method.

Phaedo.—The *Phaedo* is often treated as though its object were to provide a demonstration of the immortality of the soul. It does not really profess to do this. The object is to justify faith in immortality as a rational faith by showing that it follows naturally from a fundamental metaphysical doctrine (the "ideal theory" or "doctrine of Forms"), which seems to afford a rational clue to the structure of the universe, though it is expressly said at the end of the whole discussion that this doctrine itself still requires further examination. At the same time, it is made fully clear that the writer accepts this metaphysical doctrine, with the reservation mentioned, and is passionately sincere in the faith in "personal immortality" which he brings into connection with it. To be strictly accurate, indeed, we ought to say that the faith to be defended goes beyond belief in "immortality." What is being maintained is the "divinity" of the soul, its survival of death as a consequence of this inherent divinity.¹

The argument is briefly as follows. A true philosopher may naturally look forward to death without dismay. For death is the separation of soul from body, and the philosopher's whole life has been spent in trying to liberate the soul from dependence on her body. In life, the body is always interfering with the soul's activity. Its appetites and passion interrupt our pursuit of wisdom and goodness, its infirmities are perpetually hindering our thinking. Even in our scientific work, we only attain exact and certain truth in proportion as we detach ourselves from reliance on sense-perception and learn to depend on pure thinking.

Death, then, only completes a liberation which the philosopher has been "rehearsing" all through life—if, that is, the soul continues to exist after death, as there are reasons for thinking. For.

I. There is a belief that the soul has a succession of many lives, and that when it is born into this world, it has come back from another. And there are two considerations to be urged on behalf of this belief. (a) The processes of nature in general are cyclical. The hot becomes cold, the cold hot, the waking go to sleep, the sleeping wake. It is reasonable to suppose that this applies to the case of dying and coming to life, so that the dead return to life, just as the living die. If this were not so, if the process of dying were not reversible, life would ultimately vanish from the universe. And (b) we may appeal to the doctrine that what we call "learning" is really "recollection," "being reminded" of something. This certainly seems to be the case, for in all our science we are perpetually being "put in mind of" precise ideal standards, mathematical or moral. We reason about exact quality, absolute justice and the like. Sense or experience never presents us with such perfect equality or justice, it only suggests them or "reminds us of them." We must therefore have become acquainted with them before we were confined to our bodies, and therefore must have existed before our birth. Now (a) and (b) together would prove what we want to prove, the soul's survival of death, though our "dread of the dark" makes us demand a more convincing argument.

II. We may consider the antithesis between the divine and eternal and the temporal and mutable, which runs through the

¹ Plato's belief in immortality ought never to have been disputed. It is re-affirmed in the most unqualified way in the seventh *Epistle* (335a-b), and his very latest work, the *Laws* (904c-905d), though the particular arguments of the *Phaedo* do not re-appear there. Aristotle, too, in his early days as a member of the Academy, had taught the doctrine in his *Eudemus* (*Fragmenta*, ed. Rose 37-48). This consideration is really decisive. The characteristic argument of the *Laws*, from the "self-moving" nature of the soul had already been used in the *Phaedrus* (245c). *Timaeus* 41a, where the final appeal is to the goodness of the Creator, formally applies not to men but to the stars.

universe. The body is certainly temporal and mutable. The soul is relatively immutable, like the fixed ideal standards or norms which she contemplates in her scientific thinking. Her thought is concerned with eternal objects and she herself has the likeness of that which she contemplates. If, then, some constituents of the body are nearly indestructible how much more should one expect the divine element in us, the soul, to resist destruction, as the traditions about re-birth assert that it does.

There are two grave "scientific" difficulties still to face. It may be argued (a) that the soul is an "epiphenomenon," the "tune" (*ἁρμονία*) given out by the body, and if so, its superior "divinity" will not protect it from vanishing when the instrument which makes the music is broken, (b) that though the soul actually makes its own body, and perhaps can make a long succession of bodies, it cannot do so without "expending energy"; a tune will come when it can no longer make a fresh body, and then it will itself disappear. We must not be driven into misology, antipathy to science, by this apparent clash between science and a faith to which we are attached.

The answer to (a) is that there are good souls and bad ones, and the good soul is "more in tune" than the bad one. But that which can be more or less "in tune" is clearly not itself a "tune." And if the soul were the "tune" resulting from the functioning of the body, its character at any moment would be a resultant of the condition of the body. How then could we have the experience, characteristic of the moral life, of the conflict between the soul with its aspirations and the body with its carnalities? The answer to (b) can only be given as part of a whole theory of the causes of "coming into being and passing out of being." Socrates had been led, early in life, to frame a tentative theory of the matter in consequence of his dissatisfaction with the chaotic state of physical speculation, and in particular with the failure of Anaxagoras to make any satisfactory use of his apparently teleological principle that "mind is the cause of all order and structure." He fell back on the method of "hypothesis."

What distinguishes this method from all others is that it begins by making an undemonstrated "postulate" (*ὑπόθεσις*). It then proceeds from this point to consider the truth or falsehood of the consequences which follow logically, from the initial postulate, the question of the truth of the postulate is, for the present, left unasked. Socrates' own fundamental unproved postulate has always been that usually, but loosely, called the "theory of Ideas." The postulate is that there really is a single determinate and immutable something (*εἶδος, ἰδέα*) answering to every significant "general term," and apprehended only by pure thought. The sensible things of which we predicate general terms temporarily "partake in" or "communicate with" the Idea or Form (*ἰδέα, εἶδος*). When we say that a thing becomes *e.g.* beautiful, what we mean is that the Form (*ἰδέα*) "beauty" begins to be "present to" that thing, the thing begins to "partake of" the Form. When we say that a thing ceases to be beautiful, we mean that this relation of "presence," "participation," "communication" (*ἡ παρουσία, μετέξις, κοινωνία*) is dissolved. This is the true account of the cause of "coming into and passing out of being," and if we accept it, we may proceed to our final argument for immortality.

III. There are Forms which are mutually incompatible, such as warmth and cold. Heat is never cool, and cold is never warm. But there are also certain sensible things of which it is an essential character to "partake of" a given Form. Such things will never admit an incompatible Form. Thus it is an essential character of snow to "partake of" cold. It will never, therefore, "partake of" the Form "heat." Similarly it is an essential character of a soul to be alive, to "partake of" the Form "life." It refuses to "partake of" the Form "death." At the approach of death, the soul must either retire or be annihilated (the metaphors are military). What we have said of its divinity forbids us to think that it is annihilated, we must therefore assume that it "retires" to some other region. The proof of immortality is thus hypothetical, it is shown to be involved as a consequence by the doctrine of Forms. This doctrine has been stated as a fundamental unproved postulate and it is admitted that it demands fuller consideration.

But our enquiry has at least satisfied us that the hope of immor-

taity is a reasonable one. (To distrust it would be to call the foundation of our whole philosophy into question.) The discourse ends with an imaginative cosmological myth depicting the future of the just and the unjust respectively.

In this statement of the theory of Forms (*lôai, eîdê*) we may note the following points: (1) The doctrine is a piece of "realist" metaphysics. It is assumed that a universally predicated "general term" denotes or stands for an individual reality, apprehensible by thought, though not by sense. (2) There are a plurality of such Forms, standing in various logical relations with one another; whether they constitute a system with a definite structure the *Phaedo* does not tell us. (3) They are at once the objects known in all genuine science and the formal causes of all the temporal processes of the sensible world. (4) The sensible things which have the same names as Forms are said to owe their character to their "participation" (*mêchêis*) of the Forms, or, equivalently, to the "presence" (*παρουσία*) or "communication" of the Forms to them. The precise character of this relation of "participation" is admitted to need further explanation. So far as the language of the *Phaedo* goes, a sensible thing would seem to be thought of as a temporary "complex" or meeting-place of universal characters and as nothing more.

Symposium, Phaedrus—It is by no means clear that these two dialogues are closely connected in point of date, but they may be considered together as both presenting the Forms in a special light, as objects of mystical contemplation and excitant of mystical emotion.

The argument of the *Symposium* cannot be reproduced here as a whole. The immediate object of the dialogue, which professes to record the discourses made in eulogy of Eros by a group of eminent speakers at a banquet in honour of the tragic poet Agathon, in the year 416-5, is to find the highest manifestation of the "Love" which controls the world in the mystic aspiration after union with the eternal and super-cosmic Beauty, to depict Socrates as the type of the aspirant who has reached the goal of "union," and to set in sharp opposition to him the figure of Alcibiades, who has sold his spiritual brightness for the pleasures and ambitions of the world. The centre of philosophical interest lies in the discourse of Socrates, which he professes to have learned a quarter of a century ago from the priestess Diotima of Mantinea.¹

The main argument may be summarized thus: Eros, *desirous* love, in all its forms, is a reaching out of the soul to a good to which it aspires but has it not yet in possession. The desirous soul is not yet in fruition of good. It is on the way to fruition, just as the "philosopher" is not yet in possession of wisdom but is reaching out after it.

The object which awakens this desirous love in all its forms is Beauty, and Beauty is eternal. In its crudest form, love for a beautiful person is really a passion to best by getting by that person and so to attain, by the perpetuation of one's stock, the *succedaneum* for immortality which is all the body can achieve. A more spiritual form of the same craving for eternity is the aspiration to win immortal fame by combining with a kindred soul to give birth to sound institutions and rules of life. Still more spiritual is the endeavour, in association with chosen minds, to reach philosophy and science with "noble discourses and thoughts."

But the goal still lies far ahead. When a man has followed the pilgrimage so far, he "suddenly descends" a Supreme Beauty which is the cause and source of all the beauties he has discerned so far. The true achievement of immortality is finally effected only by union with this. The philosopher's path thus culminates in a supreme "beatific vision." It is clear that the object of this vision, the "Beauty sole and eternal" of the dialogue, means what the *Republic* calls "the Good" or "Form of Good," which by its pres-

ent it is important to remember that Socrates professes to be repeating a lesson he had learned at about the age of 30. This explains at once the words of *Symposium* 202c, where Diotima expresses uncertainty about Socrates' achievement of the complete "vision." He has his life yet to live; what it will be is not revealed. That the words have been gravely misinterpreted as a claim on Plato's part to have transcended his Master's limitations is only one example of the nervousity with which he has been misunderstood.

ence actually causes the goodness of everything else to which the name of good can be given. The Forms are thus thought of as a hierarchy with a supreme Form at their head, though no attempt is made at a rational theory of the way in which the supreme Form unites the rest into the system.

The immediate subject of the *Phaedrus* is the principles of "rhetoric" or, as we should say, prose composition. The *Gorgias* had told us that "rhetoric" as commonly practised is not a matter of rational principles at all, but a mere empirical trick of adapting one's tone to the prejudices of an audience. The *Phaedrus* aims at showing how a really scientific "rhetoric" might be built on the double foundation of logical method and scientific study of human passions. Plato contrives, however, by making a real or supposed "erotic" composition of Lysias the starting-point of his criticisms, to unite with this topic a discussion of the psychology of "love," and this, as in the *Symposium*, leads him to speak of the Forms as the objects of transcendental emotion. The soul is immortal, because it has within itself a native source of spontaneous movement.² In its disembodied state it shared the life of the gods and could enjoy the direct contemplation of "unbodily" reality, that is, of the Forms. It has suffered an *anænatal* fall into an embodied condition in which it is blind to everything which does not come in at the avenues of sense.

Now our senses only suggest few and faint images of such Forms as Justice and Temperance, but they can suggest Beauty in a much more impressive and startling way. To "fall in love" is to come under the influence of such sudden and arresting suggestions of Beauty, the "unreason" and "madness" of the lover mean that he is being awakened to realities which other men ignore. The "wings" of his soul are beginning to grow again, and his experience, rightly used, will be the first step in the soul's return to its high estate. This section of the *Phaedrus* is the *locus classicus* in Plato for the Forms as objects of mystical contemplation.

Republic—The philosophy pre-supposed in all these dialogues receives its fullest exposition in the *Republic*. Here the immediate problem is strictly ethical. What is Justice (*tô dikaion, dikaiosynê*)? Can it be shown that Justice is always a boon, injustice a curse, to its possessor, apart from all consideration of consequences in this life or another? That is, is there a rational principle at the root of moral distinctions, and does the principle carry with itself its own intrinsic and indefeasible authority?

Plato's answer is that there is such a principle, each of us, in virtue of his special endowments and aptitudes, has a specific "work" or "vocation", there is some special contribution which he, and no other, can make most effectively to the life of a rational society. Morality, "Justice," is to discharge that vocation to the height and with a single mind (*tô αὐτοῦ πράττειν καὶ μὴ πολυπραγμονεῖν*). To live thus is to be in spiritual health, to live otherwise is to be spiritually diseased. The obligation is thus intrinsic and absolute. This position has to be made good against the incoherencies of a morality of uncriticized traditional maxims, as well as against the "immoralism" of advanced thought (represented by Thrasymachus in Bk I, expounded more intelligently by Glaucon in Bk II.)

This leads us to consider what would be the general type of life in a society where the principle of Justice had power as well as manifest authority, and how it might acquire that power. Hence the need for a sketch (II, III) of the institutions of the reformed society, and particularly of its moral and religious education. We have next to satisfy ourselves that the principles which regulate the public life of the morally healthy society are also recognizably the principles of the great virtues of private life. For this purpose, we need a psychology of voluntary action which is provided (Bk IV) by the doctrine of the "tripartite soul." This is not, indeed, a scientific psychology, but proves adequate to describe the moral life of the ordinary good citizen of such a society as we have conceived. The foundation of all this moral excellence

¹This is the argument for immortality to which Plato trusts in the *Laws*. It is not specially mentioned in the *Phaedo*, but this can hardly mean that Plato had not yet discovered it, since it is, in fact, taken from Alcmaeon of Crotona, a medical man of the beginning of the fifth century.

is thus laid in absolute loyalty to a sound moral tradition enforced by education. To ensure that the tradition shall be thoroughly sound, we must stipulate that the authorities who create it do not themselves depend on tradition for their convictions about good and evil, they must not "opine," but know, by personal insight. The statesmen at the head of the community must be "philosophers" as well as kings (Bk VI).

But the vision of "the Good" will only dawn on them if they have been prepared for it by an intellectual discipline in hard thinking which leads them through the curriculum of the exact sciences to the critical study of the metaphysical principles involved in science (Bk VII). The central books of the *Republic* thus present us with an outline of metaphysics and a philosophy of the sciences. We now turn back to consider the various stages of degeneration through which national and personal character pass when the true moral ideal is allowed to fall more and more completely out of view. As we pass them in review, we are increasingly confirmed in our conviction that, in respect of happiness, the life of regard for right is immeasurably superior to that of satiating one's cupidities or gratifying one's personal ambitions (VIII-IX), and this conclusion is finally clinched (X) by re-affirmation of the immortality of the soul. Since the soul is immortal, the issue which hangs upon our choice to live well or ill is one of infinite moment. (X)

The ethical scheme of the *Republic*, like that of the *Gorgias* and *Phaedo*, is dominated by the conception of the "three lives," ascribed by credible tradition to Pythagoras. The "lives" are those of the philosopher, the "man of action" (*φιλόνομος*), the votary of enjoyment (*φιλόθεος, φιλοκόσμος, φιλοχρήματος*). The end of the first is wisdom, of the second, distinction, of the third, the gratifications of "appetite." Distinction is a worthier end in life than mere satisfaction of appetite, the supremely worthy end is wisdom. In a well-lived life, then, the attainment of wisdom will be the paramount end, and ambition and appetite will only be allowed such gratification as is compatible with loyalty to the pursuit of that paramount end. The psychological foundation of this doctrine is the theory of the "tripartite" soul, expounded fully in *Rep. IV*. Analysis of familiar experience reveals three "elements" (*μέλη, εἶδη*) or "active principles" within us, (1) considered rational judgment of good (*τὸ λογιστικόν*), (2) a multitude of clamant appetites for particular gratifications, which may be in violent conflict with our own considered judgment of good (*τὸ ἐπιθυμητικόν*), (3) a factor of "spirit," higher "ideal emotion," which manifests itself as "resentment" against both the infringement of our just rights by others and the rebellion of our own appetites against our judgment (*τὸ θυμοειδές*).

The same distinctions reappear in the structure of society. A society naturally falls into three divisions, the statesmen, who direct the public life, the general civilian population, who carry on the business of providing for material needs, and the executive force (army and police), whose function is, in a rightly ordered society, to give effect to the counsels of the statesmen by repressing attacks from without and rebellion from within.

These three "orders" are thus respectively, the judgment, the "appetitive" and "spirited" elements in the national soul. On this basis, we can proceed to work out an ethical and political theory. In ethics we can define the great leading types of "goodness," the quadrilateral, later known as the four "cardinal" virtues. Wisdom is the "excellence" of the "thinking part," clear and assured knowledge of the good; courage, the fighting man's virtue, is the "excellence" of the "spirited" part, unswerving loyalty, unshaken by pain, by danger, by the seductions of pleasure, to the rule of life laid down by judgment, temperance, the special excellence of the "appetitive" part, is the contented acquiescence of the non-rational elements in the soul in the plan of life prescribed by judgment, justice is just the state in which each of the elements is vigorously executing its own function and confining itself within the limits of that function. In the rightly ordered society, the national wisdom has the statesmen as its organ, the national courage the executive force, the national temperance is shown in the loyal contentment of each class in the community with its prescribed place and its duties.

Such a society is a true aristocracy, or rule of the best, "timocracy" the military state, in the better sense of that phrase, arises when the mere "man of action," only competent to fill the part of a good soldier, takes the place which rightly belongs to the thinker as directing statesman, "oligarchy" (*εἰς*), the dominance of "merchant princes," "plutocracy," is a further deviation from the ideal, which arises when political power is bestowed on property as such. A still worse system is democracy, in which no attempt is made to connect political power with any special qualifications. Worst of all is tyranny, exercise of irresponsible power by the positively disqualified, the man of "criminal" will. The psychological scheme on which this construction is based is not given by Plato as a piece of strict science. We are carefully warned that exact truth is not to be reached by such an analysis of *prima facie* facts of social life (435 d), and reminded later on that this apparent triplicity of the soul may prove to be only a temporary consequence of its conjunction with the body (611 b).¹ The "tripartite" psychology, it is meant, enables us to give an account of the moral life, as it actually appears in a good citizen, which will fairly describe the facts. It is good popular psychology, useful for the moralist, but is no more.

Hence it is improbable that the analysis originated with Plato himself. More probably it was, as the Stoic Posidonius asserted, a piece of earlier Pythagorean doctrine, as is also suggested by the constant recurrence, throughout the section of the *Republic* in which the analysis is offered, of analogies from the specially Pythagorean science of Harmonics, and by the fact that the same doctrine is taught by the Pythagorean speaker in the *Timaeus*. Plato has, however, worked the theory into his ethics so completely that through him it has actually become a part of the psychology of Thomism, where it has to be squared, not quite satisfactorily, with the radically divergent psychological scheme of Aristotle.

In point of fact, the tripartite schema proves inadequate in the *Republic* itself when we advance in Bk VI to the consideration of the moral life of the "philosopher-king," whose "virtue" is founded on a personal knowledge of good. A higher level of moral goodness is demanded of him than of other citizens even of the ideal Utopia, his courage, for example, is declared to be no mere loyalty to right opinions inculcated by early education, but a high serenity arising from the knowledge of the relative insignificance of a brief individual life in the great universe which has open to his contemplation. This has an important bearing on the teaching of the *Republic* about the unity of virtue.

In the ideal State itself, virtue does not appear as a complete unity. The leading types of moral excellence receive their several definitions. It is recognized that a special demand may be made on a particular section of the society in respect of a particular virtue of which it is, so to say, the public organ, as the fighting force is of the valour of the whole society. This is because, even in the ideal state, the moral convictions of citizens, other than the men of superlative intelligence and character who become "kings," are not supposed to arise from personal insight. They rest on opinions implanted by education, and are thus taken on trust. The good civilian or soldier, after all, is not living by a knowledge which is his own. But the rulers, by whose knowledge the rest of the community lives, must not, of course, themselves take their convictions on trust. They must know with a personal knowledge. The foundation of their virtue must be *insight* into a system of absolute values embodied in the very structure of the universe. In virtue of this deeper foundation the virtues in them are, so to say, transubstantiated and can no longer be distinguished from one another. They will fuse in knowledge of the good, as, in the Christian saints, they are fused in knowledge and love of God. It is in this form that the Socratic doctrine, "all virtue is one thing, knowledge" reappears in the *Republic* as the foundation of a society in which mankind has at last "escaped from its wretchedness," because knowledge rules.

In the *Republic*, as in the *Phaedo*, the Forms (*ἰδέαι, εἶδη*) ap-

¹Timaeus is expressly made to teach that the *θυμοειδές* and *ἐπιθυμητικόν* are a "mortal element" (*θνητὸν εἶδος*) added to the immortal soul to fit it for its habitation in the body (*Tim. 69c*).

pear in the double character of objects of all genuine science and formal causes of the world of events and processes. It is expressly denied that there can be knowledge, in the proper sense of the word, of the temporal and mutable. In the scheme laid down for the intellectual training of the philosophic rulers, ten years, from the age of 20 to that of 30, are assigned for systematic study of the exact sciences in the order: arithmetic, plane geometry, solid geometry, astronomy and harmonics. Special stress is laid on the points that the object of these studies is not practical applications but the familiarizing of the mind with relations between terms which can only be apprehended by thought, and that diagrams and models are to be treated merely as incidental aids to imagination. Five years are then further to be given to the still severer study which Plato calls "dialectic," a study which avails itself of no sensible aids to imagination. It proceeds "by means of Forms, through Forms, to Forms" (511 b). It is, in fact, what we should call a critical metaphysics of the sciences. It examines the *ὑποθέσεις* or unproved postulates, of the various sciences, and its object is to "destroy" their character as unproved ultimate postulates (*τὰς ὑποθέσεις ἀναρροῖα* 533 c) by discovering some still more ultimate really self-evident principle (an *ἀνυπόθετον*, 511 b) from which they follow as consequences.

There can be no doubt that this most ultimate principle which is more than a "postulate" means the Good or Form of Good (*ἡεὶς τὰγαθόν*) which is said to be the source at once of the reality and the knowability of all that is real and knowable, though it is itself neither knowledge nor being, but transcendent of both (509 b). On the methodological side the *Republic* thus completes the teaching of the *Phaedo* by providing the answer to the question then left open, when a "postulate" (*ὑπόθεσις*) may be regarded as finally established. It may be so regarded when it is seen to follow itself from the Good, which is the principle at once of existence and of value.

Socrates is made to confess (506 d-e) that he can give no positive account of this supreme metaphysical principle, he can only indicate its nature by an analogy. It is to the whole system of Forms what the sun is to the system of visible things, the source at once of their existence and of the light by which they are apprehended. The Good is thus thought of, to use scholastic terminology, as a transcendent reality which can be apprehended but never fully comprehended. The comparison with the sun and the free employment of the metaphor of "vision" indicate that the thought of the *Republic* is here the same as that of the *Symposium*; the Good is no other than the supreme Beauty which was there said to dawn suddenly upon the pilgrim of "Love" as he draws near to the goal of the journey. R. L. Nettleship rightly says that it holds the place taken in later philosophies by God, when God is thought of as the "Light of the world." But it would be deforming Plato's thought to call the Good of the *Republic* "God." The *Republic* is permeated by religious faith, but Theism as a principle of metaphysical explanation only makes its appearance in Plato's latest dialogues, and there as the solution of a problem which can hardly be said to have been adequately faced in the dialogues so far considered.

How the Good gives systematic structure to the plurality of Forms, the *Republic* does not tell us.

Development of the Doctrine of Forms.—So far we have been presented with a body of thought which has remained recognizably the same without serious modification throughout its various expositions. When we come to the two works which there is reason to regard as directly prelude to the dialogues of Plato's old age, the *Parmenides* and *Theaetetus*, we are struck by a remarkable difference of tone. With Plato, as with Kant, the "middle years" of life were clearly a period of fruitful critical reconstruction. There is an obvious motive for each reconstruction suggested by the *Phaedo* and *Republic* themselves.

The theory there expounded does not allow enough reality to the sensible world. It is quite false to say that even the *Phaedo* teaches an "absolute dualism" of two disconnected worlds, a realm of genuine being which never "appears" and a realm of sensible appearances which are merely unreal. What is true is that both *Phaedo* and *Republic* leave us with an unsolved problem. They

tell us that a sensible thing is a complex or meeting-place of a plurality of Forms. What else, or what more, it is they do not tell us. And yet it is clear that a "thing" is not simply a bundle of "universal predicates."

Or, to put the point rather differently, according to the *Phaedo* a thing becomes for a while beautifully because Beauty "becomes present to it." But why does Beauty become present to this particular thing at just this particular moment? Clearly the relation between a "thing" and a Form which has been called "participation" needs further elucidation. Again the simple epistemological formula that knowledge is confined to Forms and their relations, while we can only have shifting "opinions" about temporal facts does less than justice to our scientific knowledge of the natural world, "truths of fact" have not yet come by their rights. Finally, if the Forms constitute a rationally ordered system, there must be definite principles of inter-relation between Forms themselves as well as between Forms and sensible things and these principles demand investigation (If the Good is what the *Republic* says it is, not only will things "participate" in Forms, Forms also will "participate" in it.) Here are internal motives for active re-examination of the whole system.

It is clear that there was also an external motive. *Parmenides*, *Theaetetus*, *Sophistes*, all reveal a special interest in the Eleatic philosophy, and the first and third show an anxiety on Plato's part to maintain that, in spite of important divergences, he, and not the professed Eleatics, is the true spiritual heir of the great Parmenides. This is easily explained when we remember that Plato was personally a friend of the chief representative of Eleaticism among the Socratic circle, Euclides of Megara, while Polyxenus of Megara, an associate of Euclides, was a hostile critic of the doctrine of "participation." The doctrine of Euclides, like that of Parmenides was that "sensible appearances" are illusions with no reality at all. Against criticism from this quarter, it would be necessary for Plato to show that the *Phaedo* itself does not allow too much reality to the sensible; the attempt to prove this point would inevitably show that it had conceded too little. Continued reflection on the same problem of the worth of propositions about sensible fact leads straight to the discussion of the meaning of the *copula*, and the significance of denial, which is the subject of the *Sophistes*.

Parmenides.—Formally the dialogue conducts to an *impasse*. In its first half the youthful Socrates expounds the doctrine of the "participation" of things in Forms to the Eleatic philosophers, Parmenides and Zeno, as the solution of the problem of the One and the Many. Parmenides raises what appear to be insoluble objections to the conception of "participation," though he admits that "dialectic" would be impossible if the existence of Forms were denied, he hints that the helplessness of Socrates under his criticism arises from insufficient training in logic.

In the second and longer half, Parmenides gives an example of the logical training he recommends. He takes for examination his own thesis, "the One is," and constructs an elaborate set of antinomies after the fashion of Zeno, apparently proving that whether this thesis be affirmed or denied, in either case we are compelled either to affirm simultaneously or to deny simultaneously a series of contradictory predicates, alike of the "One" and of the "Many." The conclusion is patently ironical, and we are left to divine the author's purpose, if we can.

The objections to "participation," which is formulated precisely as in the *Phaedo*, are directed not against the existence of Forms, but against the possibility that sensible things should "participate" in them. From the point of view of this criticism Socrates' error is that he attributes some sort of secondary reality to the sensible. The main arguments are two: (1) the doctrine does not really reconcile unity with plurality, since it leads to a *regressus in indefinitum*. It says that the many things which have a common predicate "participate of" or "imitate" a single Form. But the Form itself also admits of the common predicate, and there must therefore be a second Form, "participated" or "imitated" alike by the sensible things and the first Form, and so on endlessly. We could not escape by the suggestion that the Form exists only "in our

¹Alexander Aphrodis. on Aristot. *Met.* 990 b. 17.

minds," since that would mean that a Form is a thought, and it would follow that "things" are made of thoughts. But if so, either everything thinks, or there are thoughts which do not think, and both alternatives are absurd, (2) it is a still graver difficulty that if there are two realms, a realm of Forms and a realm of sensible things, the relations between Forms must belong to the realm of Forms, those between sensible things to the realm of things. We ourselves belong to the second, and therefore all our knowledge belongs to it too, we know nothing of the true realities, the Forms if anyone knows them, it is God, but God's knowledge, being knowledge of realities, will not extend to *our* world, the sensible. The purpose of the objections is thus to suggest that the "manifest of sense" has not even a derivative reality, it is mere illusion.

This is precisely the position of the Eleatics and their Megarian contrivators. The inference is that Plato is reproducing Megarian criticisms of the doctrine ascribed by himself to Socrates, an inference confirmed by the notice preserved by Alexander of Aphrodisias (on *Met.* 990 b 15) of the "third man" argument of the Megarian Polyxenus against "participation." Plato does not indicate his own opinion of the cogency of the reasoning, which is, in fact, fallacious, as was properly pointed out by Proclus.¹

The purpose of the antinomies which follow has been very differently understood. In the present writer's opinion, they are deliberate parody, the object being to show that the methods of the Megarian logicians are even more damaging to their own fundamental metaphysical tenet than they are to the doctrine of "participation." Megarian logic is a double-edged weapon, and Plato, if he chooses, can apply it even more dexterously than its inventors.

Theaetetus.—Except for a magnificent interlude in praise of the contemplative life, the dialogue is a straightforward discussion of the question how knowledge should be defined. It naturally ends negatively. None of the proposed definitions will stand examination (the reason is that we are really trying to define truth and truth is an ultimate). But the incidental results of the discussion are of the first importance. We learn (a) that knowledge cannot be identified with sensation nor with any formless "simple apprehension", (b) that pure relativism is as impossible in epistemology as in metaphysics. We have the beginning of a doctrine of the "categories" which is further developed in the *Sophistes*.

The increasing value which Plato is coming to put upon "natural knowledge" is marked by the use of the word *δόξα*, which in earlier dialogues had commonly meant mere uncertain "opinion" as contrasted with knowledge, in the new sense of "judgment" which it retains in Plato's subsequent work. The most striking negative feature of the *Theaetetus* is that it discusses knowledge at length without making any reference to the Forms and the mythology of "recollection." It remains to this day the best of introductions to the "problem of knowledge."

The main argument may be very briefly summarized thus. I. It seems plausible at first to say that knowledge (*ἐπιστήμη*) is sensation (*αἰσθησις*). This sounds very much like the proposition of Protagoras, "what seems to me is so to me, what seems to you is so to you." We might base such a thorough-going doctrine of the relativity of all knowledge on a still more ultimate metaphysical theory, if we said—it is implied that Protagoras himself said nothing of the kind—that, within us and without us, the only reality is motion. "Organ" and "environment" are both motions, when these motions impinge on one another, they give rise to the twin-product, felt sensation—sensible quality.

Both the sensation and the quality "sensed" will therefore be affected by any difference in the pair of slower "motions" which cause them (the "organ" and its "environment"), and each perceptive, therefore, is confined to his strictly private world, which exists only "for" him. There is no "common" perceived world, and therefore no standard of truth or reality other than the individual perceptive. A teacher does not aim, any more than a physician, at convincing his pupil of the "falsity" of his judgments, but at giving him "useful" or healthy convictions in place of harmful or diseased convictions.

¹For a detailed discussion of it, see A. E. Taylor, *Farmenides, Zeno and Socrates* (Transactions of Aristotelian Society, N. S. xvi. 234 ff.)

The full discussion of such a theory would demand a thorough study both of the Heraclitean philosophy, which says that there is nothing but motion, and the Eleatic philosophy which says that motion is an illusion. But for our immediate purpose, a more summary argument is sufficient. It is certain that even the relativists, who hold that each man is the one infallible "measure" of his present perceptions, do not hold that he is the only and inerrant measure of his future sensations. A physician can often judge better than his patient whether the patient is going to have, e.g., the sensations of an ague. A man's own opinion whether a certain course will be expedient or good for him is often far from being the soundest. We must distinguish carefully between what the mind perceives "through bodily organs"—the data of sense—and the things she apprehends "by herself" (*αὐτῇ δὲ αὐτῆς*) without "organs." These latter include number, sameness, difference, likeness, unlikeness, being, good, bad, right, wrong, i.e., the great universal "categories" of fact and value. These are apprehended not by sense, but by thinking, and as they are the formal element in all knowledge, knowledge must be found not in our sensations, but in "the judgment (*συλλογισμός*) of the mind upon" them.

II. Is knowledge, then, "true judgment?" The statement implies that we know what we mean by "false" judgment, error. But is this the case? Error must not be confused with mere false recognition, misinterpretation of present sensation, since there are purely intellectual errors, and we find ourselves unable to explain the nature of this kind of error. And, in fact, it is clear that persuasive rhetoric may produce in the hearer judgments which are true, but have no claim to be called knowledge. III. Finally, is knowledge "true judgment accompanied by discourse (*μετὰ λόγου*)", true judgment for which we can give grounds? This would distinguish knowledge from "simple apprehension" and would harmonize with the theory of those who hold that knowledge is always of complexes, never of their simple constituents. But this doctrine has difficulties of its own, and, in any case, if we say that knowledge is true judgment + "discourse," the "discourse" meant must be a statement of the logical *differentia* of the object of which I have knowledge. The proposed definition therefore amounts to saying that knowledge is true judgment about an object + knowledge of the *differentia* of that object, and so is circular.

LATER DIALOGUES

Sophistes and Politicus.—Formally these two important dialogues are closely connected. They are made to appear as a sequel to the *Theaetetus*, and a further connection is afforded between them by the fact that both are ostensibly concerned with a problem of definition, which is treated by the characteristic Platonic method of repeatedly subdividing a *genus* until we obtain the *definiendum* as a sub-species. The real purpose of the *Sophistes* is logical or metaphysical; it aims at explaining the true nature of negative predication and so disposing of the Eleatic thesis that the temporal and sensible realm, containing, as it does, a negative moment, must be mere unreal illusion. The object of the *Politicus* is to consider the respective merits of two contrasted forms of government, "personal rule" and "constitutionalism," and to recommend the second, particularly in the form of "limited monarchy," as most suitable to the actual condition of mankind. The *Sophistes* lays the foundations of all subsequent logic, the *Politicus* those of all "constitutionalism."

A more temporary purpose in both dialogues is to illustrate the value of careful classification as a basis for scientific definition. In both dialogues Socrates is almost silent; his place as chief speaker is taken by an unnamed and very unorthodox Eleatic, who seems to be a purely fictitious character. Plato is, in fact, claiming that he, and not the formal logicians of Megara, is the continuator of Parmenides, much as Aristotle in his polemic against Xenocrates claims to be the true successor of Plato.

In the *Sophistes* the main discussion is led up to through a definition of the "sophist" as an "illusionist," a person who, by abuse of logic, produces the illusion, or false appearance, that nature and human life are alike riddled by insoluble contradictions. (This shows that the persons aimed at under the name "sophist" are the

Megarian controversialists who make an illegitimate use of the dialectic of Zeno and Socrates.) Now the "sophist" himself would retort that this definition is senseless, for there can be no such thing as a false statement or a false impression. For the false means "what is not," and "what is not" is nothing at all, and can neither be uttered nor thought. To refute him we need to correct the fundamental thesis of so venerable a thinker as Parmenides.

We must either admit that there can be no false statements, or we must be prepared to maintain that "what is not, in some sense also is," and "what is, in some sense is not" (*i.e.*, we must explain what is the meaning of a significant negative proposition). In our theory of "being" we have to meet at once Parmenides and two different types of pluralist opponents of Parmenides, (a) the corporealists who say that the real, "what is," is just visible and tangible body, and (b) certain "friends of Forms" who maintain that the real is a multitude of incorporeal Forms, denying that sense-perception gives us any apprehension of it. The corporealist is sufficiently refuted by the consideration that he himself cannot deny the reality of "force" (*dynamis*) and that force is not a body. The incorporealist "friends of Forms" cannot be met in this way. They regard force, or activity itself as belonging to the unreal realm of "becoming." We meet them by urging that knowing is itself an activity and that we cannot deny intelligence and knowledge to the supreme reality. This means that it has a "soul" and is alive. But if life is real, movement and repose from movement must be real too.¹

This leaves us free to attack the Parmenidean Monism itself. That is refuted by drawing the distinction between absolute and relative "non-being." A significant denial, *A is not B*, does not mean that *A* is nothing, but that *A* is other than *B*. Every one of the great categorical features of reality is other than every other, and the true business of "dialectic" is to study the various possible combinations of these universal "categories." The dialogue mentions five of them, being, identity, difference, motion and rest. It is not said that this is a complete list of "categories," though it was treated as such by the Neo-Platonists.

The important result is thus that we have learned to think of Forms themselves as an inter-related system, with relations of compatibility and incompatibility among themselves. Negation is a moment in the system of intelligible reality, and therefore its presence in the sensible realm does not stamp that realm as illusion. This is the ontological position which interests Plato; the recognition of the function of the logical *copula* is a consequence.

The *Politicus* has as its main result the conclusion that government by the personal direction of a benevolent "dictator" is not suitable to the conditions of human life, where the direction is necessarily that of a fallible man, not of a god. In an actual human society, the surrogate for personal direction by a god is the impersonal supremacy of inviolable law. Where there is such a recognized sovereign law, monarchy is the most satisfactory type of constitution, democracy the least satisfactory, but where there is no "fundamental law," this situation is inverted. A "sovereign" democracy is preferable to an irresponsible autocrat. The dialogue is rich in thoughts which have passed into the substance of Aristotle's ethics and politics. Aristotle took directly from it the conception of "politics" as the "architectonic" practical science to which all others are subordinate, the formula of the "right mean" comes from it together with the *Philebus*.

Philebus.—The subject of the dialogue is a strictly ethical one, and this, no doubt, explains why it is the only dialogue after

the *Theaetetus* in which Socrates is the principal speaker. The issue propounded is the question whether the "good" is pleasurable feeling or whether it is thought, the exercise of intelligence.

Comparison with the notices of Aristotle in the *Nicomachean Ethics* shows that this was the subject of a sharp division in the Academy, the Hedonist party being led by the mathematician and astronomer Eudoxus, the anti-Hedonists by Speusippus. Under the guidance of Socrates the question is narrowed down to a consideration of the good for *man* in particular, and a mediating conclusion is reached. The best life for *man* contains both elements, but intelligence is the "predominant partner."

All forms of knowledge find a place in it, but only those pleasures which are compatible with wisdom and virtue, *i.e.*, those which are "unmixed," not preceded by a sense of want or craving, and those of the "mixed" pleasures, the satisfactions of appetite, which are innocent and moderate. The *Philebus* contains Plato's ripest moral psychology; it is the immediate source of the famous "doctrine of the Mean."

Philosophically the most important feature of the dialogue is a classification adopted with a view to determining the formal character of the two claimants to recognition as the good. All components of the actual belong to one of four classes, (1) the infinite or unbounded (*ἄπειρος*), (2) the limit (*πέρας*), (3) the mixture or combination of (1) and (2), (4) the cause of the mixture ([1] and [2] are just the two fundamental "opposites" of Pythagoreanism.) All the good things of life belong to (3), that is, they are produced by the introduction of definite "limit" or "ratio" into an indeterminate "continuum." (This is precisely the doctrine of the "Mean.") The establishment of such a "ratio" is a *γένησις ἐκ ὁλκίας*, a process resulting in a stable "being," and it is indicated that the cause or agent in such a process is always intelligence, human or divine.

There has been much discussion of the question in which of these "classes" the Forms should be placed. The only tenable alternatives would be to put them into the class of "limit" or into that of the "mixture" (a view suggested both by the teaching of the *Sophistes* and by Aristotle's express statement that Plato distinguished two constituents within the Form and advocated ably by Dr H. Jackson). The truth seems to be that the particular classification in the *Philebus* is devised for a special purpose, and that it is not intended to apply to anything but the things and processes of the sensible realm. In that case, though there is a close correspondence between what the *Philebus* teaches about "stable being" in the sensible realm and what, as we know from Aristotle, Plato taught about the Forms, it will be a mistake to look for any actual exposition of the metaphysics of the Forms in the *Philebus*.

Timaeus.—The *Timaeus* is an exposition of cosmology, physics and biology put into the mouth of the astronomer Timaeus of Locri. Though Plato avoids expressly describing the speaker as a Pythagorean, his doctrine is revealed by attentive analysis as an attempt to combine the mathematics and astronomy of the Pythagoreans with the biology of Empedocles, the real founder of Sicilian medicine. The discussion is introduced by the famous narrative of the gallantry of the prehistoric Athenians who defeated the kings of the imaginary Atlantis in their ambitious attempt to become masters of the world. The story was to have been told more in detail in the unfinished *Critias*.

Timaeus opens his discussion by drawing a sharp distinction between eternal being and temporal becoming, and insisting on the point that it is only of the former that we can have exact and final knowledge. All accounts of the temporal can be only tentative and liable to repeated revision. Cosmology, then, at best, is not exact science. The visible world, being mutable and temporal, is a copy of a model which is eternal, and the copy is the work of God. The reason why there is a copy at all is the unceasingly active and generous goodness of God. (In the sequel Timaeus speaks of the Forms which God had before Him as His model in much the same language as the *Phaedo*, except that he uses the Pythagorean word "imitation," not "participation," to describe the relation of sensible things to Forms.)

The world, then, had a beginning (The Academic tradition from the first was that this is not to be understood literally, Aristotle

¹It is still a much agitated question who are the "logical atomists" described in the *Sophistes* as the "friends of Forms." The view that they are adherents of the philosophy of the *Phaedo* and *Republic* is deservedly dead. They are still often supposed to be Megarians, but this seems inconsistent with the way in which they are carefully distinguished from the followers of Parmenides as belonging to "the other side" at 245 *e* Proclus (*in Parm.* 562 St.) says positively, as though it were the only view known to him, that they are Italian Pythagoreans, and this is probably correct, since the Eleatic of the dialogue refers to them as persons with whom he is "familiar." It is important to remark that the identification of "being" with "force" is given merely as a consequence which would follow from, and contradict, the corporealist "hypothesis." The implication of the passage is rather that the identification is false than that it is true.

insists on taking it literally.) God first formed its soul out of three constituents, Identity, Difference, Being. Its body was made later from the four Empedoclean "elements." The world-soul was placed in the circles of the sidereal Equator and Ecliptic, the latter being split into seven lesser circles, those of the planets, and the two were animated with movements in opposite senses. Subsequently were formed the various subordinate gods and the souls of human beings, that is the "immortal" and rational element in the human soul, which come straight from the hands of God Himself. The formation of the human body and of the two lower "mortal" components of the human soul was effected through the intermediacy of the "created gods" ($\gamma\epsilon\tau\epsilon$, the stars). The most important question of detail arising from this part of the dialogue is that debated between Boeckh and Grote. Does Timaeus ascribe a motion to the earth? The restoration of the correct text at 40c¹, proves definitely that he does, but it is not a diurnal revolution, as Grote supposed, it must be rectilinear displacement of unknown period. The contact is made between Pythagorean geometry and the Empedoclean biology which will be needed for the physiology and medicine of the dialogue by a mathematical construction of the "elements."

Starting with two primitive triangles, the isosceles right-angled, and the right-angled scalene in which the hypotenuse is double the shortest side, Timaeus constructs four of the regular solids, cube, tetrahedron, octahedron, icosahedron, and these are assumed to be the shapes of the corpuses of earth, fire, air, water. These four in their turn are the immediate constituents of all organic and inorganic compounds.

The important features of the dialogue are not the particular tentative scientific hypotheses but its leading methodological principles. We should note the introduction of God as the intelligent efficient cause of all order and structure in the world of "becoming," which precludes to the natural theology of the *Laws*, and the emphatic recognition of the essentially tentative, and therefore progressive, character of natural science. It is also noticeable that though Plato's scientific ideal is a mathematical corporeal physics, his influence in creating this ideal has been much more important than that of the ancient Atomists—he constructs his physical world without "matter" as a metaphysical "substrate." The place of matter is taken in his analysis, as Aristotle complained, by $\chi\omega\rho\alpha$, space, as in the *Principia* of Descartes, a point of view to which physical speculation seems to be returning. He analyses the "passage of Nature" into three factors $\delta\upsilon\upsilon$ ("being": a Form), $\chi\omega\rho\alpha$ (space), $\gamma\eta\nu\epsilon\sigma\iota\varsigma$ (happening), much as Whitehead analyses it into "objects," "events" and the "ingredience of object into event."

It is a fundamental point that the presence of $\chi\omega\rho\alpha$ as a factor makes it necessary to recognise over and above "God" or "mind" a subordinate element of $\alpha\nu\acute{\alpha}\gamma\kappa\eta$, "necessity" in events. Since necessity is also called the "extrant" cause, $\pi\lambda\alpha\nu\omicron\mu\epsilon\nu\eta\ \alpha\iota\tau\iota\alpha$ (with an allusion to the name of the "planets" or "tramp-stars") the word clearly does not mean "conformity to law." It is rather a name for the fact that there is always in the actual an irreducible remainder of "brute" datum, "conjunctions" in Hume's phrase, which we cannot rationalize completely into intelligible "connections." Thus $\alpha\nu\acute{\alpha}\gamma\kappa\eta$ is not a rebel or evil principle in the constitution of things, its function is everywhere to be instrumental to the intelligent and beneficent purpose of "mind" or God. There are many facts which we have to be content to accept.

The words used of the earth $\delta\iota\alpha\lambda\omicron\mu\epsilon\nu\eta\ \tau\eta\nu\ \pi\epsilon\rho\iota\ \tau\eta\nu\ \delta\iota\alpha\ \pi\alpha\nu\tau\acute{\omega}\varsigma\ \pi\epsilon\delta\upsilon\nu$ *τεταμένην* admit of only one rendering "going up and down on the path about the axis of the universe." Timaeus thinks of the earth as placed about the $\nu\alpha\varsigma$ of the whole universe and being displaced to North and South by a sliding movement along this axis. Aristotle was then exactly right in saying that Timaeus teaches that the earth "is at the centre" and moves there (*de Caelo* 293 b30) and distinguishing this view carefully from that which he ascribes to the Pythagoreans, "that the earth revolves as a planet about the centre." It is this second view which is implied in the language of *Laws* 832a and *Epinomis* 98b and expressly attributed to Plato "in his later years" by Theophrastus ap. Plutarch *Quaest. Plat.* 1006c. There is no reason to suppose that Plato ever himself held the curious view he has ascribed to his fifth century Pythagorean. He has his own reasons for insisting as strongly as he does on the provisional character of all the science of the dialogue.

simply as facts without seeing their "reason-why." We do not know and may never know, why it is "best" that they should be as they are—e.g., why "it is best" that we should live on a moving earth—but we may be sure that, since it is the fact, it is in some way best that it should be so. This seems to be what is meant by the statement that God or "mind" ($\nu\omicron\upsilon\varsigma$) persuades $\alpha\nu\acute{\alpha}\gamma\kappa\eta$. It is the expression of a rational faith in Providence and the supremacy of the moral order. The details of the cosmology, physiology and psycho-physics of the dialogue are of great importance for the history of science, but metaphysically of secondary interest.

Laws and Epinomis.—The *Laws*, Plato's longest, is also his most intensely practical work, and contains his ripest utterances on ethics, education and jurisprudence, as well as his one entirely non-mythical exposition of theology. The immediate object is to meet a practical need by providing a model of constitution-making and legislation for members of the Academy who may be called on to assist as advisers in the actual founding or re-founding of cities.

Plato's attempt to do work of this kind himself, at Syracuse, had borne no immediate fruit, but had given the Academy a recognized standing as a school of scientific politics and jurisprudence. The work of constitution-making and legislation was going on in many quarters at the end of his life, and his experience might be made fruitful in sage counsels to younger men. The practical character of the subject explains some novelties in the outward form of the work. As the dialogue is assumed to be dealing with the actual present, Socrates has disappeared and his place is taken by an unnamed Athenian who is, to all intents, Plato himself.

The scene is laid in Crete, the imagined situation is that the Cretans are about to found a settlement on the site of a long deserted city. The chief Commissioner for the project is walking out to inspect the proposed site with a Spartan friend, when they fall in with the Athenian, and being favourably impressed by his conversation invite him to join them as an "expert adviser."

The problem thus differs from that of the *Republic*; the question is not the construction of an ideal Utopia, but the framing of a constitution and code which might be successfully adopted by a society of average Greeks in the middle of the fourth century. Hence the demands made on average human nature though exacting, are not pitched too high, the communion of the *Republic* is dropped. And for the same reason it is assumed all through that the regulations are carefully adapted to the particular economic and geographical conditions, though it is said that these conditions will not really suit any actual Cretan locality. If so, we must suppose that Plato, under a transparent disguise, is contemplating the actual conditions in quarters from which the Academy was more likely to receive appeals for help.

The special purpose of the work also explains why purely speculative philosophy and science are excluded from its purview. The metaphysical interest is introduced only so far as to provide a basis for a moral theology, the one matter of first-rate scientific importance touched on is the diurnal motion of the earth, and this is only hinted in connection with the practical problem of the construction of the Calendar. In compensation, the *Laws* is exceptionally rich in political and juristic wisdom, and appears, indirectly, through its influence on the law of the Hellenistic age, to have left its mark on the great system of Roman jurisprudence.

It is impossible to do more than to call attention to a few of the striking features of this great work. The ethical ideal is still that familiar from earlier dialogues. It is interesting that the demand is expressly made that all "unnatural" vices shall be completely suppressed, and that the rule of sexual life is to be monogamous marriage with strict chastity, outside the limits of marriage, for both sexes. In politics, Plato declares himself definitely in favour of a "mixed" constitution, a good government demands a balance between two principles, $\epsilon\lambda\alpha\upsilon\theta\epsilon\rho\iota\alpha$, "popular control," and $\mu\omicron\nu\alpha\rho\chi\iota\alpha$, "personal authority." Persia is an illustration of the mischief of unqualified autocracy, Athens of the evils which come from elimination of the "authoritarian" principle, and considerable care is taken in the suggested system of magis-

traces to secure both genuine "popular representation" and the proper regard for personal qualifications. The basis of society is to be agriculture, not commerce, the citizens are to be "peasant proprietors"—communism is regretfully abandoned as impracticable in a society of ordinary human beings. But the patrimony of each household is to be strictly unalienable, and differences in "personal" property are to be kept within strict bounds by what amounts to a super-tax of 100% on incomes beyond the statutory limits. Education, as in the *Republic*, is regarded as the most important of all the functions of government, it is placed under the control of a minister who is the "premier." As far as possible, the distinction between the sexes is, as in the *Republic*, to be treated as irrelevant to the educational programme.

The most striking features of the scheme are the careful attention paid to the problems of the physical training of children in their earliest infancy, and the right utilization of the child's instinct for play, and the demand, made now for the first time, that in adolescence, the young shall be taught in institutions where expert instruction in all the various subjects is co-ordinated. It is from this proposal that the "grammar school," or secondary school, has taken its origin. Though we hear no more of "philosopher-kings" the demand is still made that the members of the "Nocturnal Council," the supreme Council of the State, which is always in permanent session, and exercises a general control over administration, shall be thoroughly trained, not only in the exact sciences, but in the supreme science, which "sees the One in the Many and the Many in the One," that is, they are to be "dialecticians."

The work is full of suggestions for the practical application of science, such, for example, as that of the necessity of strictly standardizing all weights and measures, or that of basing the Calendar on a solar year (of 365 days). The object of the apparently arbitrary selection of the number of patrimonies and the scheme of sub-division of the whole society into smaller groups appears to be the practical one of making it easy to determine exactly what quatum each subdivision may justly be called on to contribute to the revenue or the defences.

At least two fundamental improvements are made on the Attic jurisprudence which Plato has adopted as the foundation of his own code. One great blot on the Heliastic system is removed by the regulations which ensure that trials for serious offences shall take place before a court which contains highly qualified magistrates, and shall proceed with due deliberation, and that there shall be provision for appeals from the primary tribunal to a "Court of Cassation." It is even more important, perhaps, that *Laws IX* by drawing a clear distinction between *βλάβη*, detriment, and *ἀδικία*, infringement of rights, lays the foundation for the discrimination between civil and criminal actions at law.

An incidental passage in the *Laws* (822 a-b) and another in the *Epinomis* (987b) definitely show that Theophrastus was right in crediting Plato with belief in the earth's motion. In the *Laws* it is said that the real orbit of each planet is a single closed curve, in the *Epinomis* the view that the "circle of the stars" communicates its motion to those of the planets is called that of men "who know but little of the subject." The allusion is to the famous theory of the celestial motions put forward by Plato's friend and associate, the great mathematician Eudoxus.

According to this, the first great "geocentric" theory in scientific astronomy, the movements of each planet can be analyzed into a combination of circular revolutions, the unmoved earth being taken as the common centre of all. What Plato asserts is that each planet has only one "proper" revolution, the remaining revolutions are apparent, not real. The implication is that these apparent revolutions of the planet must be real motions of the earth from which we make our observations. The earth is thus a planet, though not a satellite of the sun. The language of the *Epinomis*—which may be safely regarded as at least true to Plato's thought—definitely makes the sun, itself, one of the planets. We have, therefore, to think of the earth as also a planet revolving with the rest round an unseen centre. We may infer from the words of Theophrastus that Plato, like some of the Pythagoreans, held that there is a luminary, the "central fire,"

at this centre. The period of the earth's revolution would certainly be taken to be the natural day, so that the motion ascribed to the earth is equivalent to the diurnal rotation, though from Plato's point of view, it is not a rotation on an axis, but a revolution round a centre. It follows that the alternation of day and night is no longer accounted for by a rotation of the "heaven of the fixed stars." This "outermost circle" is still credited in the *Epinomis* with a revolution in the sense E to W, but its period is not specified. We need not suppose either that Plato could have specified the period or that he used it to explain any special appearances.¹

What is to Plato's credit is that he has the insight to see that, with all its attractions, the scheme of Eudoxus starts from a wrong pre-supposition, a stationary earth.

In *Laws X* Plato, for a practical purpose, creates natural theology. There are three false beliefs which are fatal to moral character, atheism, denial of the moral government of the world, the belief that divine judgment can be bought off by offerings. Plato holds that he can disprove them all. The refutation of atheism turns on the identification of the soul with the "movement which can move itself," already used in the *Phaedrus*. All motion is either communicated from without or self-initiated, and the ultimate source of all communicated motion must be self-initiated motion. The only thing which can move itself is a soul. It follows that all motion throughout the universe is ultimately initiated by souls. It is then inferred from the regular character of the great cosmic motions and their systematic unity, that the souls which originate them form a hierarchy with a "best soul," God, at their head. Disorderly and irregular motions are equally due to souls, but to bad and disordered souls, and since there are disorderly motions, it is inferred that the "best soul" cannot be the only soul.

There is no suggestion that there is a "worst soul," a "devil" or "evil world-soul," all that is said is that there *must* be one soul which is not the best, and may be more. This is Plato's way of excluding Pantheism, as incompatible with the reality of evil. The argument thus establishes at once the immortality of the soul and the existence of God. The other two heresies can now be disposed of. It is inconsistent with the goodness of the best soul to be indifferent to our conduct, and still more so to be venal. The moral government of the world is, in fact, assured by the establishment of the single principle that every soul gravitates into the society of its likes, and consequently "does and has done to it what it befits such a soul to do and have done to it." Plato thus becomes definitely the originator of the view, that there are certain theological truths which can be strictly demonstrated by reason.

It is these demonstrable truths which are subsequently named by Varro "natural" or "philosophical" theology in contradistinction to the "poetical theology," the myths related by the poets, and the "civil theology," the ritual cultus instituted by politicians. From Varro the distinction of three theologies passed to St. Augustine, and thus in the end became the foundation of the scholastic distinction between natural theology, those truths about God which can be ascertained independently of any specific revelation, and revealed theology, the further truths which are only made accessible by the Christian revelation. Since Plato's object in demonstrating his three propositions is an ethical one, he goes on to enact that the maintenance of any of them shall be a grave crime to be visited by the State with penalties ranging from a minimum of five years' solitary confinement, and with death on a second conviction. Plato is thus the inventor, so far as European society is concerned, of the proposal to make an official creed for the State and to treat dissent from it as criminal, an innovation foreign to the spirit of the Hellenic cities, in which religion was a matter not of beliefs but of cultures. Plato's last word, then, on the problem how the sensible comes to "partake" of Form is that it does so through the agency of divine goodness and wisdom. God moulds the sensible upon the pattern of the intelligible. The obvious question, how God, who is a "soul"

¹ It has nothing to do with "precession of the equinoxes," being in the wrong sense for that purpose.

not a Form, is related to "the Good" which is the supreme Form never receives discussion or solution. To answer it was to be the main business of Plotinus.

PLATONISM AFTER PLATO

Aristotle's Account of Platonism.—Since Plato refused to write any formal exposition of his own metaphysics, our knowledge of its final shape has to be derived from the statements of Aristotle, which are confirmed by scanty remains of the earliest Platonists preserved in the Neo-Platonic commentaries on Aristotle. These statements can, unfortunately, only be interpreted conjecturally. According to Aristotle (*Metaphysics*, A 987, b 18-25) Plato's doctrine of Forms was, in its general character, not very different from Pythagoreanism, the Forms being actually called Numbers. The two points on which Aristotle regards Plato as disagreeing with the Pythagoreans are, that (1) whereas the Pythagoreans said that numbers have as their constituents, the unlimited (*ἀπειρον*) and the limit (*πέρας*), Plato taught that the forms have as constituents "the One" and the "great and small", (2) the Pythagoreans had said that things are numbers, but Plato intercalated between his Forms (or Numbers) and sensible things an intermediate class of "mathematicals". It is curious, that in connection with the former difference Aristotle dwells mainly on the substitution of the "duality of the great-and-small" for the "unlimited", not on the much more significant point that the "One," which the Pythagoreans regarded as the simplest complex of unlimited and limit, is treated by Plato as itself the element of limit. He further adds that the "great-and-small" is, in his own technical terminology, the "matter," the One, the formal constituent, is a Number.

If we could be sure how much of the polemic against Number-Forms in *Metaphysics* M-N is aimed directly at Plato, we might add considerably to this bald statement of his doctrine, but unluckily it is certain that much of the polemic is concerned with the teaching of Speusippus and Xenocrates. It is not safe, therefore, to ascribe to Plato statements other than those with which Aristotle explicitly credits him. We have then to interpret, if we can, two main statements. (1) the statement that the Forms are Numbers; (2) the statement that the constituents of a Number are the "great-and-small" and "the One."

Light is thrown on the first statement if we recall the corpuscular physics of the *Timaeus* and the "mixture" of the *Philebus*. In the *Timaeus*, in particular, the behaviour of bodies is explained by the geometrical structure of their corpuscles, and the corpuscles themselves, are analysed into complexes built up out of two types of elementary triangle, which are the simplest "elements" of the narrative of *Timaeus*. Now a triangle, being determined in everything but "absolute magnitude" by the numbers which express the ratio of its sides, may be regarded as a triplet of numbers.²² If we remember then, that the triangles determine the character of bodies, and are, themselves, determined by numbers, we may see why the ultimate Forms on which the character of Nature depends should be said to be Numbers, and also what is meant by the "mathematicals" intermediate between the Forms and sensible things. According to Aristotle, these "mathematicals" differ from Forms because they are many, whereas the Form is one, from sensible things in being unchanging. This is exactly how the geometer's figure differs at once from the type it embodies and from a visible thing. There is, for example, only one type of triangle whose sides have the ratios 3:4:5, but there may be as many "pure" instances of the type as there are triplets of numbers exhibiting these ratios, and again, the geometrical triangles which are such "pure" instances of the type, unlike sensible three-sided figures, embody the type exactly and unchangingly. A mathematical physicist may thus readily be led to what seems to be Plato's view that the relations of numbers are the key to the whole mystery of nature, as is actually said in the *Epinomis* (990c).

We can now, perhaps, see the motive for the further departure from Pythagoreanism. It is clear that the Pythagorean parallelism

²² Thus the two fundamental triangles of *Timaeus* may be called the triplets (1,1,√2) (1,√3,2) respectively.

between geometry and arithmetic rested upon the thought that the "point" is to spatial magnitude what the number 1 is to number. Numbers were thought of as collections of units, and volumes, as, in like fashion, collections of points, that is, the point was conceived as a minimum volume. As the criticisms of Zeno showed, this conception was fatal to the specially Pythagorean science of geometry itself, since it makes it impossible to assert the continuity of spatial magnitude. (This, no doubt, is why Plato, as Aristotle tells us, rejected the notion of a point as a fiction.)

There is also a difficulty about the notion of a number as a "collection of units," which must have been forced on Plato's attention by the interest in "irrationalities" which is shown by repeated allusions in the dialogues, as well as by the later anecdotes which represent him as busied with the problem of "doubling the cube" or finding "two mean proportionals." "Irrational" square and cube roots cannot possibly be reached by any process of forming "collections of units," and yet it is a problem in mathematics to determine them, and their determination is required for physics (*Epin.* 990c-991b).

This is sufficient to explain why it is necessary to regard the numbers which are the physicist's determinants as themselves determinations of a continuum (a "great and small"), by a "limit" and why, at the same time "the One" can no longer be regarded as a "blend" of "unlimited" and "limit" but must be, itself, the factor of "limit." (If it were the "first result" of the blending, it would re-appear in all the further "blends"; all numbers would be "collections of one" and there would be no place for the "irrationals.") There is no doubt that Plato's thought proceeded on these general lines. Aristotle tells us that he said that numbers are not really "addible" (*ὅτι συμβαλλοῦσι ἀπὸ τοῦ ἀριθμοῦ πρὸς ἀριθμὸν*, *Met.* M 1083 a 34), that is, that the integer-series is not really made by successive additions of 1's, and the *Epinomis* (*loc. cit.*) is emphatic on the point that contrary to the accepted opinion, "surds" are just as much numbers as integers. The underlying thought is that numbers are to be thought of as generated in a way which will permit the inclusion of rationals and irrationals in the same series. In point of fact there are logical difficulties which make it impossible to solve the problem precisely on these lines. It is true that mathematics requires a sound logical theory of irrational numbers, and again, that an integer is not a "collection of units"; it is not true that rational integers and "real numbers" form a single series.

The Platonic number-theory was inspired by thoughts which have since borne fruit abundantly, but it was itself premature. We learn partly from Aristotle, partly from notices preserved by his commentators, that in the derivation of the integer-series, even numbers were supposed to be generated by the "dyad" which "doubles" whatever it "lays hold of," odd numbers in some way by "the One" which "limits" (*ἀπέχει*) or "equalises" (*ἰσάζει*), but the interpretation of these statements is, at best, conjectural. In the statement about the "dyad" there seems to be some confusion between the number 2 and the "indeterminate dyad," another name for the continuum also called the "great-and-small," and it is not clear whether this confusion was inherent in the theory itself, or has been caused by Aristotle's misapprehension.

Nor, again, is it at all certain exactly what is meant by the operation of "equalising" ascribed to the One.²³ It would be improper here to propound conjectures which our space will not allow us to discuss.

The Academy After Plato.—Though Plato's Academy produced only one later philosopher of the first order, it continued to exist as a corporate body down to the year 529 A.D. when the Emperor Justinian, in his zeal for Christian orthodoxy, closed the

²² For example, does not "contain" two 1's, 2 is not "1 and another 1", it is "the integer after 1."

²³ A full collection and examination of all the available evidence is given by L. Robin in his *Théorie platonicienne des Idées et des Nombres d'après Aristote* (1908), and an admirable exposition of the significance of the problem of the irrational for Plato's philosophy by G. Billaud in *Les philosophes géomètres de la Grèce, Platon et ses prédécesseurs* (1909). For a recent conjectural interpretation see A. E. Taylor's essay, "Forms and Numbers," in *Mind*, N.S. 140, 141.

schools of Athens and appropriated their emoluments. Plato's greatest scholar, Aristotle, finally went his own way and organised a school of his own in the Lyceum, claiming that he was preserving the essential spirit of Platonism, while rejecting the difficult doctrine of the Forms, the place of official head of the society was filled first by Speusippus, Plato's nephew (347-339 B.C.), then by Xenocrates (339-314 B.C.). Under Arcesilaus (276-241 B.C.) the Academy began its long-continued polemic against the sensationalist dogmatism of the Stoics, which accounts both for the tradition of later antiquity which dates the rise of a "New" (some said "Middle") and purely sceptical "Academy" from Arcesilaus, and for the eighteenth-century associations of the phrase "academic philosophy."

In the first century B.C. the most interesting episode in the history of the school is the quarrel between its President, Philo of Larissa and his scholar Antiochus of Ascalon, of which Cicero's *Academica* is the literary record. Antiochus, who had embraced Stoic tenets, alleged that Plato had really held views indistinguishable from those of Zeno of Citium, and that Arcesilaus had corrupted the doctrine of the Academy in a sceptical sense. Philo denied this. The gradual rapprochement between Stoicism and the Academy is illustrated from the other side by the work of Stoic scholars like Panaetius of Rhodes, and Poseidonius of Apamea, who commented on Platonic dialogues and modified the doctrines of their school in a Platonic sense.

The history of the Academy after Philo is very obscure, but early in our era we meet with a popular literary Platonism of which the writings of Plutarch are the best example. This popular Platonism insists on the value of religion, in opposition to Epicureanism, and on the freedom of the will and the reality of human initiative, in opposition to the Stoic determinism, a further characteristic feature, wholly incompatible with the genuine doctrine of Plato, is the notion that matter is inherently evil and the source of moral evil.

Genuine Platonism was revived in the third century A.D. at Rome, and independently of the Academy, by Plotinus. His Neo-Platonism (q.v.) represents a real effort to do justice to the whole thought of Plato, but there are two sides of it which inevitably, in the changed conditions, fell into the background, the mathematical physics and the politics. The third century A.D. had no understanding for the first, and the Roman Empire under a succession of military chiefs no place for the second. The doctrine of Plotinus is Platonism seen through the personal temperament of a saintly mystic, and with the *Symposium* and the teaching of the *Republic* about the "Form of Good" always in the foreground. Plotinus lived in an atmosphere too pure for sectarian polemic, but in the hands of his successors, Neo-Platonism was developed in conscious opposition to Christianity. Porphyry, his disciple and biographer, was the most formidable of the anti-Christian controversialists, in the next century, "Platonists" were among the allies and counsellors of the Emperor Julian in his ill-advised attempts to invent an Hellenic counterpart to Christianity.

Early in the fifth century, Neo-Platonism flourished for a short time in Alexandria (which disgraced itself by the murder of Hypatia in 415) and captured the Athenian Academy itself, where its last great representative was the acute Proclus (A.D. 410-485). The latest members of the School, under Justinian, occupied themselves chiefly with learned commentaries on Aristotle, of which, those of Simplicius are the most valuable. The doctrine of the school itself ends in Damascus with complete agnosticism.

Influence on Christian Thought.—Traces of Plato are probably to be detected in the Alexandrian *Wisdom of Solomon*; the thought of the Alexandrian Jewish philosopher and theologian Philo, at the beginning of our era, is at least as much Platonic as Stoic. There are, perhaps, no certain marks of Platonic influence in the New Testament¹, but the earliest apologists (Justin, Athe-

nagoras) appealed to the witness of Plato against the puerilities, and indecencies of mythology. In the third century Clement of Alexandria, and after him, Origen, made Platonism the metaphysical foundation of what was intended to be a definitely Christian philosophy. The Church could not, in the end, conciliate Platonist eschatology with the dogmas of the resurrection of the flesh and the final judgment, but in a less extreme form the Platonizing tendency was continued in the next century by the Cappadocians, notably St. Gregory Nyssen, and passed from them to St. Ambrose of Milan. The main source of the Platonism which dominated the philosophy of western Christian divines through the earlier Middle Ages, were, however, Augustine, the greatest thinker among the Western Fathers, who had been profoundly influenced by Plotinus, read in a Latin version, before his conversion to Christianity, and Boethius, whose wholly Platonist vindication of the ways of Providence in his *Consolatione Philosophiae* was the favourite "serious" book of the Middle Ages.

A further powerful influence was exerted by the writings of the so-called Dionysius the Areopagite, which laid down the main lines of mediaeval mystical theology and angelology. These works are, in fact, an imperfectly Christianized version of the speculations of Proclus, and cannot date before the very end of the fifth century A.D. at the earliest, but they enjoyed an immense authority based on their attribution to an immediate convert of St. Paul.

After their translation into Latin in the ninth century by Johannes Scotus Erigena, their vogue in the West was as great as in the East. Apart from this theological influence, Plato dominated the thought of the earlier Renaissance which dates from the time of Charlemagne in another way. Since the West possessed the philosophical writings of Cicero, with the Neo-Platonic comment of Macrobius on the *Somnium Scipionis*, as well as the Latin translation of the first two-thirds of the *Timaeus* by Chalcidius, with his commentary on the text, and versions, also, at least of the *Phaedo* and *Meno*, whereas nothing was known of the works of Aristotle except Latin versions of some of the logical treatises, the Middle Age, between Charlemagne and the beginning of the thirteenth century, when the recovery of Aristotle's physics and metaphysics from Moors, Persians, and Jews began, was much better informed about Plato than about Aristotle, in particular in the various "encyclopaedias" of this period, it is the *Timaeus* which forms the regular background.

The thirteenth century saw a change. Aristotle came to displace Plato as "the philosopher," partly in consequence of the immediately perceived value of his strictly scientific works as a storehouse of well-digested natural facts, partly from the brilliant success of the enterprise carried through by St. Thomas Aquinas, the reconstruction of philosophical theology on an Aristotelian basis. Plato is, however, by no means supplanted in the Thomist system, the impress of Augustine on Western thought has been far too deep for that. Augustine's "exemplarism," that is, the doctrine of Forms in the version, ultimately derived from Philo of Alexandria, which makes the Forms "creative thoughts" of God, is an integral part of the Thomist metaphysics, though it is now denied that the exemplars are themselves cognizable by the human intellect, which has to collect its "forms," as best it can, from the data of sense.

Directly or through Augustine, the influence of Plato, not only on strictly philosophic thought but on popular ethics and religion, has repeatedly come to the front in ages of general spiritual quickening, and shows no signs of being on the wane.

Two "revivals" in particular are famous. The first is that of the 16th century, marked by the Latin translation of Marsilio Ficino and the foundation of Lorenzo dei Medici's fantastic Florentine Academy. What was revived then was not so much the spirit of Plato as that of the least sober of the Neo-Platonists, the influence of the revival was felt more in literature than in philosophy or morals, but in literature its importance may be measured by the mere mention of such names as Michelangelo, Sidney, Spenser.

In the 17th century, Plato, seen chiefly through the medium of Plotinus, supplied the inspiration of a group of noble thinkers who were vindicating a more inward morality and religion

¹We may perhaps detect it in John i 18 if the true text is "the only begotten God (*μονογενὴς θεός*) which is in the bosom of the Father." This may be an echo of the phrase used in the *Timaeus* (*ἑστὶν αὐτῷ τὸ οὐρανόθεν*) "A God apprehensible to sense" (one and only begotten" (*μονογενὴς ὁ θεός*)). But it is not safe to assert it.

were had for children since they deprived them of the healthful work for play which are as essential elements in a child's education as study. The platoon school returned opportunities for work and play to children by providing schools containing not only classrooms but well-equipped shops, science rooms, drawing and music studios, cooking rooms, auditoriums, playgrounds and gymnasiums. The traditional public school operated on a "peel-and-plan" plan of operation, i.e., on the principle of reserving a school seat for the exclusive use of one child during the entire year. When the children left these seats to go to shops or playgrounds the seats remained vacant. Under such a plan there were seldom enough seats, playgrounds or shops to accommodate all the children in a city at one time.

Under the platoon plan, on the contrary, all facilities in the school—classrooms, auditoriums, gymnasiums, shops and laboratories—were put to use every hour of the day. The school was divided into two parts, each having the same number of classes and each containing all the eight or nine grades. While one of the schools was in classrooms, the other was in special activities, auditoriums, playgrounds and gymnasiums. This meant that only half the usual number of classrooms was needed.

BIOGRAPHY.—R. S. Bourne, *The Gory Schools* (1916); Charles L. Spain, *The Platoon School* (1924); William Wirt, "Creating a Child World," *The Platoon School*, 1: 4-7 (Jan. 1927). (A. B. A., X.)

PLATT, CHARLES ADAMS (1861-1933), U.S. architect, was born in New York, N.Y., on Oct. 16, 1861, and educated in the National Academy of Design, and in Paris under Gustave Boulanger and Jules J. Lefebvre. At first he intended to become a painter and etcher, but the outcome of a visit to Italy was a book, *Italian Gardens* (1892). This explained his adoption of architecture, and his work showed the marked influence of Italian form. He designed many private houses and gardens in addition to public buildings, among the latter being the Maxwell Memorial library, Rockville, Conn. (1917), the Freer Gallery of Art, Washington, D.C. (1918), the library, Connecticut College for Women, New London, Conn. (1922); the agricultural building, University of Illinois, Urbana, Ill. (1923); and the Lowell memorial fountain, New York, N.Y.

See *Monograph of the Work of Charles A. Platt*, with an introduction by Royal Cortissoos (1913).

PLATT, THOMAS COLLIER (1833-1910), U.S. politician, born in Owego, N.Y., July 15, 1833, studied at Yale university, New Haven, Conn., 1849-52. He became a banker and speculated in lumber. In the 1860s Platt was chairman of the Tioga county (N.Y.) Republican committee, and in 1877, after having been elected for two terms to the U.S. house of representatives, he became chairman of the state Republican convention. Elected to the U.S. senate in Jan. 1881, Platt soon resigned, and within ten years he became the Republican boss of the state. Although he again served in the U.S. senate, his political power waned steadily after about 1903. He died in New York city, March 6, 1910.

PLATTE, a river system of Colorado, Wyoming and Nebraska, tributary to the Missouri river, which it enters immediately north of Plattsmouth, Neb., 18 mi. below Omaha, in about 41° 3' N. latitude. Including the North Platte it is about 943 mi. long from its headwaters, with a drainage basin for the entire flow from the north, the most important being the Loup and the Elkhorn. The main stream west of Kearney, as well as the North and the South Platte, are extensively used for irrigation.

See R. P. Teale, "Water Rights in Interstate Streams," U.S. Dept. of Agriculture Bulletin No. 157 (1905) and J. C. Stevens, *Surface Water Supply of Nebraska* (1909).

PLATTEVILLE, a city of Grant county, Wis., U.S., 20 mi. from the southwest corner of the state, on federal highway 151; and served by the Chicago and North Western and the Chicago, Milwaukee, St. Paul and Pacific railways. Pop. (1950) 5,718, (1940) 4,761. It is in a sand and lead mining region, and is the seat of a state teachers college. The city was settled about 1877 and incorporated in 1880.

PLATTSBURG, a city of northern New York, U.S., on the west shore of Lake Champlain, is on federal highway 9 and is

served by the Delaware and Hudson railway and Colonial Airlines. Pop. (1950) 17,726, (1940) 16,351, (1930) 13,349 by the federal census. Plattsburg is surrounded by beautiful scenery, the broad, island-studded lake in front, with the Green mountains beyond and, on the southern horizon, the distant Adirondacks. South of the city is Plattsburg barracks, an army post established in 1815, where thousands of reserve officers were trained during World War I. After World War II the first U.S. veterans' university was established on the site of the barracks in 1940, this institution later became a unit of the State University of New York. Plattsburg is a recreational center and manufactures paper specialties, razor blades and wallpaper.

Plattsburg was founded by Zephaniah Platt (1740-1807), who brought a colony from Long Island. It was incorporated as a village in 1795 and as a city in 1902. The opening naval engagement of the Revolution (a victory for the British) took place at Valcour Island, 5 mi. SE of Plattsburg, on Oct. 11, 1776. In the War of 1812 Plattsburg was the headquarters of the U.S. army on the northern frontier. On Sept. 6, 1814, the village was besieged by land, and on Sept. 11, the "Commodore Thomas Macdonough" defeated the invading fleet.

PLATTSMOUTH, a city of eastern Nebraska, U.S., on the Missouri river, at the mouth of the Platte, 27 mi. below Omaha, the county seat of Cass county. It is on federal highways 34, 73 and 75, and is served by the Burlington Route and the Missouri Pacific railway. Pop. (1950) 4,890, (1940) 4,268. The city ships grain and cattle, and has large railroad shops, flour mills, garment factories, a cannery and other plants. It is one of the oldest settlements of the state. Nebraska Masonic home for the aged is located there. A trading post licensed by the U.S. government was opened there in 1853, a town was platted in 1854, and the city was incorporated in 1855.

PLATYHELMINTHES or **PLATODARIA**, a phylum of invertebrate animals containing soft-bodied creatures which are bilaterally symmetrical and usually somewhat flattened in shape, and in which there is no true "coelom" or perivisceral cavity and no true (metameric) segmentation. The animals contained in this group (flatworms) are the simplest and probably the most primitive of those in which the tissues and organs of the body are developed from three, instead of two, original embryonic layers.

FIG. 1.—SECTIONAL PORTION THROUGH THE BODY OF A TREMATODE (PARACOELOMUS). SHOWING STRUCTURE OF TISSUES.

The musculature of the body is mainly peripheral, consisting of layers of transverse, longitudinal and often also oblique muscle-fibers running beneath the epidermis.

These muscles render the body capable of extreme elongation and contraction, and often of surprising variability in shape.

Anterior and posterior ends of the body can usually be distinguished, the animals having a definite direction of locomotion, accompanied by a greater degree of specialization of the anterior extremity. Dorsal and ventral surfaces are also generally distinguishable, the latter being that on which the animal creeps, and on which the oral and genital apertures are commonly situated.

ated. In the parasitic flatworms special clinging organs are generally developed, in the form of muscular suckers, often supplemented by cuticularized hooks or spines.

An alimentary canal may or may not be differentiated. When present, it may either be a simple saclike organ or may be variously branched. With very few exceptions, its only aperture is the mouth, which may be situated subterminally, near the an-

FIG. 2.—EXCRETORY SYSTEM OF A PLATYHELMINTH.

Below, diagram of a portion of the excretory system showing branching ducts ending in flame cells. Above, a single flame cell more highly magnified.

tenor end, or much further back, sometimes even behind the middle of the body. The mouth may be surrounded by an oral sucker, and usually a highly muscular, often protrusible pharynx intervenes between mouth and intestine.

The main ganglia of the nervous system (the "brain") and the chief sense organs are generally concentrated towards the anterior end. In addition to tactile papillae or special sensory cilia, "eye-spots" or ocelli are frequently present in free-living forms, and sometimes in the free-living larval stages of parasitic forms. In certain free-living flatworms *statocysts* (saclike organs containing minute calcareous nodules or *statoliths*) and ciliated pits, probably sensory in function, also occur.

There is no blood-vascular system or haemocoel. The excretory organs consist of a branching system of canals ending internally in "flame-cells." These are minute pyriform structures containing cilia which keep up a constant flickering movement. The main collecting vessels of the system open to the exterior by one, two or many pores.

The Platyhelminthes are, with rare exceptions, hermaphroditic animals, each individual being functionally both male and female. The reproductive system is usually very complex. The male organs consist essentially of one or more (often very numerous) testes, whose ducts are usually connected with a protrusible intro-mittent organ (penis or cirrus). The essential organs of the female apparatus are an ovary (sometimes multiple ovaries) and a tubular duct communicating with the exterior. The arrangement of the parts of the female system is subject to great variation in different groups. Sometimes the same duct functions in turn as a vagina or fertilization canal, as a uterus or reservoir for fertilized eggs, and as an oviduct by which the eggs reach the exterior. In some cases (most cestodes) the only communication with the exterior is a vagina, which is connected internally with an oviduct leading from the ovary to a saclike uterus, but does not serve for the expulsion of eggs. In such forms the eggs are either shed only by the dehiscence of the wall of the uterus

and of the body wall, or by a special (temporary or permanent) birth-pore. In almost all flatworms there is a yolk gland or vitellarium (often multiple vitellaria), producing yolk cells which form nutritive material for the developing embryos. The vitellarium, in the most primitive forms, appears to be developed as a sterile portion of the ovary. There is also usually a "shell-gland," which usually secretes adhesive material for fastening eggs together or to a substratum. The ducts of these glands open into the oviduct or into a specialized portion of it called the *ootype*. The external apertures of the male and female ducts are sometimes separate, but frequently both ducts open into a common "genital atrium," which is often muscular. Not infrequently a special duct and pore for copulatory purposes are present.

The Platyhelminthes are extremely widely distributed, free-living forms occurring in almost every kind of environment—in shallow or deep water, both fresh and marine, and on land—while parasitic forms occur on or in animals of almost every class. The free-living forms usually feed actively on small animals or plants. The parasitic forms show various degrees of modification in habits, some being external parasites and feeding on mucus or other matter derived from the skin of their hosts, while others are internal parasites and feed on partly digested food or on body fluids. Among the latter class some are without special digestive organs and can only feed by the absorption of liquid nourishment.

The phylum is usually considered to include three main divisions or classes: (1) Turbellaria (including Temnocephalidae), the majority of which are free-living, but some parasitic. This group is probably nearest to the primitive ancestral form. (2) Trematoda (flukes), all of which are wholly or partly parasitic either upon or within other animals. (3) Cestoda (tapeworms), all of which are wholly endoparasitic. See TAPEWORMS, TREMATODES, TURBELLARIA.

(H. A. B. X.)

PLATYPUS, a remarkable Australian aquatic mammal belonging to the primitive subclass Monotremata (*q v*). The duck-billed platypus (*Ornithorhynchus anatinus*), the only species, is oviparous, two eggs, $\frac{1}{2}$ in. long and $\frac{1}{4}$ in. wide, each enclosed in a strong, flexible, white shell, are produced at a time. The animal shows many primitive features, there are no true teats in the female, the milk glands being probably modified sweat glands, the body temperature is relatively low. The platypus inhabits the streams and rivers of southeast Australia and Tasmania. About 20 in. long, it is clad in short, dense fur of a deep brown above, paler below. There are no teeth in the adult, their purpose being served by horny prominences, two on each side of each jaw. The broad horny muzzle is very beaklike. In the cheek are capacious pouches. The limbs are short and strong, each with five claw-bearing toes. In the forefeet, the web extends far beyond the ends of the claws, but it can be folded back on the palm when the animal comes out on to the land. On the heel of the male is a movable horny spur, perforated by a canal which communicates with a poison-gland. The platypus forms deep burrows in the banks, in which it sleeps and brings up its young, the entrance being under water. The food consists of aquatic insects, Crustacea and worms. The animal is nocturnal.

PLATYPUS (ORNITHORHYNCHUS ANATINUS), AN EGG-LAYING MAMMAL.

PLATYRHINE MONKEY.

PLAUN.

twin spires, was*restored in 1886. The town hall dates from about 1550, and the old castle, Hradschin, is now a law court. Plauten manufactures embroidered white goods and makes lace. It manufactures much of the machinery used in the town and it has a trade in coal, yarn and cattle.

PLAUTUS, TITUS MACCIUS (originally, perhaps, Maccus, cf. *Asin.* Pro 11), the great comic dramatist of ancient Rome, was born at Sarsina in Umbria according to the testimony of Festus, who calls him *Umbri Sarsinas*, and Jerome. The date of his death was 184 B.C. (Cicero, *Brutus*, xv 60). The date of his birth depends upon an inference based on the statement of Cicero (*De senectute*, xiv 50) that he was an old man, when he wrote his *Truculentus* and *Pseudolus*. The latter play was produced in 191 B.C., hence we get 254-251 B.C. as the approximate date of his birth. The only record that we possess as to his life is that contained in Aulus Gellius iii 3, 14 (based on Varro), the historical character of which is doubted by Leo (*Plautinische Forschungen*, ch. 11). The chief fact that emerges is that he left his native Umbrian home and settled as a *peregrinus* at Rome, where, after earning some money and losing it again, he took to writing plays.

The Plays.—His literary activity may well have begun somewhat late in life, for it must have taken him a long time and much hard study to acquire the mastery of Latin and Greek which his dramas attest. The main body of his extant works belongs, so far as can be ascertained from the scanty evidence which we have, to the last 20 years of his life, 206-204 B.C. is the approximate date of the *Miles Gloriosus*, cf. line 211 seq., *quod bini custodes . . . occubant* (present tense), which alludes to the imprisonment of Naevius. Of the extant plays the *Castellaria* and the *Stichus* must be associated with the *Miles* as comparatively early works, for the former was clearly produced before the conclusion of the Second Punic War, see x 201 seq.; and the *Stichus* is proved by its didascalia to have been produced in 200 B.C. The *Pseudolus* and the *Truculentus* fall within the last seven years of his life, and the *Trinummus* is later than 194 B.C., cf. x 990 *novi aediles*.

The dates of the other extant plays are uncertain. An interesting attempt to place them in chronological order according to the proportion in them of scenes written in lyrical metres and set to music (*cantica*) has recently been made by W. B. Sedgwick (*Classical Review*, xxxix, 1925, p. 55 seq.). It is at any rate not improbable that the poet gave greater scope to his musical innovation (see below) as his command over language and metres developed and the success of his experiment became assured. The titles of the other extant plays are (in alphabetical order) *Amphitruo*, *Asinaria*, *Aulularia*, *Bacchides* (later than the Epidicus, see l. 214), *Capitoli*, *Casina*, *Curculio*, *Epidicus*, *Menaechmi*, *Mercator* (later than the *Rudens* according to F. Marx and E. Frankel, but regarded as one of the earliest plays by F. J. Enk in *Memnosyne*, lit.), F. A. Wright in *Broadway Translations*, and W. Beare in *Classical Review* xlii, 1928, pp. 206 and 214 seq.), *Mostellaria*, *Persa*, *Poenulus*, *Rudens* (probably first acted 192 B.C.), *Vidularia* (existing only in a fragmentary condition in the codex Ambrosianus). Some of these may possibly be earlier than 204 B.C., and it seems *a priori* likely that the 35 other Plautine plays known to us only by their titles and a few fragmentary quotations were not all written within the last 20 years of the poet's life.

Indebtedness and Originality.—The plays of Plautus are based on Greek originals of the New Comedy, of which one complete specimen is extant. But Plautus was not a mere translator. This was shown by K. M. Westaway (*The Original Element in Plautus*, 1917), and has been recently demonstrated in detail by E. Frankel (*Plautinische Studien*, 1922), who calls attention to certain mannerisms as evidence of unmistakable Plautine additions to the Greek texts, and also points out the originality of the Roman in the introduction of a musical element into his plays (see below). On the other hand, there are passages in which he does not hesitate to take over from his originals, allusions which can hardly have been intelligible to a Roman audience, e.g., the reference to Stratonice, a musician of the time of Alexander the Great (*Rudens*, 932), and in the delineation of character we have

no reason to suppose that he improved on his models (cf. Aul. Gell. ii 23). Even the bulk of the prologues may be of Greek origin, though certain passages in them must have been added by Plautus, and other passages (e.g., *Casina* 5-20) are post-Plautine. And where Plautus varies his plot on lines of his own by amalgamating the plots of two distinct Greek comedies (e.g., in the *Miles* and the *Poenulus*) the result is generally not happy, the romanization of the plays by way of allusions to towns in Italy, to the streets, gates and markets of Rome, to Roman magistrates and their duties, to Roman laws and the business of Roman law courts, banks, comitia and senate, etc., involves the poet in all the difficulties of attempting to blend two different civilizations. The inconsistency of his attitude is shown by his use, side by side, of the contemptuous expressions *barbarus* (applied to the Romans) and *pergraeus* (applied to the Greeks). In some passages the poet seems to take delight in casting dramatic illusion to the winds (e.g., *Pseudolus*, 720, *Poenulus*, 550).

But as an adapter for the Roman stage Plautus is not less than masterly. His command of Latin is such that his plays read like original works, and it may be at least said that some of his characters stand out so vividly from his canvases that they have ever since served as representatives of certain types of humanity, e.g., Euclio in the *Aulularia*, the model of Molière's miser. Alliteration, assonance, plays upon words and happy congeries of new terms, give his plays a charm of their own. "To read Plautus is to be once on all disabused of the impression that Latin is a dry and uninteresting language" (Skutsch, in *Die Kultur der Gegenwart*, 1905). It is a mistake to regard the Latin of Plautus as "vulgar" Latin. It is essentially a literary idiom, based upon the language of intercourse of the Roman society of the day (cf. Cic. *De oratore*, iii 12, 45).

The Characters in his plays are the stock characters of the New Comedy, and they remind us also of the standing figures of the *Fabulae Atellanae* (Maccus, Bucco, Dossennus, etc.). We may miss the finer insight into human nature and the delicate touch in character-drawing which Terence presents to us in his reproductions of Menander, but there is wonderful life and vigour, and considerable variety in the Plautine embodiments of these different types. Their language is often coarse; and there is some deliberate obscenity in it, but not so much as has been discovered by Gurlitt and introduced into his German translation (1920-22). And the careful reader will take note of occasional touches of serious thought (no doubt derived from the Greek originals), as in the enumeration of the ten deadly political sins (*Persa*, 555 seq.) and allusions to ethical philosophy (*Pseud* 972 seq., *Stich*, 124; *Trin.* 305 seq., 320 seq., 363 seq., 447; *Rud.* 767, 1235-1248, etc.). The *Capitoli* is the story of the heroic self-sacrifice of a slave. The *Amphitruo* is a mythological burlesque. But most of his plays depend for their main interest in intrigue, such as the *Pseudolus*, *Bacchides*, *Mostellaria*. In the *Menaechmi* and as a subordinate incident in the *Amphitruo* we have a comedy of errors.

Metres.—In the metrical structure of his plays Plautus introduced an important innovation. The New Comedy of Greece had confined itself for the most part to the metres of dialogue. Plautus took the bold step of transposing whole scenes into metres suitable for singing to the accompaniment of the flute (*cantica*), and to other scenes he gave a quasi-operatic character by the use of recitative. But the *cantica* are not mere inserts or accessories, like the songs introduced in the Shakespearean drama; they form integral parts of the action, which would often be unintelligible without them (see Fränkel [op. cit.] whose theory is a development of that of Leo in *Die plautinischen Cantica* and *die hellenistische Lyrik*, 1897). The metres employed were, of course, not invented by Plautus; they are of Greek origin and are common to Roman tragedy and Roman comedy, but Plautus gave them a new development and a wider scope. Further light is thrown upon the immediate source of these Plautine metres by J. H. O. Immisch (*Zur Frage der plaut. Cantica*, in *Berichte der Heidelb. Akad.*, 1923). The Plautine metres are wonderfully varied, and the textual critic does well not to attempt to limit the possibilities of original metrical combinations and developments in the Roman

comedian

Reputation.—Plautus was a general favourite in the days of republican Rome. Cicero, though he found fault with the iambs of the Latin comedians generally as affected "slovenly" (*Orator* iv 184), admired Plautus as *elegant, urbanus, ingeniosus, facetus* (*De offic* i, 29, 104). To the fastidious critics of the Augustan age, such as Horace, he seemed rude (*cf. Ars Poetica*, 270-274), just as Addison declared Spenser to be no longer fitted to please "a cultivated age." In another passage (*Epist* ii 1 170-176) Horace accuses him of clumsiness in the construction of his plays and the drawing of his characters, and indifference to everything except immediate success, *gestit enim munum in loculos demittere, post hoc securus cadat on recto stet fabula toto*. That there are many inconsistencies and signs of carelessness in his work has been proved in detail by Langen. But that he found many admirers, even in the Augustan age, Horace himself bears witness (*ibid* i 58), where he says that Plautus was regarded as a second Epicharmus. Plautus *ad exemplar Sculi propterea Epicharmi*, *cf. Varro's* statement (*in Praean* ix 32), *donde ad Sculos se applicavit*. It is possible that Plautus may have been working on the lines of the old comedy in the tell-tale names which he is so fond of inventing for his characters such as Polymachoroplages (*Pseud* 988), Pyrgopolonices (*Mil* 56), Thesaurochrysochrydises (*Capt* 285)—names which stand in remarkable contrast to the more commonplace Greek names employed by Terence.

In the middle ages Plautus was little regarded, and 12 of his plays (*Bacchides*—*Truculentus*) disappeared from view until they were discovered (in the ms called *D*) by Nicholas of Treves in the year 1429. But after the revival of learning Plautus was re-estimated, and took rank as one of the great dramatists of antiquity, *cf. Shakespeare, Hamlet*, II, ii, 420, where Polonius says "The best actors in the world . . . Seneca cannot be too heavy nor Plautus too light."

Influence on Modern Literatures.—A comprehensive view of the widespread influence of Plautus on modern literatures is given by Reinhardtsoettner, *Spätere Bearbeitungen plautinischer Lustspiele* (1886). Many adaptations for the Italian stage were produced between the years 1486 and 1550, the earliest (the *Menaechmi*) under the direction of Ercole I, duke of Ferrara. From Italy the practice spread to France, Spain, England and other countries.

Of English plays the interlude called *Jack Juggler* (between 1547 and 1553) was based on the *Amphitruo*, and the lost play called the *Historie of Error* (acted in 1577) was probably based on the *Menaechmi*; Nicholas Udall's *Ralph Royster Doyster*, the first English comedy (acted before 1551, first printed 1566), is founded on *Miles Gloriosus*, Shakespeare's *Comedy of Errors* (about 1591) is an adaptation of the *Menaechmi*, and his Falstaff may be regarded as an idealized reproduction or development of the braggart soldier of Plautus and Terence—a type of character which reappears in other forms not only in English literature (e.g., in Shakespeare's Parolles and Ben Jonson's Captain Bobadil) but also in most of the literatures of modern Europe. Shakespeare's

Trinummus by Brnx (5th ed., 1909), other plays in Macmillan's Classical Series and the Pitt Press Series. Leucon, Gonzalez Lodge's *Lexicon Plautinum* (nearing completion and indispensable). Syntax, Lindsay, *Syntax of Plautus* (1907). Metre and Prosody, Lindsay, *Early Latin Verse* (1902). Vollmer, *Römische Metrik* (1923); and *Ueber die sogenannte Jambenkurzung* (1924). Sonnenschein in *What is Rhythm?* (1925, ch vi). E. Frankel's *Iktus und Akzent im lateinischen Sprechvers* (1928) is an attempt to show that in the dialogue metres, as distinct from the metres set to music, the verse-stress (*ictus metricus*) nearly always coincides with a genuine speech-accent, or at any rate corresponds to some modification of accentuation or intonation. Translations: English prose by P. Nixon in the Loeb Series (1916-24; 2 vols still to come); English verse by Wright and Rogers in *Broadway Translations*—select plays (1923).

PLAY: see DRAMA

PLAYA (a Spanish word meaning "shore"), the name applied in America to a level plain formed of the deposits of a river which has no outlet to the sea or a lake. If at seasons of high water a river floods any area and temporarily converts it into a lake, which subsequently dries up in hot weather, the tract thus left dry is called a playa. The barren Black Rock desert in north-western Nevada, about 100m in length by 15 in breadth, is typical.

PLAYER-PIANO, a piano equipped with a mechanical device for automatically playing written music or for reproducing the playing of a pianist. All types of player-piano mechanism are operated by utilizing the difference between external and internal air pressures. In fig 1, the tracker-bar, T, with its 83 holes, is represented as being closed by the paper roll, R, which lies closely against it. Some of the air has been extracted from the duct, D, and from the chamber, C, by means of an air-exhaust to which they are connected. There is a very tiny vent, V, which allows air from the tracker duct to leak into the chamber. A disk, K, closes the chamber from the outer air, being held down because the air in C, is at a lower pressure than normal. The pneumatic, B, is full of air at normal atmospheric pressure and is open to the external air by means of the port, A.

Should a hole in the paper come into line with any hole in the tracker-bar, the external air rushes into the duct and lifts the pouch, P, which is simply a circular piece of soft kid about 4in in diameter, and bigger than K. Hence it lifts K, connecting the pneumatic with the partial vacuum, C, and disconnecting it from the external air by closing the port A. The air in B spreads to C and, the external pressure on the surface, S, being greater than the reduced pressure inside, the pneumatic collapses suddenly, the movable leaf rising and lifting with it the pilot, L, which operates the piano action.

The pneumatic remains collapsed until paper again blocks the hole in the tracker-bar. The air in D then leaks through into C and can no longer hold up the pouch, which falls back into position and allows K to close the chamber C again, at the same time opening the pneumatic to the external air at A. The external and internal pressure on S now being the same, the pneumatic re-inflates and allows the pilot to drop back into position.

In the days of heavy and clumsy valves it was difficult to provide the necessary power to lift them rapidly without hard pedalling and consequent loud tone. To overcome this defect the more expensive player action was provided with an additional (or primary) valve of light construction, easily lifted by the rush of air when a hole was opened on the tracker-bar. Its lifting admitted air to the other and heavier valve, through the port O, operating the striking pneumatic as previously described. Both single and double valve systems are still in use.

The interior of the player action is maintained in a steady state of reduced pressure by forcing the pedal, F, to open the exhaust, X (fig 2). This allows all the interior air to spread itself into X past L, a flat strip of well-tanned leather, lying over holes A in spring, G (about 12lb in strength), then closes the exhaust, expelling the air via another flap valve, Z. A strong spring, A, is always trying to open the equalizer, E, but is prevented from so doing when the external air pressure is much greater than the reduced pressure inside. When, however, there is not much difference between the external and internal pressures, the spring can open and in so doing allows air to spread into it from the interior. The effect is to reduce the internal pressure

improved rather than on the *Mostellaria*.

BIBLIOGRAPHY.—Standard Texts and Editions with Notes: Texts by Goetz and Schoell (*editio minor*, 1893-1907), by Leo (1895-96), by Lindsay (1904-05). With notes *Capituli*, by Lindsay (1900), by Brnx (6th ed., 1910); *Menaechmi*, by Brnx (5th ed., 1912), *Miles* by Lorenz (2nd ed., 1886), by Brnx (3rd ed., 1901); *Mostellaria* by Lorenz (2nd ed., 1883), by Sonnenschein (2nd ed., 1907); *Pseudolus* by Lorenz (1876), *Rudens* by Sonnenschein (1891, ed. min., 1901);

MECHANISM OF THE PLAYER-PIANO THE FIGURES AND LETTERS ARE EXPLAINED IN THE TEXT

once more to such an extent that the equalizer begins to collapse. Its constant to-and-fro motion enables a steady amount of reduced pressure to be maintained in the interior channels, despite unsteady working of the pedals.

Controls.—The simplest method of operating the “soft” and “sustaining” pedals is to connect the ordinary mechanism of the piano, by suitable levers, to finger controls in front of the keyboard. Many manufacturers prefer to control the distance from the hammers from the strings as shown in fig. 3. A button, B, opens a gate, G, when pressed down. This admits air to a pouch, P, which lifts the valve lying above it, and puts the pneumatic, N, into communication with a partial vacuum, V, thus collapsing it and causing it to lift the hammer rail, H, which softens the tone by giving the hammerhead less distance to travel towards the string, S.

A similar device withdraws all the dampers from the strings. This being a heavier task than shifting the hammers, a larger pneumatic has to be employed, and two valves instead of one. Music rolls are provided with an additional hole at the left-hand edge, which works the lifting of the dampers, if desired.

Change of power, in addition to the means above described, is provided by varying the strength of the blow given to the hammer. Fig. 4 shows how the normal amount of reduced air is altered by interposing a pneumatic, N, between the main exhaust, E, and the small playing pneumatics. Pressing a button (as in fig. 3), air is allowed to enter at A, the pressure from which lifts the pouch, P, and with it the valve, D. This closes the large hole, L, and leaves only the aperture, K, over which lies a knife-cutter valve, J, so called because it closes like the blade of a pen-knife. The spring, S, is of such strength that it governs the amount of air passing through to the bellows, hard pumping closing N and therefore closing the aperture K and preventing loud playing.

A slight alteration of fig. 4 would give a fair representation of the automatic Accenting Device, which is worked from marginal perforations in the music roll. The valve disk, D, is moved to the other side of the hole, L, keeping it normally closed and softening the tone until a marginal perforation allows air to rush towards P. The pouch lifts the valve, opens L, and accents the note.

The pedals also provide sufficient power to work the spool

which draws the music roll over the tracker-bar. Five pneumatics of the type shown in fig. 5 are fixed at equal angular distances upon a crank-shaft, C, each one collapsing in turn and so driving the shaft round steadily. Collapse is effected when the hollow slide, S, is covering both of the ports A and B, for the pneumatic is then in direct communication with the main exhaust, through E. As the crank-shaft is thus moved round, the slide is raised, and no longer covers both ports. External air is admitted to the pneumatic, and the collapse of one of its neighbours provides the power to lower its slide and again get into communication with the main exhaust.

All communication between motor and exhaust is by way of a governor pneumatic, powerful pedalling tends to collapse it, but directly this happens a knife-valve partly closes the passage-way (as in fig. 4), and thus prevents the motor from “tracing.” Variation in tempo is secured by deliberately altering the size of the passage-way within an enclosure known as the Tempo Box. The shape of the slot is usually as shown in fig. 6, over which passes a slide, S. When half the area of the slot is covered, the speed of the motor is half its maximum, and so on, the slide being worked mechanically from the control board.

The holes in the paper roll being so close together, it is essential that they should track correctly, despite the effects of wear and weather. Correct tracking is controlled in ways which vary in detail, but usually depends upon the action of two pneumatics, kept under exhaust. Holes in the tracker-bar are so placed as to be uncovered when (and only when) the roll goes to one side, letting air into one of the pneumatics and causing it to open slightly, taking with it either tracker-bar or spool.

Reproducing Pianos.—The “reproducing” instruments are in a separate class, designed to reproduce faithfully all the shades of tempo and expression made by well-known pianists. All control is rightly withdrawn from the operator when using the specially cut rolls, but the same instrument may be used for ordinary rolls by putting the reproducing mechanism out of action. Additions to the normal player mechanism are mostly for the purpose of controlling more completely the comparative loudness or softness of individual notes. To do this effectively it is necessary to have as many grades of power as possible, to include

smooth crescendo as well as sforzando effects

The Ampico mechanism alters the size of the main passage-way (and hence the power) by means of a regulator valve, which is attached to a lever, controlled by a set of pneumatics under vacuum (three small "intensity" pneumatics above, balanced by a large "spring" pneumatic beneath). When marginal perforations connect up to the valves of the "intensity" pneumatics, these lift and allow the pneumatics to fill with air, thus exerting an up-push on the lever, raising the regulator valve and increasing the size of the passage-way. As these pneumatics lie along the lever, their lifting power depends upon position, those furthest from the fulcrum end being the most effective. When it is necessary for an intensity pneumatic to collapse again, another marginal perforation, connecting up to a "cancel" valve, admits air and allows this to happen. Further marginal perforations are provided, one for slow crescendo, and the other for fast crescendo, each connecting up to the same crescendo pneumatic, but in the latter case two ways are open for the air to escape, making the pneumatic collapse quickly. For "brilliant" or extra powerful performance, the Ampico can be switched over so as to close the slight "in-leak" provided on one of the three pumpers of the power mechanism. The whole system then works at maximum power. For subdued performance the main passage-way is blocked by a disk, operated pneumatically from a switch in the spool-box.

The Angelus Arrio system employs thirteen expression openings, all leading from the interior to the exhaust pumps. Five of these are in the controlling governor, and the others in the treble and bass sections. They vary in size from tiny vents to a large "melody" opening, and all air must pass through one or more openings on its way from tracker-bar to main exhaust. In addition, there is an "in-leak" as on the Ampico, but the Angelus system works it from the tracker-bar. When a perforation appears against the second hole from the left-hand side, the "in-leak" is closed and an increase of power results.

The Duo-Art (Aeolian Company) is essentially a theme and accompaniment expression arrangement, the former being at a higher dynamic power than the other. Each has a knife-valve control of the passage-way, operated by a set of four pneumatics, varying in their amount of possible collapse. In this way sixteen variants of power are obtained. There is also an "in-leak," automatically closed by another knife-valve so as to get maximum power when the passage-way is already nearly full open.

The Welte-Mignon is worked by suction fan instead of the usual pumpers. Its expression unit consists of a governor bellows, held open by a coiled spring. This controls the position of a conical valve in the passage-way, and is itself automatically responsive to the amount of work being done at any moment within the pneumatic system. The expression pneumatic, which also works the same conical valve, is operated from the tracker-bar, and can act slowly or quickly according to the perforations in operation.

Value of the Player-piano.—The player-piano in its modern perfected form enjoys the whole-hearted support of musicians. In schools it has proved invaluable, while in musical colleges and academies it is utilized as a means of familiarising students with the interpretations of the greatest performers.

PLAYFAIR, JOHN (1748-1819), Scottish mathematician, was born at Benive, Forfarshire, where his father was parish minister, on March 10, 1748. He was educated at home until the age of 14, when he entered the University of St Andrews. He was ordained, and succeeded his father in the parish of Benive, but continued his scientific studies. In 1785 he succeeded Dugald Stewart in the chair of mathematics at Edinburgh, which he exchanged in 1805 for that of natural philosophy. In 1795 he published his *Elements of Geometry*, which later passed through many editions. He enunciated the axiom now known by his name, viz., that two intersecting straight lines cannot both be parallel to the same straight line. He was elected F.R.S. in 1807. He died in Edinburgh on July 20, 1819.

His other publications include *Illustrations of the Huttonian Theory of the Earth* (1802), *Outlines of Natural Philosophy* (2 vols., 1812-16). His collected works, with a memoir by J. G. Playfair, were published at Edinburgh (4 vols. 1822).

PLAYFAIR, LYON PLAYFAIR, 1ST BARON (1818-1898), was born at Chunar, Bengal province, on May 21, 1818, and educated at St Andrews, Glasgow, Edinburgh, University College, London, and under Liebig at Giessen, where he took his doctor's degree. Playfair translated into English Liebig's *Chemistry of Agriculture*. From 1841-42, he was chemical manager of the Pinthrose print-works at Clitheroe, and in 1843 was elected honorary professor of chemistry to the Royal Institution of Manchester. Soon after he was appointed a member of the Royal Commission on the Health of Towns, a body whose investigations may be said to have laid the foundations of modern sanitation. In 1845 he was appointed professor in the new School of Mines, and chemist to the geological survey, and thenceforward was constantly employed by the public departments in matters of sanitary and chemical inspection. For his services as special commissioner of the 1851 Exhibition, he was made C.B. From 1856 to 1869 he was professor of chemistry at Edinburgh University. In 1868 he was elected to represent the universities of Edinburgh and St Andrews in parliament, and retained his seat till 1885, from which date until 1892 he sat as member for Leeds. In 1875 he was made postmaster-general, and in the following year, after the dissolution of parliament, was made president of a commission to inquire into the working of the civil service. Its report established a completely new system, known as the "Playfair scheme." From 1880, when Gladstone returned to power, till 1883, Playfair acted as chairman of committees. In 1892 he received a peerage, and in 1895 the G.C.B. He died in London, on May 29, 1898, and was buried at St Andrews. He published a volume, *Subjects of Social Welfare*.

A memoir by Sir Wemyss Reid was published in 1899.

PLAYFAIR, SIR NIGEL (1874-1934), actor and theatrical manager, was born in London on July 1, 1874. Educated at Harrow and at University College, Oxford, he acted with the Oxford University Dramatic Society. For some time he practised as a barrister. On July 30, 1902, he made his first appearance as a professional actor at the Garrick theatre, London, in "A Pair of Knickerbockers." He was chiefly associated with the Lyric theatre, Hammersmith, London, the management of which he assumed in 1919. Among his most famous productions at this theatre were John Drinkwater's *Abraham Lincoln* (1910) and the revival of Gay's *Beggar's Opera* (1920) which ran for over three years. He published *The Story of the Lyric Theatre, Hammersmith* (1925), and other works. He was knighted in 1928.

PLAYFORD, JOHN (1623-c. 1686), English musical publisher, was born at Norwich. From 1653 he was clerk to the Temple church, and from his shop in the Inner Temple issued most of the English music of his day. Of his own compositions the chief are numerous psalm tunes, the popular *Introduction to the Skill of Musick* (1654, 10 ed. 1730) and *The Dancing Master* (1650), a collection of airs for the violin used for country dances which constitute an invaluable treasury of English national tunes. See F. Kidson, *British Music Publishers*.

PLAY IN ANIMALS. At the very beginning of any discussion of play in animals one is obligated to emphasize the fact that current understanding of the subject is extremely limited. The factual evidence consists exclusively of descriptions of a wide variety of responses which have arbitrarily been lumped together under the rubric of play. The explanations and interpretations presently available are speculative, deductively derived, and untested. Some of the theories purporting to elucidate the causes and results of play are emotionally appealing but scientifically unsound; others appear plausible and may be valid, but none has been subjected to objective verification.

Characteristics of Play.—The general characteristics of playful behaviour in animals as set forth by most students of the subject can be stated briefly. (a) It is almost universally agreed that in animals, as in men, playful responses carry an emotional element of pleasure. (b) Play is characteristic of the immature animal rather than of the adult. Mature individuals sometimes

play, but it is generally believed that they do so less frequently than juvenile members of their species (c) The majority of authorities concur in the belief that play differs from non-playful activities in having no immediate, utilitarian result which affects the continued existence of the individual (d) The type of play is characteristic of the species Furthermore, the nature and amount of play exhibited by members of a particular species vary according to evolutionary position Play is more frequent, occurs during a greater portion of the life span, and appears in more diversified form in the higher animals than in the lower

It should be borne in mind that these generalizations refer to the commonly accepted characteristics of play They are descriptive rather than analytical, and they cannot be used as explanations or interpretations

Types of Behaviour Regarded as Play.—(a) *General Bodily Activity*.—Young children take delight in racing about a room at top speed, stamping violently upon the floor, shouting loudly in utter abandon Many young animals display similar behaviour Colts, calves, kids, puppies and kittens expend vast amounts of energy in vigorous locomotor activity to no apparent biologically useful end They gallop, run, bound and gambol to the point of apparent exhaustion Many observers regard this behaviour as a form of play It is assumed to constitute an outlet for surplus energy, to bring pleasure to the performer, and to lack any practical purpose

(b) *Youthful Practice of Adult Activities*.—The African lion cub lies in hiding and creeps forth, belly close to the ground, to stalk and leap upon an unsuspecting brother or sister Two puppies wrestle and roll in mock combat, sinking tiny teeth into thick fur and uttering infantile growls Twin lambs face each other with heads lowered and forefeet pawing the earth, charging forward, they meet head on and tumble awkwardly on the grass. The common element in such activities lies in their resemblance to similar behaviour patterns which the animal will display in somewhat different form later in life

There are, however, several significant differences between the behaviour of the young and the adult individual When they appear during infancy, the responses do not terminate in the same result which they will achieve in the adult stage The kitten's chase of a ball or a blowing leaf mirrors the cat's pursuit of a mouse, but in one instance food is obtained and in the other it is not. The puppy's battle with his brother reflects the adult dog's combat with other grown animals, but in the infant's struggle no damage is inflicted The young animal's performance is often imperfect and incomplete, whereas that of the adult is relatively polished and well-integrated. From such observations it has been deduced by Karl Groos and others that this type of play serves to prepare the animal for a more efficient adult life It is thought that incomplete and imperfect instincts are modified, strengthened or suppressed during the practice period of youthful play C Lloyd Morgan has suggested that the play period of infancy permits the practice of vital responses under conditions in which error and incompleteness are not fatal The perfection of essential reactions is thus held to take place before the animal is subjected to the exigencies of an independent existence, wherein the forces of natural selection are constantly operating to weed out inefficiency and the penalty for error may be sudden death

It seems probable that this theory may hold good for the play of certain higher mammals (The chimpanzee, for example, passes through a lengthy period of infancy and childhood during which a number of highly important reactions are exercised and possibly organized into biologically effective form) There is, however, no proof that the generalization may correctly be extended to include all examples of this type of behaviour The kitten's play with small, moving objects may indeed improve its abilities as a mouser, but there is no factual evidence to prove or disprove the assumption. In some cases youthful practice is demonstrably unnecessary It is certain, for example, that the frequent sex play of some animals, such as the immature rat, has no demonstrable effect upon the efficiency of adult mating performance It is important to recognize that the existence of a preparatory function of play can be established only by direct test of each activity in

each species

(c) *Exploration and Experimentation*.—Young animals often peck, scratch, claw, pull and bite at objects in their environment, and such activities are sometimes classified as experimental play The puppy's destructive attentions to a book or pillow are interpreted as play which serves to acquaint the animal with the properties and potentialities of the object thus investigated Similarly, certain reactions of the young animal to its companions can be listed under the heading of exploratory or experimental play An eventually practical outcome of such behaviour is held to lie in its tendencies to promote the development of new modes of conduct and to inhibit biologically dangerous reactions Although this assumed function of exploratory play is based chiefly upon *a priori* reasoning, there are some instances in which it can be shown to exist. Wolfgang Kohler reports that captive chimpanzees given stout sticks or poles soon devised a crude form of vaulting or jumping, using the pole as a sort of crutch Originally this response was apparently indulged in as a form of amusement, and was not used as a means of achieving any secondary objective Although further test and observation would be necessary to establish the point, it seems probable that the pole-vaulting response was a form of play, and the outgrowth of experimentation with the stick Later, however, when the apes were confronted with the problem of obtaining a banana which was suspended above their reach they quickly turned the vaulting technique to good use, employing it as a means of getting the fruit

(d) *Social Play*.—Young British warblers are described as engaging in "tilting matches," during which each bird commands a perch and attempts to dislodge other individuals from theirs African lion cubs play "king of the mountain" When one assumes possession of a high spot of ground or climbs on top of some low object, all others try to force him off and take his place "Follow the leader" games occur in the repertoire of several mammalian species Otters have been observed sliding down muddy banks into the water, one after the other in quick succession, and then climbing out to repeat the performance time and again Young monkeys in the jungle often swing single file through the branches, each copying roughly the actions of the animal ahead of him

The group play of chimpanzees is highly diversified, and often resembles certain human activities Kohler's description of "dancing" is illustrative Several apes start to march in single file around a box or post Gradually their pace quickens, and they trot, often with emphasis upon one foot so that a primitive kind of rhythm emerges; and as they trot and stamp the animals wag their heads in time with the rhythm Other kinds of social play occur in this species, and O L Tinklepaugh has suggested that this type of behaviour early in life enhances the individual's adaptability and co-operativeness, both of which are essential characteristics of the chimpanzee

(e) *Play Between Species*.—Although young animals of one species may investigate those of a foreign species, they do not often play together Exceptions to this generalization sometimes occur when two domesticated animals are reared together Thus a dog and a goat may engage in mock battles if they have been associated long enough to establish friendly relations, so to speak.

The outstanding type of interspecies play is that which occurs between man and his pets If we are to accept any of the criteria of play which have been accorded common use, it must be agreed that the dog frequently plays with his master The dog may enter into mock chases or battles with a man much as he would with another dog On the other hand he will with equal willingness participate in a learned game such as fetching the ball, or performing tricks without any material reward It is significant that the animal may initiate the play and in many different ways signalize his desire to stimulate playful relations with the human partner

Explanations of Play.—Several theories have been formulated in an attempt to elucidate the causes of playful behaviour None is completely satisfactory although several are partially serviceable

(a) The *surplus energy theory* holds that play is a safety valve,

providing an outlet for unused vigour. This interpretation has little to recommend it. Energy is not stored up in the organism like water in a reservoir. Animals are either completely rested and ready to react quickly to stimuli from the environment, or they are tired and sluggish in their responses. All types of behaviour occur more promptly and persist longer in the rested individual. The energy expended in play differs in no way from that used in nonplayful pursuits.

(b) A second attempt to explain play is found in the *joy-de-œuvre* theory which interprets play as the expression of a general exuberance, an overflowing enthusiasm for life itself. A serious objection to explanations of this type is that they add nothing to our basic understanding of natural phenomena, in actuality they explain nothing. They involve merely the substitution of one word or phrase for another, although the meaning or significance of the new term is no more precise nor illuminating than the old.

(c) The *instinctive* theory of play in animals was championed by Karl Groos, who interpreted all play as responses based upon inherited tendencies or predispositions. However, to label an act as "instinctive" is not to explain it, and although the form which play takes in various animal species is unquestionably influenced by hereditary constitution, the serious student of behaviour is still faced with the responsibility for determining the stimuli which evoke playful responses, identifying the physiological and psychological processes which mediate the behaviour, and describing in objective terms the eventual effects and results.

(d) *Future Theories*—Although no completely satisfactory explanation for the occurrence of play in animals is yet available, it is possible to predict with reasonable certainty the form which such a theory must assume. In the first place it is obvious that no single hypothesis can be formulated to explain all forms of play in every animal species. The types of activity which have been labelled "play" are so variable in form and complexity that a different interpretation is indicated for each major category. Secondly, it must be recognized that playful behaviour differs from nonplayful pursuits in subtle and often elusive fashion. There is no sharp border line between play and work for animals, or for man. The two types of activity merge insensibly one into the other, and some complex responses may be partly play and partly work. Therefore, any acceptable definition of play must be based upon a list of predominating characteristics which combine to set it off from nonplayful behaviour, and can not be derived from adherence to a single, rigid criterion such as non-utilitarianism, or imperfect, juvenile performance. It is, for example, permissible to state that playful reactions as a class tend to lack the immediate, biologically practical results which normally accompany nonplayful responses, but one can not set up as an inflexible rule the dictum that no activity is play if it achieves a useful end.

Thirdly, play must be explained in purely objective terms. A small start in this direction has been made by workers such as J. B. Cooper, who suggests that the playful execution of certain behaviour patterns is characterized by the absence of the consummatory phase, and by the rapid shift from one element of the pattern to another. Cooper has noted that the play of lions is more prevalent on cool days, and tends to occur most frequently following a major change in the environmental situation (such as release of the animals from an indoor cage, the introduction of new lions into the pride, or the sudden appearance of the keeper). Much more extended analysis along lines such as these will provide the basis for an interpretation of play which is biologically significant and subject to direct test and verification.

It may be pointed out that the play of humans is no more clearly understood than is that of lower forms; and the careful study of animal play offers potentially important results in the increased understanding of similar behaviour in man.

PLEBISCITE, a term borrowed from the French for a vote of all the electors in a country or given area taken on some specific question. The most familiar example for the use of the plebiscite in French history was in 1852, when the coup d'état of 1851 was confirmed and the title of emperor was given to Napoleon III. Its essential characteristic, as distinguished from the referendum (*q.v.*), is this: a plebiscitary vote decides a specific question, *ad hoc* and *pro hac vice*. It is not, as in the case of the referendum, a normal method or procedure of voting applied on a general system to certain classes of legislation. It is sometimes used in England to decide questions of municipal rates or other local questions, and extensively in the dominions and the United States on certain local or state questions. In Europe its use has been almost wholly political and national.

In that sense it is a method of ascertaining the general desire of the inhabitants of a given territory or area. As a means of settling the destination of populations and territories, this method was first used in the French Revolution to defend the wholesale annexations of territory made by the conquering French republic, and subsequently by Napoleon I. It was revived by Napoleon III and applied (successfully for him) in the case of Nice and Savoy, and (successfully for Victor Emmanuel) in the duchies of north Italy during the years 1859–60. The peace conference of 1919 proposed the taking of 17 plebiscites to settle difficult national questions, of which 8 were actually held. Of these the Turkish plebiscite in Transcaucasia was a farce. Others, which decided the fate of Allenstein Marienwerder, of the Burgenland, of Klagenufer, the economic destiny of Luxembourg, the attribution of the northern and southern zones of Silesia, and the partition of Upper Silesia, had substantial and important results, which are noted elsewhere under the individual articles.

The Versailles treaty provided for a plebiscite of the Saar district in 1935 to decide the future of the region.

PLEBISCITARIUS—H. W. V. Temperley, ed. *A History of the Peace Conference of Paris (1919)*, references in Subject Index to vol. vi, 793. *Plebiscites* in Historical Section of Foreign Office Peace Handbooks, Sarah Wambaugh, *A Monograph on Plebiscites*, Carnegie Endowment for International Peace (1920), and *La Pratique des Plebiscites*, Recueil des Cours de l'Académie de Droit International, F. Llewellyn Jones, *Plebiscites*, Grotius Society Transactions (1927).

PLEBS, the "multitude," or unprivileged class, in the early Roman state (from the root *pleo*, seen in Latin *plenus*, fill; cf. Gr. *πληθος*). For the origin and history of this order see **PATRICIANS**. Its disqualifications were originally based on descent, but after the political equalization of the two orders these ceased.

PLECOPTERA (Gr. *πλέκος* plaited, and *πτερόν* wing) is the order of insects known as stoneflies; by some authors it is termed *Perlaria*. It is one of the few orders in which the immature stages are aquatic. They are restricted to unpolluted streams and wave-washed, rocky lake margins. The female lays several thousand eggs, discharging them in masses into the water. The nymphs are active and elongate, have long antennae and a pair of long "tails." The larger forms have gills for respiration, others respire through the integument. Most of them feed on microorganisms and in decaying organic matter, but some groups are predaceous on other aquatic insects and the like. The nymphs may be found in clumps of rotted leaves, masses of debris, or beneath submerged logs and stones, whence the name "stoneflies." When mature, the full grown nymph crawls out of the water and

Left, adult, length about 0.8 in.; Right, nymph, length about 0.6 in.

attaches itself firmly by its leg claws to a rock or other support in preparation for its last moult. The nymphal skin is then burst along the back and the adult emerges, leaving the empty nymphal skin behind.

The adults are soft bodied and range in size from $\frac{1}{4}$ to $\frac{1}{2}$ in length. They have long, many-segmented antennae, a pair of "tails" (minute in some forms), and usually two pairs of membranous wings folded flat over the back. A few species have only one pair of wings, and in a few others the wings are mere stubs or entirely aborted. Most of the species are black or sombre-hued, some are leaf green, and others may be marked with yellow, orange or red. The stoneflies are relatively slow fliers but active runners. They are usually found on stones, foliage or tree trunks along the edge of the stream, or hiding in crevices in bridges or bark. Different groups are diurnal, crepuscular, or nocturnal, the latter are attracted to lights. Adult emergence begins in early winter and continues through summer. The adults have weak, biting mouth parts, and feed on algae, pollen and bud exudates. All forms are important elements in stream ecology and are important as fish food. Both adults and nymphs should be collected in 80% ethyl alcohol.

The order contains about 800 species comprising 14 families. The largest fauna is that of the holartic region; there are about 250 species in North America and over 30 in the British Isles. The Australian and neotropical regions have an extensive fauna, including many primitive forms. A few fossils are known from the Upper Jurassic in Europe and the Lower Permian of Kansas.

PLECTRUM, a small contrivance, made of metal, wood or some other suitable material, and used as a substitute for the finger in plucking the strings of musical instruments. In ancient times the strings of the lyre were sometimes so plucked, while later the lute was similarly played, as are the mandolin and zither to-day, the same term being applied also to the quills and bristles of the harpsichord and spinet.

PLEDGE or PAWN, in law, a "bailment of goods by a debtor to his creditor to be kept till the debt is discharged" (Jones on *Bailments*). The term is also used to denote the property which constitutes the security. Pledge is the *pignus* of Roman law from which most of the modern law on the subject is derived. It differs from hypothecation and from the more usual kind of mortgage in being confined to personal property, and also in that the pledge is in the possession of the pledgee. A mortgage of personal property, in the majority of instances, takes the name and form of a bill of sale (*q.v.*). In the case of a pledge, it is held that a special property passes to the pledgee, sufficient to enable him to maintain an action against a wrongdoer, but the general property, *se*, the property subject to the pledge, remains in the pledgor. As the pledge is for the benefit of both parties, the pledgee is bound to exercise only ordinary care over the pledge. He must, however, insure against loss by fire (35/36 Vict. ch. 93, s. 36). The pledgee has the right of selling the pledge if the pledgor makes default in payment at the stipulated time.

The law of Scotland as to pledge generally agrees with that of England, as does also that of the United States. The main difference is that in Scotland and in Louisiana a pledge cannot be sold unless with judicial authority. Chattel mortgages, which differ from pledges in that the owner retains possession of the article, are uniformly required to be recorded in order to be valid against third parties, but except for a few States and aside from the Factors acts, a pledge, for the validity of which possession must be transferred to the pledgee, will be enforceable against third parties without being recorded. (See also **FACTORS and PAWN-BROKING**.)

PLEHVE, VIATCHESLAF KONSTANTINOVICH (1846-1904), Russian statesman, was born of Lithuanian stock

in 1846. He was educated at Warsaw and at the university of St. Petersburg (Leningrad) before he entered the department of justice, in which he rose rapidly to be assistant solicitor-general in Warsaw, then solicitor-general in St. Petersburg, and in 1881 director of the state police. As assistant to the minister of the interior he attracted the attention of Alexander III by the skill he showed in investigating the circumstances of the assassination of Alexander II. He received the title of secretary of state in 1894, became a member of the council of the empire, and in 1902 succeeded Spaguine as minister of the interior. Plehve carried out the "russification" of the alien provinces within the Russian Empire, and earned bitter hatred in Poland, in Lithuania and especially in Finland. He despoiled the Armenian Church, and oppressed the Armenians of the Caucasus. He certainly did nothing to discourage pogroms against the Jews, and he was credited with being accessory to the Kishinev massacres. His logical mind and determined support of the autocratic principle gained the tsar's entire confidence. He opposed commercial development on ordinary European lines on the ground that it involved the existence both of a dangerous proletariat and of a prosperous middle class equally inimical to autocracy. He was a determined and successful opponent of Witte's policy. An attempt was made on his life early in 1904, and he was assassinated on July 28 of the same year by a bomb thrown under his carriage as he was on his way to Peterhof to make his report to the tsar, the assassin, Sazonov, was a member of the socialist revolutionary party.

PLEIAD, in Greek literature, the name given (by analogy from **PLEIADES**) by the Alexandrian critics to seven tragic poets who flourished during the reign of Ptolemy Philadelphus (285-247 B.C.). In French literature, in addition to the Pleiad of Charlemagne, there were two famous groups of the kind. The first, during the reign of Henri III (1574-89), the chief member of which was Pierre de Ronsard, sought to improve the French language and literature by enthusiastic imitation of the classics, the second, under Louis XIII (1610-43), consisted of authors who excelled in the composition of Latin verse.

PLEIADES, the constellation so called is in mythology the seven daughters of Atlas and Pleione, and sisters of the Hyades. Owing to their grief at the death of their sisters or at the sufferings of their father, they were changed into stars. In another account, the Pleiades and their mother met the amorous hunter Orion (*q.v.*) in Boeotia, for five years he pursued them through the woods, until Zeus translated them all—Pleione and her daughters, Orion and his dog—to the sky. This is one of the few myths really astronomical in origin, for it is based on the relative positions of the constellations in the sky. The names of the sisters are Alcyone, Asterope, Electra, Kelaine, Maia, Merope, and Taygete (Hesiod fr. 275 Rzsch), one is always dim or invisible, because she is Electra mourning for Troy, or Merope, who is ashamed of having wedded a mortal, Sisyphus. All the Pleiades became the ancestresses of divine or heroic families. The early winter rising and spring setting of the Pleiades (Lat. *Vergiliae*) are important dates to the farmer.

See H. J. Rose, *Handbook of Greek Mythology* (1928).

The stars are situated in the constellation Taurus. They are supposed to be referred to in the Old Testament (Job ix 9 xxxvii, 31). The brightest star is Alcyone (η Tauri), of the 3rd magnitude. This group is physically connected, being distinguished from the background stars by community of proper motion. Photographs show a faint nebulosity filling the whole region, there is little doubt that this is rarefied matter made luminous by stimulation of the radiation of the hot stars comprised in it. The distance of the Pleiades is estimated at 100 parsecs (300 light-years), but is not very certainly known.

Alcyone and the other bright stars are of the hottest type of spectrum (Type B), and give out several hundred times as much light as the sun.

PLEISTOCENE (Gr. $\pi\lambda\epsilon\iota\sigma\tau\omicron\nu\varsigma$, most, and $\kappa\alpha\iota\nu\omicron\varsigma$, recent), in geology the epoch which succeeded the Pliocene. The Pliocene is now usually considered the last of the Tertiary period and hence the Pleistocene forms the lower subdivision of the Quaternary era. The period saw the arrival of the great Ice age (see **GLACIAL**

(EPOCH) and the Pleistocene and Glacial period are sometimes used as if synonymous. The general geology of the period is considered under QUATERNARY.

PLEKHANOV, GEORGY VALENTINOVITCH (N BELTMAN) (1857-1918), the founder and for many years the chief exponent of Russian philosophic Marxism, was born on Nov. 26, 1857, in the province of Tambov, of an old noble family. His father wished him to enter the army, but while a student he joined the Narodist (populist) revolutionary movement. In 1876 he led the first great popular demonstration at St. Petersburg (Leningrad) in the Kazansky square. When the majority section of the Narodists adopted terrorist methods in 1879, Plekhanov seceded, and with Deutsch, Axelrod, Vera Sassulitch and Ignatov, formed the Marxist "Liberation of Labour" group in Geneva (1883). He spent 40 years in exile, chiefly at Geneva, from which town he became the intellectual leader of the Russian Social-Democratic movement, in particular playing a

concessions compatible with the maintenance throughout the whole monarchy of the position due to the German Austrians. He sought to compromise the quarrel between Germans and Czechs, and the so-called "points" of 1890, a summary of the bases for a German-Czech understanding, were essentially his work. In the Windischgratz Coalition Ministry (1893-5), Plener took over the portfolio of Finance. Soon after his retirement from the Finance Ministry, Plener was appointed president of the Supreme Audit Department (*Oberster Rechnungshof*). He entered the Upper House in 1900, and died on May 1, 1923.

Plener wrote a series of economic and political works, among others *Die englische Fabrikgesetzgebung* (1871), *Englische Baugenossenschaften* (1873). He published *Erinnerungen*, 3 vol. (1911-21).

PLESIOSAURUS, technically the name of a genus of extinct reptiles of the group Saurapterygia, it is commonly used to apply to all the later members of that group. The typical plesiosaurs are completely adapted for a marine existence in the open sea.

large part in Lenin's early mental development. In the '90s and the early years of the 20th century the two men were closely associated. In Dec. 1900 was founded the SD journal *Iskra* (The Spark) of which Plekhanov was joint editor with Lenin, Martov, and others. In the first split of the Russian SD Party in 1903 Plekhanov was largely on the side of the Bolsheviks, holding views closely akin to those of Lenin.

After the resignation of the Mensheviks from editorship of the *Iskra* Plekhanov and Lenin were joint editors, but some months later differences arose between them on the question of collaboration with the Mensheviks, and Lenin resigned. Thenceforth for several years Plekhanov worked with the Menshevik section of the party, but after 1907, while remaining a Menshevik, he took up an attitude on many issues, particularly on the question of participation in the State Duma and also on illegal activities, in agreement with that of the Bolsheviks. At the end of 1910 he again co-operated with the latter in contributing to the Bolshevik *Zvezda* (The Star) but the alliance did not last long, and when the war broke out in 1914 Plekhanov was foremost in advocacy of the principle of "revolutionary defence" of the country against the Bolshevik policy of working for the defeat of the Government. After the March revolution he returned to Russia and was invited to join the Provisional Government. He refused, but actively supported the Government against the Bolsheviks, and remained an opponent of the Bolshevik revolution until his death in Finland on May 30, 1918.

Plekhanov had an enormous influence on the development of the Socialist movement in Russia. The Moscow Marx-Engels Institute has published a complete edition of his works in 26 volumes. His biggest work is available in German, *Beiträge zur Geschichte des Materialismus*.

PLENER, ERNST, FREIHERR VON (1841-1923), Austrian politician, was born on Oct. 13, 1841, at Cheb in Bohemia, the son of the Austrian statesman Ignaz von Plener (1810-1908). From 1888 onwards he was the acknowledged head of the German Liberals in their struggles against the Slav-Conservative majority in the Chamber. Consequently he represented Germanism on the nationalities question, but was not averse to

They first appear in the Rhaetic and are last seen in the Upper Cretaceous.

A typical plesiosaur has a small head with a large mouth and slender pointed teeth adapted to the catching of fish. The neck is long, often four times as long as the head. The body is relatively short, as is the tail. All four limbs are converted into paddles, no external trace of the fingers being visible.

From these forms two main evolutionary lines appeared. In one, the animals adopted the habit of living on large prey which they captured by their superior speed; in this line the head grew bigger and the neck shorter until it became no longer than the head. The body is comparatively long, the tail little more than the pointed hinder extremity of the body. The paddles become very large indeed, the hinder pair being bigger than the front ones. There are large members of this line in the European Jurassic, with skulls 5 or 6 ft. long and a body length of 16 ft. or more. The giant of the tribe was *Kronosaurus* of the Cretaceous of Australia, with dimensions nearly twice as great.

The other line consists of animals which fed on small quick-moving prey which they seem to have captured by sudden lateral movements of the head and neck. Its most recent member, *Elasmosaurus*, is found in the Upper Cretaceous of Kansas, England, Queensland and New Zealand. In it the head is about 18 in. in length, the neck with as many as 76 vertebrae may reach a length of 19 ft., and the total length of the animal about 30 ft. The paddles of such an animal were about 3 ft. in length. Some plesiosaurs had the habit of eating pebbles which were kept in the stomach to assist in grinding up food. Although the majority of plesiosaurs were marine, some few are always found in estuaries or fresh-water deposits. See REPTILES. (D. M. S. W.; X.)

PLEURISY or **PLEURITIS**. Strictly speaking, "pleurisy" is a medical term which refers to inflammation of the pleura with or without accumulation of fluid in the pleural cavity, but it is customary to include in the definition certain types of pleurisy with effusion of fluid which are not inflammatory in origin. The pleura is a particularly vulnerable tissue and may be involved in disease processes via the blood stream from either the greater or lesser circulation, via the lymphatics, or by direct extension from the

lung, mediastinum, or chest wall.

Dry Pleurisy or Acute Fibrinous Pleuritis.—This may be associated with almost any type of major disease affecting the lung and commonly accompanies the acute pneumonias. The pleura becomes congested and loses its normal glistening appearance, and deposits of fibrin produce roughening of the pleural surfaces. The inflammatory process may subside or may be followed by an outpouring of fluid, producing pleurisy with effusion. Pain localized to the area of pleural involvement is typical of dry pleurisy and is aggravated by coughing or taking a deep breath. Severe pain disappears if the pleural surfaces are separated by the accumulation of fluid.

Wet Pleurisy or Pleurisy with Effusion.—The type of fluid which accumulates in the pleural cavity is determined by the primary disease process producing the effusion. Fluid containing little protein and few blood cells is termed a transudate (hydrothorax), and is not inflammatory in origin. The commonest cause of hydrothorax is heart failure, but pleural transudates may accumulate as the result of a reduced level of plasma proteins or from obstruction to venous and lymphatic channels by tumours. Pleural fluids with higher protein content and more cells are called serous or serofibrinous effusions, and occur in a variety of diseases including tuberculosis, pulmonary infarction, cancer and rheumatic fever. If a pleural effusion becomes grossly purulent, it is termed an empyema.

A pleural effusion is commonly the first sign of pulmonary tuberculosis. The fluid is reabsorbed spontaneously, and the small subpleural tubercle which produced the effusion may not be visible in X-rays following the resolution of the effusion. Tuberculosis initiated clinically by pleuritis is likely to flare up during the subsequent five years if untreated.

A large number of serous pleural effusions remain undiagnosed even after extensive study, and are termed primary or idiopathic effusions. Since early tuberculosis is such a common cause of serous effusion (it is estimated that 40%–60% are tuberculous), it must be assumed that all effusions of unknown cause are tuberculous unless proved otherwise. This means that a patient with a primary pleural effusion should be treated as though he had minimal pulmonary tuberculosis, and should have follow-up chest X-ray examinations for five years. Pleural effusion may be the first sign of cancer of the lung, although it is a late sign and signifies that the cancer is probably inoperable.

Pleuritic Residuals.—Pleuritis usually produces scarring, and the pleural space may be partially or completely obliterated by adhesions. If pleural scarring is extensive the efficiency of the underlying lung as an organ of ventilation is reduced.

Treatment.—Most important is treatment of the underlying disease which produced the effusion. Treatment of the pleurisy is symptomatic. In dry pleurisy the chest may be strapped and analgesics used for the relief of pain. In wet pleurisy fluid may be removed to relieve respiratory distress.

BIBLIOGRAPHY.—E. H. Rubin, *Diseases of the Chest*, p. 546, with bibl (1947); R. L. Cecil and R. F. Loeb (eds.), *Textbook of Medicine*, p. 881, with bibl (1951). (R. H. E.)

PLEURONECTIDAE, the family of fishes to which the name "flat fish" is popularly applied. It includes the flounder and plaice (q.v.). (See FISHES.)

PLEUROPNEUMONIA (LUNG PLAGUE). A specific contagious disease of bovine animals usually terminating in a characteristic inflammation of the lungs and pleura (lining of the chest cavity), pleuropneumonia is caused by a minute, many-shaped organism so small that it will pass through bacteriological filters. By magnifying at least 1,500 diameters, the organism can be seen as small dots or coccoid bodies, spiral forms, branching and star-shaped figures, from which the name *Asterococcus mycoides* was given to the organism by Pierre Borrel. Although extremely small, it probably should not be classed as a truly ultramicroscopic virus.

In earlier times the disease was prevalent over much of Europe, having been recognized by Claude Bourgelat in 1769 in France and known even earlier in Switzerland and Germany. It spread rapidly because of the traffic in breeding cattle, especially from Holland and Switzerland, and caused such great losses that energetic steps of eradication had to be developed, including slaughter of diseased animals, quarantine and veterinary sanita-

tion measures. It is reported that in Great Britain alone 187,000 cattle died of the disease in one year, 1860.

In the United States, contagious pleuropneumonia first appeared in Brooklyn in 1843, in New Jersey in 1847, in Massachusetts in 1850 and then spread over most of the important cattle-raising states east of the Mississippi, causing the deaths of thousands of animals, particularly in Illinois.

The presence of the disease was such a serious problem that the federal government finally intervened to set up an eradication program to supplement the efforts of the several states, this was a major factor in the establishment of the U.S. Bureau of Animal Industry. The ultimate eradication of contagious pleuropneumonia in 1892 was the bureau's first great accomplishment, it did not appear afterward in the United States.

The disease was also eradicated or greatly reduced in most countries, but still occurred at mid-20th century in parts of Asia, Africa, Australia and the USSR.

Natural infection usually takes place by contact of diseased animals with susceptible cattle, probably by inhalation of infective material. The incubation period is about two weeks and the symptoms manifested are fever, loss of appetite, dry painful cough, accelerated pulse and respiration and the usual signs of acute pneumonia. Depending on the extent and severity of the infection, the disease may terminate fatally in a few days or run a more chronic course with apparent recovery. However, the disease may become active again because of foci remaining in the affected lung tissues and death often follows.

No effective treatment had been discovered by mid-20th century, although immunization methods had had some success. Materials used for vaccination by inoculation in the tip of the tail include pleural exudate from naturally occurring cases and culture preparations made from the causative organism. However, neither is entirely satisfactory because a small percentage of vaccines may die and many more lose their tails. The only effective method of dealing with the disease is by eradication, quarantine and other veterinary sanitation measures. Institution of such measures is preceded by a veterinarian's diagnosis through use of the complement-fixation test. A simple slide flocculation test also has been used with success by British workers, particularly in areas where it is not practical to employ the complement-fixation technique.

A sidelight of possible public health interest is the recently expressed view of University of Pennsylvania physicians that bovine pleuropneumonia-like organisms may be responsible for some of the obscure human illnesses of respiratory origin seen in the United States. (J. G. H.H.)

PLEVNA (Bulgarian *Pleven*), a city in Bulgaria, on the Tutchnitza, and Sofia-Varna railway (opened in 1899). Pop (1946) 38,997. A branch line, 25 mi long, connects Plevna with Samovit on the Danube, where a port has been formed. After the events of 1877, it was almost entirely forsaken by the Turks, and most of the mosques have gone to ruin, but, peopled now mainly by Bulgarians, it has quite recovered its prosperity, and has a large commerce in cattle and wine (see RUSSO-TURKISH WARS).

Plevna, a small and unknown town without fortifications, became celebrated as the scene of Osman Pasha's exploits. He left Widin on July 13 with a column consisting of some 12,000 men and 54 guns. Hearing that he was too late to relieve Nikopol, he pushed on to Plevna, where there was a small garrison, and on July 19 he took up a position on the bare hills to the north and east. He was none too soon. General Schilder-Schuldner, commanding the 5th division of the 6th corps, which had just captured Nikopol, had been ordered to occupy Plevna, and his guns were already in action. On July 20, having made no preliminary reconnaissance, the Russian commander advanced his infantry in four separate columns. On the north flank they pressed into Bukova, and also succeeded in driving back the Turkish right wing, but in both cases Turkish counterattacks pressed back the Russians, with the result that by noon they were in full retreat, having lost 2,800 men out of a total of 8,000. The Turks lost 2,000. Osman at once drew up plans for the fortification of the position, and the

troops were employed night and day constructing redoubts and entrenchments. In order to secure his line of communications, he occupied Lovcha (Lovatza). The Plevna garrison had now been reinforced to 20,000. Trenches were 4 ft deep and the redoubts had a command of 10 to 16 ft, with parapets about 14 ft thick. There were in some cases two lines of trench to the front, thus giving three tiers of fire.

Second Battle of Plevna.—In accordance with orders from the Russian headquarters at Tirnova, a fresh attack was made by

MAP OF PLEVNA SHOWING TURKISH ENTRENCHMENTS DURING THE FIVE-MONTHS DEFENCE OF THE TOWN BY OSMAN PASHA AGAINST THE RUSSIANS IN 1877

Kruderer on July 30. He had been reinforced and his force numbered nearly 40,000 with 176 guns. After a preliminary cannonade the infantry advanced at 3 P.M., as before in widely spread columns. The columns attacking from the north and north-east were repulsed with heavy loss. Shakhovskoi temporarily occupied two redoubts, but a counter-stroke by the Turkish reserves forced him back. The Russians retreated, their losses amounting to 7,300, while the Turkish losses exceeded 2,000. The victory was decisive, but Osman again failed to pursue. His troops were elated by success, the moral of the enemy severely shaken, the undefended Russian bridge over the Danube was within 40 m. of him, but he lost his opportunity, and contented himself with strengthening his defensive works. It is said that he was tied down to Plevna by orders from Constantinople.

The Russians now concentrated all their available forces against Plevna and called in the aid of the Rumanians. By the end of August they had assembled a force of 74,000 infantry, 10,000 cavalry and 440 guns. On August 30 Osman moved out of Plevna, and on the 31st attacked the Russians about Pelishat. He returned to Plevna the same evening. The Turks lost 1,300 and the Russians 1,000 men. The Russians determined to occupy Lovcha, and so cut Osman's communications before again attacking Plevna. After three days' fighting this was accomplished by Skobelev, acting under Imzerinski, with a force of 20,000 men, on September 3. Osman moved out to the relief of the garrison that day with a strong column, but, finding he was too late, returned to Plevna on the 6th. The survivors from Lovcha were re-formed into 3 battalions, including which Osman had been reinforced to a strength of over 30,000, with 72 guns.

Third Battle of Plevna.—The Russians moved to their preliminary positions on the night of September 6-7. Their plan was to attack the north-east, south-east and south fronts simultaneously. An artillery bombardment began at 6 A.M. on September 7, and was carried on till 3 P.M. on the 11th, when the infantry advanced. The Rumanians took one Grivitzia redoubt, Skobelev occupied two redoubts on the south front, but the centre attack on the Radischevo front failed. On the 12th the Turks recaptured the southern redoubts, the Rumanians remained in possession of the Grivitzia redoubt, but the Russian losses already amounted to 18,000 and they withdrew, and entrenched themselves on a line Verbitza-Radischevo, with cavalry on either flank to the Vid. The Turkish losses totalled 5,000, of which only a few hundred were

caused by the artillery fire of the first few days. There was no question of pursuit. The Russians were greatly superior in numbers and the Turks were completely exhausted.

Investment and Fall of Plevna.—This was the last open force attack on Osman's lines. General Tolleben, the defender of Sevastopol, was now entrusted with the conduct of the siege, and he determined to complete the investment, which was accomplished by October 24. Osman's request to retire from Plevna having been refused by Constantinople. Supplies eventually gave out and a sortie on the night of Dec. 9-10 failed, with the result that he and his army capitulated.

Plevna is a striking example of the futility of the purely passive defence, which is doomed to failure however tenaciously carried out. Osman Pasha repelled three Russian attacks and practically held the whole Russian army. It remained for the other Turkish forces in the field to take the offensive and by a vigorous counter-stroke to reap the fruits of his successes. Victories which are not followed up are useless. (J. H. V. C.)

PLEYEL, IGNAZ JOSEPH (1757-1831), Austrian musician, was born at Ruppersthal, near Vienna, on June 1, 1757, the 24th son of a poor village schoolmaster. He studied the pianoforte under Van Hal (known in England as Vanhalla), and in 1772 learned composition from Haydn, who became his dearest friend. He was appointed temporary *maitre de chapelle* at Strasbourg in 1783, receiving a permanent appointment to the office in 1789. In 1791 he paid a successful visit to London. He narrowly escaped the guillotine on returning to Strasbourg, and was only saved by the existence of a cantata which he had written, and in which the inspiration could fairly be claimed to be on the side of liberty, so that he was permitted to remain until 1795, when he migrated to Paris. Here he opened a large music shop, published the first complete edition of Haydn's quartets, and founded, in 1807, the pianoforte manufactory which still bears his name. The latter years of his life were spent in agricultural pursuits. He died on Nov. 14, 1831, in Paris.

PLIEKSANS, JAN (1865-1929), Latvian poet and dramatist, was born on Sept. 12, 1865, at Tadenava in the district of Ilukst, Courland. He adopted the pen name of József Ramis. He was educated at the Riga gymnasium, and from 1884 to 1888 studied law at St. Petersburg (Leningrad). He then practised as a barrister at Mitau, Courland. From 1891 to 1895 he edited in Riga a democratic Latvian paper, *Dienas Lapas* (Daily Paper). He was arrested by the Russian Government on political grounds and remained in exile, first at Pskov and then at Viatska, until 1903. He may be considered the chief exponent of democracy in Latvian poetry. He translated plays from Shakespeare, Goethe and Schiller. His principal historical tragedies are *Uguns un nakts* (*Fire and night*), *Put vejums* (*Blow breeze*) and *Daugava* (*The Duma*). *The Sons of Jacob* has been translated into English, and was produced on May 22, 1925, at the New Scala theatre, London, by the International Theatre Society. For several years he was director of the Latvian National Theatre, and in 1920 became member of the Latvian Saeima (parliament).

PLIMER, ANDREW (c. 1763-1837), English miniature painter, was the son of a clock-maker at Wellington. With his brother Nathaniel (1757-c. 1822) he joined a party of gypsies and wandered about with them, eventually reaching London, where in 1781 he was engaged by Mrs. Cosway as studio boy. Cosway sent him to a friend to learn drawing, and then received him into his own studio. In 1785 he set up for himself in Great Maddox Street. He exhibited many times in the Royal Academy, resided for a while in Exeter and travelled a good deal through England. He died at Brighton in 1837 and was buried at Hove. His miniatures are of great brilliance and are in considerable

demand among collectors. They are to be distinguished by the peculiar wry-treatment of the hair and by the large full expressive eyes which Pliny invariably gave to his female sitters, eyes resembling those of his own wife and daughters. See G. C. Williamson, *Andrew and Nathaniel Plimer* (1903) (G. C. W.)

PLIMSOLL, SAMUEL (1824-1898), British politician and social reformer, was born at Bristol on Feb. 10, 1824. His efforts for reform were directed more especially against "coffinships"—unseaworthy and overloaded vessels, often heavily insured, in which unscrupulous owners risked the lives of their crews. Plimsoll entered parliament as Liberal member for Derby in 1868, and failing to pass a bill dealing with the subject, he published a work entitled *Our Seamen* (1872), which made a great impression throughout the country. On Plimsoll's motion in 1873, a royal commission was appointed, and in 1875 a government bill was introduced, which Plimsoll, though regarding it as inadequate, resolved to accept. On July 22, when Disraeli, announced that the bill would be dropped, Plimsoll lost his self-control, applied the term "villains" to members of the house, and shook his fist in the Speaker's face.

Eventually Plimsoll apologised, but the country shared his view that the bill had been stifled by the pressure of the shipowners, and the popular agitation forced the government to pass a bill, which in the following year was amended into the Merchant Shipping Act. This gave stringent powers of inspection to the Board of Trade. The mark that indicates the limit to which a ship may be loaded is generally known as Plimsoll's mark. Plimsoll was re-elected for Derby at the general election of 1880, but gave up his seat to Sir W. Harcourt, in the belief that the latter, as home secretary, could advance the sailors' interests more effectively than any private member. Later on Plimsoll was estranged from the Liberal leaders by what he regarded as their breach of faith in neglecting the question of shipping reform. He became president of the Sailors' and Firemen's Union, and raised a further agitation about the horrors of the cattle-ships. Later he visited the United States with the object, in which he did good service, of securing the adoption of a less bitter tone towards England in the historical textbooks used in American schools. He died at Folkestone on June 3, 1898.

PLINTH, in architecture, the lowest member of a classic base, also any rectangular block on which a statue or vase is placed. In a pedestal or podium the plinth is the lowest member, and usually consists of a projecting, continuous block above which are the base mouldings. (See ORDER.)

PLINY THE ELDER (GAIUS PLINIUS SECUNDUS) (c. A.D. 23-79), Roman polymath, was born at Novum Comum (Como), in Transpadana Gaul, on which ground he claims Catullus, a native of Verona in the same region, as a fellow countryman (*N.H. praef. 1, Catullum conterraneum meum*). The date of his birth is fixed as A.D. 23 or 24 (*Plin. Epp. III. 5.7*). He must have come to Rome at an early age (*N.H. XXXVII. 81*). He practised for some time as an advocate (*Plin. Epp. III. 5, 7, aliquandiu causas actitasse*). He saw military service in various parts of the world, Germany, Spain, Gaul. Under Vespasian, with whom he was on the most intimate terms (*Plin. Epp. III., 5, 9*), he served as *procurator* in Gallia Narbonensis (A.D. 70) and Hispania Tarraconensis (A.D. 73). At some time—the date is not known—he was in Africa (*N.H. VII. 36* "I myself saw in Africa," etc., *cf. XVII., 41, XXV. 123*). Finally Vespasian appointed him praefect of the Roman fleet at Misenum, in Campania, which Augustus had made one of the principal Roman naval stations (Sueton. *Aug. 49*). He was stationed at Misenum when on Aug. 24, A.D. 79 there occurred the great eruption of Vesuvius which overwhelmed Herculaneum and Pompeii and incidentally cost Pliny his life. The circumstances are vividly told in a letter of the younger Pliny to the historian Tacitus (*Plin. Epp. VI. 16*). Surveying the eruption from a ship, Pliny took refuge with his friend Pompeianus at Stabiae (Castel-

lamare) on the southern shore of the Bay of Naples. There, in order to allay the fears of his friends, he died, as his nephew says "cheerfully, or what was equally splendid, with a pretence of cheerfulness," and then retired to rest. In the middle of the night, when stones and ashes were already falling about the house and the house itself was rocking alarmingly, he was roused by his friends and the party determined to seek safety in the open, binding pillows about their heads as a protection against falling debris. "Now it was day elsewhere," to use his nephew's words, "but there night darker and denser than any night, alleviated a little by numerous torches and lights of various sorts. It was decided to go out upon the shore and see at close quarters whether the sea now offered any prospect of safety, it still continued wild and adverse. There Pliny lay down upon a cast-off linen cloth, and once and again he asked for cold water, which he drank. Then flames and a smell of sulphur announcing the approach of flames, caused the others to take to flight and roused him. Supported by two slaves he got upon his feet, but immediately collapsed, his breathing, I gather, being obstructed by the thickening vapour which closed up his throat—naturally weak and narrow and frequently inflamed. When day returned—the third *cf. Plin. Epp. III. 5* English reckoning the second, *cf. Aug. 26*) after the last day (Aug. 24) that he had seen—his body was found intact and unharmed, covered as he had been dressed. The appearance of the body suggested one sleeping rather than dead."

A list of Pliny's writings is given in a letter by his nephew, (*Plin. Epp. III. 5*) as follows. 1. *De iaculatione equestri* (On throwing the javelin from horse-back), "written while he was serving as commander of a cavalry regiment with equal ability and care." 2. *De vita Pompeii Secundi duo* (Life of Pompeius Secundus, in 2 books), "the discharge, as it were, of a debt due to the memory of a friend who had entertained a singular affection for him." This Pompeius, who is described by Tacitus (*Ann. V. 8*) as a man "of refined character and conspicuous ability" was a tragic poet who had also a military career of some distinction. *cf. Plin. N.H. XIV. 56 3 Bellorum Germaniae viginti* (German Wars, in 20 books), "in which he brought together all the wars waged between us and Germany. He began the work while he was serving in Germany, being admonished by a dream. The ghost of Drusus Nero (stepson of Augustus who died in Germany in 9 B.C.) who, having carried his conquest of Germany to the widest extent, died there, stood by him as he slept and commended to him his memory and entreated him to vindicate him from the injustice of oblivion." This work is cited by Tacitus, *Ann. I. 69*, Sueton. *Calig. 8* and *Vita Plinii*, and was probably used by Tacitus in his *Germania*. 4. *Studiosi tres* (The Student, in 3 books) "in which he instructs and perfects the orator from the cradle up" (*cf. Aul. Gell. IX. 16 Plinius Secundus . . . libros reliquos quos studiosorum inscripsit, Quintil. III. 1.21*). 5. *Dubii sermonis octo* (Dubious Language, in 8 books) "written in the last years of the reign of Nero when slavery had rendered dangerous every study of a free and elevated character," *cf. Plin. N.H. praef. 22*. Fragments of the treatise were edited by Beck, Leipzig 1894. 6. *A fine Aulian Bassi triginta unus* (Continuation of the History of Aulian Bassus, in 31 books). The History of Bassus seems to have ended with the reign of Claudius (*cf. Quintil. X. 1. 103, Tac. Dial. 23, Seneca Epp. 30*), and Pliny continued the story down to his own times. *cf. N.H. praef. 20 7. Historiae Naturalis 37* (Natural History in 37 books). This work alone is extant (for fragments of Pliny's lost works *cf. Historicorum Romanorum Reliquiae*, coll. H. Peter, 2, 109 ff.).

Pliny, the Younger, has given a description of the uncle's studious habits. He would call upon the Emperor Vespasian before daybreak and then after performing his official duties, return home and devote what time remained to study. After a light luncheon, if it were summer and he had leisure, he would lie in the sun while a book was read, annotated and extracts made. He never read a book without making extracts, holding that no book was so bad as not to contain something good. Next he had a cold bath, a snack, and a short siesta, after which, "as if it were another day," he studied till dinner-time. During dinner a book was read and notes made. He rose from the dinner

table in summer before night-fall, in winter within the first hour of night. Thus at Rome, but in vacations no time was exempt from study, save bath-time, nay, even then, he had something read to him or he dictated something, while he dressed. When travelling he was accompanied by a shorthand writer armed with book and notebook and in winter provided with gloves. To procure time for study he generally drove even in Rome and his nephew tells how he was once reproved by him for wasting valuable time in walking. When he died he bequeathed to his nephew 160 volumes of annotated selections (*electorum commentarios*) "written on both sides and in the minutest hand," for which, when he was procurator in Spain (A.D. 73) and when the number of volumes was rather less, he had declined an offer from Larius Lacinus of 400,000 sesterces.

The *Natural History*, which was dedicated to Titus, son of Vespasian and his successor as emperor, and of which the first ten books were probably published in A.D. 77, is, as we have seen, in 37 books. Bk. I has a general preface and contains a table of contents of the other books, to each being appended a list of the authors consulted, the order of enumeration corresponding to the order in which they are utilised. These lists contain the names of 146 Latin and 327 foreign authors. Bk. II is devoted to a mathematico-physical description of the world and deals with the heavenly bodies—sun, moon, planets, fixed stars, various meteorological phenomena; the succession of the seasons, the earth's shape and surface phenomena, seas, rivers, springs, and the like. The subject matter of this book affords Pliny an opportunity, which he readily avails himself, to expound his own philosophic creed, which is a modified Stoicism. His view of nature is pantheistic (*N.H.* II. 1). Bks. III–VI are devoted to geography and ethnography. This is unscientific and uncritical but extremely valuable from the incidental facts which it presents. There is an interesting mention of a map of Armenia (*N.H.* VI. 40).

Books VII–XI are occupied with zoology and are the most generally interesting section. The seventh book deals with man and is occupied less with the normal than with the marvellous and portentous, which the scientific creed of the author and his belief in the infinite power of *ingeniosa natura* enabled him to accept or at least not forthwith to reject. Thus we have tales such as would have charmed the ear of Desdemona—of men whose feet were turned the wrong way, of the Mouthless Men (*Asomi*) who subsisted upon the mere fragrance of flower and fruit, of the Umbrella-foots (*Scapodae*) who used their extensive feet by way of parasol to protect them from the sun; monstrous births; precocity or exceptional development of physical strength or speed, of sight or hearing, of mental powers; of men who were unconsciously long of dying. Incidentally (c. 55) he declares his disbelief in immortality. The eighth book treats of terrestrial animals other than man. Here again, amid much that is interesting in detail, there is an unfortunate absence of scientific arrangement and an excessive proneness to accept the marvellous of which he was so unconscious that he expresses surprise at the credulity of the Greeks (*N.H.* VIII. c. 22 *mirum est quo procedat Graeca credulitas*). Hence side by side with sound science, mostly taken from Aristotle and, so far as concerns Africa, from Iuba, we have a host of imaginary animals—winged horses, unicorns, and the like monstrosities. Book IX deals with aquatic animals and scientifically is the soundest of all the zoological books, which is no doubt due to the fact that his information is mainly derived from the *History of Animals* of Aristotle, who treats of aquatic animals with unusual fullness. The marvellous in this book is chiefly represented by his belief in Nereids and Tritons and the usual stories of the human sympathies of the dolphin. The tenth book treats of birds, commencing, according to Pliny's practice of beginning with the largest, with the ostrich. Such classifications as he makes of birds is of an empirical kind and based on very superficial observations. The first part of the eleventh book is occupied with insects—the bee being treated with some fullness—and the latter part with what may be called comparative anatomy. Books XII–XIX deal, generally speaking, with botany, including forestry and agriculture, the subject of Book XVIII, which

is one of the most interesting in this section. Books XX–XXVII treat of medical botany or the medicines derived from plants. Books XXVIII–XXXII deal with other than botanical *materia medica*, i.e., of medicines derived from the bodies of man and other land animals (XXXII). The remaining books are occupied with what may be described roughly as mineralogy, i.e., with metals and metallic products, the precious metals, gold and silver, being discussed in bk. XXXIII, bronze and bronze statuary in bk. XXXIV, painting in bk. XXXV, stone as used in building and sculpture in bk. XXXVI, gems and precious stones in bk. XXXVII.

The style of the *Natural History* gives an impression at once of affection and of slovenliness which may in some degree be attributable to the condition of the text. On the *Natural History* was based the *Collectanea rerum memorabilium* of Julius Colinus (3rd cent. A.D.) and on Bks. XX–XXXII the *Medicina Plinii*, a compilation of the 4th century.

(A. W. M.)

PLINY THE YOUNGER (GAIUS PLINIUS CAECILIUS SECUNDUS) (A.D. 61 or 62–c. 113), Latin prose author, was born at Novum Comum (Como) in Cisalpine Gaul. The second son of L. Caecilius Cilo and Plinia, sister of the elder Pliny, he bore the name P. Caecilius Secundus until the death of his uncle (A.D. 79), who by his will made him his adopted son, when he assumed the name C. Plinius Caecilius Secundus. He was then in his 18th year (*Epp.* VI. 20 5). Educated in rhetoric under Quintilian (*Epp.* II. 14 9, VI. 6, 3), he made his debut as an advocate at the age of 18 (*Epp.* V. 8, 8).

Pliny was fortunate in having as guardian—doubtless under his father's will (*Epp.* II. 1, 8)—L. Verginius Rufus (A.D. 14–97), who had three times declined to become emperor (in Nero's lifetime, Dio 63, 25, after Nero's death, *Plut. Galb.* 10, Dio 64, 4, after the death of Otho, *Plut. Oth.* 18). He thus commenced his public career under the most favourable auspices. He became a *quaestor* in 89 and in 91 a tribune of the *plebs*, withdrawing during his year of office from practice at the bar (*Epp.* I. 23, vii 16, 2, *Paneg.* 95). In 93 he became *praetor* (*Epp.* III. 11, 2; VII. 11, 4, 16, 2, *Tac. Agric.* 6, 45, *Juv.* x. 35) and during his year of office was one of the counsel for the impeachment of Baebus Massa, procurator of Hispania Baetica (*Epp.* III. 4, VI. 29, VII. 33). In 94 or 95 he was appointed *praefectus aerarii Saturni*. Under Nervus in 98 he became *praefectus aerarii militaris*, commissioner of the public treasury in the temple of Saturn. In September 100 he became consul, holding office for two months. His oration of thanks to Trajan for his nomination (*Epp.* III. 13. 1; 18. 1) is what is called in the mss. *Panegyricus Traiano dictus*. After acting as counsel for the defence of two ex-governors of Bithynia—Julius Bassus and Varenus Rufus—he was himself appointed by Trajan, *circa* 111 A.D., governor of that province. Whether he died in that office is not known, but the probable date of his death is 113, since in the Comum inscription Trajan is mentioned without the titles, conferred in 114, of *Optimus* and *Parthicus*. The inscription referred to was inscribed on a marble slab in the wall of the baths (thermae) presented by Pliny to Comum and commemorated that and other benefactions, including a library. The stone was removed to Milan and broken into six pieces. Four of these were built into a tomb in the church of St. Ambrose, and from the only one of these now known Mommsen, with the aid of other records, restored the inscription.

The extant works of Pliny are the *Panegyric* on Trajan already referred to (*cf.* *Epp.* III. 18), which is of some historical importance, the *Letters* in nine books, and a tenth book comprising his *Correspondence with Trajan*. Mommsen (*Zur Lebensgeschichte des jüngeren Plinius*, in *Hermes* 3, 1868), suggests as

dates. Bk. I, A.D. 97, II, early in 100, III, 101 or 102, IV, early in 105; V, 106; VI, 106 or 107, VII, 107, VIII, 109, IX, perhaps at same time as VIII; and *Correspondence with Trajan*, 111-113. Merrill has modified Mommsen's theory by the suggestion that the *Letters* were published in groups. I-II in 97 or 98, III-VI in 106, VII-IX in 108 or 109.

The interest attaching to letters selected and edited for publication, like those of Pliny, is wholly different from that of such a frank and unguarded correspondence as the letters of Cicero. There is in Pliny always a suggestion of pose, of self-consciousness and self-complicity. But the *Letters* are admirable examples of polished and pointed Latinity, while the range of subject and the quality of the persons to whom some of them are addressed render them of singular interest and attraction. As an example of his manner may be taken the letter (I. 21) which he writes on hearing of the death of the poet Martial, who had some time before retired from Rome to his native Bithynia. "I hear that Valerius Marialis has gone, and I am sorry. He was a man able, acute, and keen—one in whose writing there was wit and pungency, yet not less candour. When he was leaving Rome I provided his travelling expenses, a tribute to friendship, a tribute also to the lines which he wrote about me. It was an old custom to reward with honours or money those who had written the praises of individuals or of cities. In our times, like other fair and excellent things, this also among the first has become obsolete: for since we ceased to do things worthy of praise, praise itself we account foolishness. You ask what are the lines for which I showed my gratitude? I would have referred you to the book itself [Martial, X, 19], were it not that I remember certain of them. He addresses the Muse, bids her seek my house on the Esquiline, approach it reverently.

But beware nor in season unpropitious,
Tiptoe reveller, knock upon the door of
Him who dedicates all his days to Pallas,
While he cons for his hearing of the Hundred
What posterity and the after ages
May compare to the writings of Arpinum
Safer go when the lamps of eve are lighted
Than the hour when the ruddy wine is flowing,
On locks perfume-bedecked the roses glowing—
Then stern Catos themselves might read my verses

Did not he who wrote thus of me deserve that I should both speed him then, as I did, in friendliest fashion, and mourn him now, which I do, as a dear friend departed? For he gave me the best that he had to give and would have given me more had he been able. Yet what greater gift can be given to any man than glory and praise and immortality? But his writings will not be immortal! Perhaps not: but he wrote them as if they would be." Other letters of special interest are VI. 16, one of several addressed to the historian Tacitus which gives a vivid account of the death of the elder Pliny (q.v. for citations from the letter) through the eruption of Vesuvius; VI. 20, also to Tacitus, narrating the experiences of Pliny and his mother; those (I. 18, III. 8, V. 10, IX. 34) written to Suetonius, the biographer of the twelve Caesars; II. 17 which gives a description of Pliny's Laurentine villa; VII. 27 which recounts a couple of ghost stories.

The *Correspondence with Trajan* which consists, apart from the first 15 letters, wholly of letters written during Pliny's governorship of Bithynia, contains much that is of value regarding provincial administration under the empire. But the interest of the modern reader centres chiefly in the two letters (96 and 97) relating to the Christians. In the first Pliny writes to the emperor:

Sure, it is my custom to refer to you all matters about which I am doubtful: for who is better able to direct my hesitation or instruct my ignorance? At trials of Christians I have never been present and I am therefore ignorant of the usual practice in regard to the matter and the limits of punishment or inquiry. I have had also no little difficulty as to whether some distinction of age should be made, or if persons of the most tender age stand on the same footing as the more adult, whether the penitent is to be pardoned or if a person who has once been a Christian shall have no benefit of ceasing to be one. Whether the mere name of Christian, apart from crime, is punishable, or only crime coupled with the name. Meanwhile in the case of those reported to me as

Christians I have followed this procedure. I asked themselves whether they were Christians. If they admitted it, I put the question a second time and a third, with threats of punishment. If they persisted in their confession, I ordered them to be led to execution; for I had no doubt that whatever the nature of that which they confessed, in any case their pertinacity and inflexible obstinacy deserved to be punished. There were others of a similar delusion whom, as they were Roman citizens, I noted for remission to Rome.

Presently the mere handling of the matter produced the usual result of spreading the crime, and more varieties occurred. There was published an anonymous pamphlet containing many names. Those who denied that they were Christians or ever had been, when after me, they invoked the gods and worshipped with incense and wine your statue which I had ordered to be brought for that purpose along with the images of the gods, and, further, reviled Christ—things which it is said that no real Christian will do under any compulsion—I considered should be dismissed. Others who were named by the informer admitted that they were Christians and presently denied it, admitting indeed that they had been, but saying that they had ceased to be, some several years before, some even twenty. All these likewise did homage to your statue and to the images of the gods and reviled Christ. They affirmed moreover that the sum of their crime or error was that they had been wont to meet together on a fixed day before day-break and to repeat among themselves in turn a hymn to Christ as to a god and to bind themselves by an oath (*sacramentum*), not for some wickedness but not to commit theft, not to commit robbery, not to commit adultery, not to break their word, not to deny a deposit when demanded, these things duly done, it had been their custom to disperse and to meet again to take food—of an ordinary and harmless kind. Even this they had ceased to do after my edict by which, in accordance with your instructions, I had forbidden the existence of societies (*convivia*). For these reasons I deemed it all the more necessary to find out the truth by the examination—even with torture—of two maids who were called deaconesses (*ministrae=deacones*). I found nothing but a perverse and extravagant superstition.

I have therefore adjourned the inquiry and have had recourse to consulting you. For the matter seemed to me one deserving a consultation, especially in view of the number of those implicated. For many persons of every age, of every rank, of both sexes even, are daily involved and will be, since not in the cities only, but in villages and country districts as well, has spread the contagion of that superstition—which it seems possible to check and correct. At any rate it is certain that temples which were already almost deserted have begun to be frequented, the customary religious rites, long interrupted, are being restored, and fodder for sacrificial victims—for which hitherto it was rare to find a purchaser—now finds a market. Whence it is easy to infer what a mass of men might be reformed, if penitence were recognized.

The reply of the emperor briefly approves of the procedure adopted by Pliny.

No formula capable of universal application can be laid down. The Christians are not to be sought out; if reported and convicted, they are to be punished, with this reservation that any person who denies that he is a Christian and confirms his testimony by overt act, that is, by worshipping our gods, however suspect he may have been in the past, shall obtain pardon by penitence. Anonymous publications ought to have no place in a criminal charge. It is a thing of the worst example and unworthy of our age (*et pessimi exemplum nec nostri saeculi est*).

The full discussion of the questions raised by the correspondence on the matter of the Christians belongs to the province of Church history, but no one can fail to be interested in the account which Pliny gives of the practice of the early Christians: the meeting on a fixed day before day-break (if the "fixed day" means Sunday, the early hour points to a desire for secrecy perhaps rather than to the rest of the day being occupied with other avocations), the singing or reciting of a hymn or psalm of an antiphonal character (*et OT Psalm lxxxvii. 7*), the recital of the ten commandments, the love feast (*ἀγάπη*) with its innocuous elements; the existence of women office-bearers or deaconesses.

When a person selects for publication from his private letters, or when he writes a private letter with an eye to its eventual publication, he is necessarily confronted by a dilemma. The self-revelation, the candour of motive, the frankness of prejudice or predilection, which are not merely appropriate to the private letters but are its chief charm, are incompatible with the reserve which is proper to a public document, and while suppression and excision inevitably produce an air of unreality, unreserved publication is almost certain to expose the writer to a charge of pugnaciousness or self-conceit. Those who care to attack Pliny on this ground

will find a store of arrows ready-winged for their satire in his letters, even without mistranslating or misunderstanding his words (e.g., "*Maxime instabilis*" used quite innocently of Tacitus in VII, 20)

It is a kinder and more pleasing occupation to recognize the amiability and culture of the character which the *Letters* everywhere reveal and, what at least no competent judge will seek to controvert, the many admirable qualities—consciousness combined with lucidity, precision written with the picturesque—of the style in which they are written.

It need only be added that though Pliny on occasion courted the Muses (Epp. IV, 27, *Ego interduum versus ludo*, cf. Mart. X, 19, *Non Musis vacat ut suis vacare*) and wrote a Greek tragedy at the age of 14 (Epp. VII, 4), the specimens of his verses which he quotes (Epp. VII, 4 and 9) do not suggest that his talent lay in that direction.

PLIOCENE (πλιόκαιος, more, and καιός, recent) is the geological epoch succeeding the Miocene and just preceding the great glacial epoch (Pleistocene) and the rise of man. The name was introduced by Sir Charles Lyell (in 1830, published in 1833) for the youngest of his three divisions of the Tertiary period of time. He placed in the Pliocene the Tertiary beds at Tuscany, those at the sub-Apennine hills in Italy and the beds of English chalk. Because a more nearly complete succession of contemporaneous formations was subsequently discovered in America and elsewhere, the problem of Pliocene boundaries became complex, the correlation table is a tentative summary based on time-tested evidences.

Physical Conditions.—The Pliocene was initiated by wide emergence of land, accompanied by its breaking by orogenies into a more diversified topography and climate than in the Miocene. A connection of North and South America was finally established. North America and Europe continued to be connected in the north throughout the Tertiary and early Pleistocene.

In the old world the emergence was followed by a transgression of the great Mediterranean sea (Tethys) over the lowlands of southern Europe, causing equable climate with an average 18°-21° F. annual temperature. But in the medial Pliocene this sea retreated again, and acquired its present borders and its climate became more heavily continental.

The *Sarmatian* sea, that stretched from the mid-Danubian region to the Aral sea, contracted in Pliocene time and was divided into numerous basins. At the end of Miocene time the northern and southern parts of the Caucasus were united and be-

came the Asiatic peninsula, separated from the southern Russian plain by a strait. Land connection occurred there in Cimmerian time, but at the end of the Pliocene a new transgression connected the Black and Caspian seas; and at the end of Tertiary time they became separated again. Crimea was connected with Anatolia, making the northern peninsula of Pontian (Asia Minor) a land mass, from the early Miocene till the end of Cimmerian time.

In England the London basin was occupied by a large bay of the North sea; but late in Pliocene time the sea became contracted, halting a little longer at parts of East Anglia. In California the sea withdrew at the close of the Miocene but returned again, spreading especially in middle Pliocene. At the close of the Pliocene many basins became isolated and freshened, as the climate gradually grew cooler.

The Pliocene was terminated by widespread withdrawal of the sea because of local ocean floor sinking that accompanied continental uplift and mountain rising. Sufficiently large areas, including ice-covered mountain peaks, had come so close to the snow line that ice spread over them, thus starting Pleistocene glaciation of the earth.

Marine Life.—Molluscs and other invertebrates of the sea were mostly the same as recent, but provincialism is noticeable in some marine faunas such as those of California and the Black sea area. Many aberrant and highly specialized porpoises lived in Pliocene time; but gradually the modernized dolphins, which have changed but little since the end of the Miocene, crowded the ancient rivals from the seas. Modernized types of whales made their appearance at the close of Miocene time; and the specialized *Balaenula balaenopsis*, the precursor of living genera of the family Balaenidae, in middle Pliocene time. The extinct killer whale, *Orcinus citoniensis*, of the dolphin family is known from Asian beds.

Continental Deposits and Life.—Sandy continental deposits of the high plains, called Ogallala, occupy a belt about 200,000 sq. mi. east of the Rocky mountains. In them are buried widespread remains of seeds of *Stipidium* (related to spear grass *Stipa*), *Nassella*, wild millet, many borages, sedges and other herbs. Forests of poplar, willow, hackberry, elm and other trees grew only along the larger valleys.

Abundant remains of grazing mammals indicate also that in this region grassland predominated over the forest. The Miocene forest horse, *Hypophippus*, continued into the Pliocene, but prairie horses became dominant and widespread. Such was *Hipparon* (an important grazer common to America and Eurasia), the advent of which marks the beginning of the Pliocene. Typical are also the grazers *Pliohippus* and *Protolophus*. Other common extinct mammals comprise camels, *Procamelus* and *Paracamelus*, hornless rhinoceros, *Peraceras* and *Aphelops*, and horned *Teleoceras*, the grotesque three-horned *Synthetoceras tricornutus*, beaver *Dipodops*, and many others.

Correlation Chart for Pliocene and the Directly Preceding and Succeeding Geological Epochs

North American		China	Northern India	Southern U.S.S.R.	Rumania, Austria	England	France	Mediterranean		Epochs
Standard continental (high plains)	Marine in California							Continental in western Europe	Standard marine	
Nebraskan glacial stage			Lower boulder beds	Kujahic	Upper Levantin	Red Crag		Guns glacial stage		Early PLEISTOCENE
BLANCAN	Tulete	Nihowan (Sarmatian)						VILLAFRANCHIAN	SICILIAN	
(Kimball) KIMBALLIAN (includes Sidney gravel)	San Joaquin		Puioi	CIMMERIAN (warm Pontian)	Lower Levantin	Coralline Crag	Trevoux Montpelier	Adria-Wilchian Montpelier	ASTIAN	Late Pliocene
(Ash Hollow) "HEMPHILLIAN" (includes Burge channel)	Ethegeon	Ertanis (Dnieper-nor)	Tetrot	PONTIAN (retracted)	Freshened Dnieper (Dnieper beds)	Marine Leinham beds or Dieitian	St. Amant Mollon	Neo-Rhodanic Casino	PLAISANCIAN	Medial Pliocene
(Valentine) "CLARENDONIAN"	Jacallos	Lutseku (Bryghow red clay)	Dhoo Pathan and Nage	MEOTIAN (Lower Pontian)	Meotian (Conger beds)		Mount Libanon	Paleo-Rhodanic Pilekian	MESSINIAN	Early Pliocene
(Sheep Creek)	Delmontian (Upper Monterey)	Tung Gur	Chinji	SARMATIAN				Adia VINDOBONIAN		Late MIOCENE

Note. The recommended terms are capitalized. Fossil names and orogenies (mountain-building processes) are in italics.

Grassland and its inhabitants disappeared from this region in the late Pliocene, when a desert, with swamps and shallow lakes, developed. Next came a gentle eastward tilting of the land that drained it and started its Pleistocene erosion, which is still continued.

In Europe, in early Pliocene time lived *Rhinoceros* and *Acrotherium*, giraffes, *Cameloparadis* and others, *Mastodon* and *Dinotherium*, also the ostrich and other birds. In eastern Asia the "Hipparion fauna" includes tapir and primates, *Macacus* and *Procmoccephalus*, and in India there were more highly specialized primates, proboscidean *Stegodon* and *Archadiskodon*, *Camelus* and others.

Undoubtedly grassland existed not only east of the Rockies but also in other places of the world, and certainly there were some desert floras during the Pliocene. However, forest floras predominated. Along the stream borders in western North America grew *Ulmus*, *Persea*, *Alnus*, *Platanus*, *Populus*, *Salix* and evergreen oak, while giant *Sequoia* grew only close to the Pacific. Next to this vegetation, particularly in the south, grew a chaparral flora made of *Arctostaphylos*, *Ceanothus*, *Cercocarpus*, *Garrya* and *Heteromeles*, while the higher altitudes were covered by *Cupressus*, *Libocedrus*, nut pine, oak and *Robinia*.

The Mediterranean flora was much the same as it is today: *Laurus*, *Persea*, *Fraxinus*, *Populus*, *Quercus*, *Juglans*, *Buxus* and dwarfed palm *Chamaerops*. *Quercus* was the flora of England, which was dominated by Japanese and North American elements, plus some mixture of Himalayan and Indo-Malayan types, but at the end of the Pliocene, west Asiatic and European forms became equally prominent.

PLOCK or **Plotzsk**, a town of Poland in the province of Warszawa, on the Vistula, 67 mi by the Vistula W.N.W. of Warszawa. Pop. (1931) 34,777; (1946) 28,508. It has a cathedral, dating from the 12th century, but restored in 1903, which contains tombs of Polish dukes and of Kings Wladyslaw and Boleslaw (of the 11th and 12th centuries).

There is considerable navigation at this point on the Vistula. German troops took Plock soon after the start of World War II in 1939. It was returned to Poland in 1945.

PLÖRMEL, a town of western France in the department of Morbihan, 36 mi N.N.E. of Vannes by rail. Pop. (1946) 3,871. Plörmel (*Plou Armel*, people of Armel) owes its name to Armel, a hermit who lived in the district in the 6th century. The Renaissance church of St. Armel (16th century) is remarkable for the delicate carving of the north façade and for fine stained glass. It also possesses effigies of John II and John III, dukes of Brittany, brought from their tomb in an ancient Carmelite monastery founded in 1273 and destroyed by the Protestants in 1592 and again in the Revolution.

The lower ecclesiastical seminary has a room in which the Estates of Brittany held several meetings.

PLÖESTI, the capital of the department of Prahova, Rumania; at the southern entrance of a valley among the Carpathian foothills, through which flows the river Prahova, and at the junction of railways to Buzau, Bucharest and the Transylvanian system. Pop. (1948) 95,632. As the name Plöesti (*pluvien*, rainy) implies, the climate is moist. The surrounding hills are rich in petroleum, salt and lignite.

Plöesti is the greatest centre of the Rumanian oil industry, and as such was severely bombed by British, Americans and Russians

in World War II. There are cardboard factories, roperies, tanneries and oil mills. Plöesti possesses schools of commerce and of arts and crafts, several banks, and many churches, including the Orthodox church of St. Mary, built in 1640 by Matthew Basarab.

PLOMBIÈRES, a town of eastern France, in the department of Vosges, on a branch line of the Eastern railway, 17 mi S. of Epinal by road. Pop. (1946) 1,452. The town stands at a height of 1,410 ft. in the picturesque valley of the Aurgonne. It is famous for its mineral springs, containing sodium sulphate and silicic acid, varying from 66° to 166° F. The waters have been used since Roman times.

PLOTINUS (A.D. 204 or 205–270) was a native of Egypt, but it is not known from what race he sprang. As a young man he studied philosophy at Alexandria, and at last found a congenial teacher in Ammonius Saccas, under whom he worked till he was 39. Then he accompanied the expedition of the emperor Gordian against Persia, hoping to have an opportunity of studying the wisdom of the east. Gordian was assassinated in Mesopotamia and Plotinus escaped to Antioch with difficulty. In 244 he went to Rome, where he lived for the rest of his life. There he opened a school and gathered round him an enthusiastic band of disciples.

For many years the instruction was purely oral, and Plotinus took but little pains to perpetuate his teachings. We owe the preservation of it mainly to his pupil Porphyry, who edited his scattered lectures and tried to reduce them to order. The philosopher died after a long illness at the age of 66. His biographer Porphyry described him as a man of saintly character and very attractive personality.

In Plotinus philosophy and personal religion were closely connected, the apex of the dialectical pyramid was also the beatific vision in which the mystical life culminates. He made no enemies and was loved and revered by all who knew him. The later members of the school spoke of him as "the most divine Plotinus."

The importance of Plotinus in the history of thought can hardly be exaggerated. Among the philosophers of mysticism he holds an undisputed pre-eminence, since no other writer enters in the same measure metaphysical genius with intimate personal experience.

On the theoretical side he draws mainly from Plato, but on Plato as interpreted by a long series of scholars, and buttressed by Aristotle and (to a less extent) by the Stoa. The rival schools of Greek philosophy were in fact beginning to coalesce into a theocentric system, at once universal and individual, of religious discipline. Plotinus gave an impetus to this fusion, for the victory of his philosophy was so rapid and overwhelming that it absorbed the other schools, and when Neoplatonism captured the Platonic academy at Athens, the seat of the official Diadochi, it reigned almost without a rival until Justinian closed the Athenian schools in 529.

Neoplatonism remained attached to the classical tradition, and Porphyry wrote against Christianity. But even Augustine recognized that the differences between Platonists and Christians were slight, and the church gradually absorbed Neoplatonism almost entire. The Christian Platonists of Alexandria led the way; then came Augustine himself, the Cappadocian fathers and the Pseudo-Dionysius, a disciple of Proclus, whose writings, popularly ascribed to St. Paul's Athenian convert, introduced the whole scheme of Plotinian mysticism into the church. It is no paradox to say with Eucken that the pagan Plotinus has left a deeper mark upon Christian thought than any other single man. In reading the *Enneads* we can realize the truth of Troeltsch's famous dictum, that the Catholic Church does not belong to the middle ages but is rather the last creative effort of classical antiquity, which may be said to have died in giving birth to it. Troeltsch adds that in a new synthesis of Neoplatonism and Christianity lies "the only possible solution of the religious problem at the present day," and "does not doubt that this synthesis will once more be dominant in modern thought." Such a judgment, from the foremost thinker of his day in Germany, is enough to show that the philosophy of Plotinus, so far from

being extinct, is still a factor in modern civilization. As Eunapius said, "the altars of Plotinus are still warm."

His Philosophy.—Whatever English equivalents we choose for the Plotinian technical terms must be misleading. The "Matter" of Plotinus is immaterial, being the all-but nothing which remains when we have deprived an object of contemplation of the form and meaning which make it a possible object of contemplation. "Soul" is often nearer "life," the word usually translated "intelligence" is much nearer to "spirit." "God" is not the deity of personal theism, and the Absolute is "beyond existence." It is mainly mistranslation of technical terms that has caused many to ascribe metaphysical dualism to Plotinus, for which there is no ground whatever. There are no hard and fast dividing lines in this philosophy, but a graduated hierarchy of existence and value, in every grade of which the soul finds affinities.

The soul is a stranger among the things of sense, into which it has "come down." From the desire of Soul to create after the pattern of Spirit, "the whole world which we know arose and took its shapes." The universal soul is the creator and providence of the visible world, which is in it, rather than the soul being in the world. "There is nothing between soul and spirit except that spirit imparts and soul receives." But even the Matter of Spirit is beautiful and of spiritual form. "There is nothing Yonder that is not also Here." Plotinus therefore blames the half-Christian Gnostics, who despise the visible world and are blind to its beauties. Souls cannot be divided quantitatively, "all souls are one." In the spiritual world there is distinction without separation; individuality is preserved, but all spirits are transparent to each other. Even on earth there is a "faint sympathy" which connects all beings together, a pale reflection of the complete unity in plurality which prevails Yonder. The character of the soul depends on the sphere in which it voluntarily moves. If it chooses to live among the shadows of the true, it forfeits its birthright, and is "lost," so far as a divine being can be lost. There is a higher soul which never consents to sin, and remains in the eternal world. (Here the school was to differ. Later Neoplatonists asked, "If the will sins, how can the soul be impeccable?")

The soul neither comes into existence nor perishes; "nothing that possesses real being can ever perish." But souls that have lived unrighteously will be punished by being reincarnated in the bodies of lower animals; the soul will also be chastened by its daemon or guardian angel. It is not quite clear whether every soul must at last find deliverance from its chains. The world Yonder is the haven of Neoplatonism. It is the realm of spiritual existence, in which the ultimate and eternal values—Truth, Goodness and Beauty—are fully realized and fully operative. It consists in the unity of *Nous*, *Noësis* and *Noëta*, in which the whole nature of the Absolute is manifested. It is essentially a kingdom of values, but of values which are fully realized. It is eternal, not as existing through an infinite series of moments, but as belonging to the divine life, of which indestructibility is an attribute. The world reflects in its everlastingness the eternity of its archetype. There is no change or progress Yonder, since the perfect cannot receive augmentation; but there is unceasing life and movement, which on the lower side is manifested in perpetual creativeness. The lower orders of being proceed from the higher in a constant stream, though the higher loses nothing in the process of creation. The lower is immanent in the higher, not the higher in the lower. Nothing that takes place in time can affect the essential nature of eternity.

The duality in unity of the spiritual world points to an absolute unity behind it. This unity, though the necessary culmination of the dialectic, is beyond knowledge and existence, and is revealed to experience only in the mystical trance. The "soul become spirit" cannot rest even in this state of blessedness; it is impelled by its inner nature to aspire still further, "always attaining and always striving upward." Plotinus is convinced that in the mystical state we have actually an experience of formless intuition. This is, it is needless to say, the testimony of all the mystics, of every age, country and creed. The mystical ascent seems to those who pass through it to be a progressive stripping

off of everything that is alien to the purest nature of the soul, which cannot enter into the Holy of Holies while any trace of earthliness still clings to it. Hence the constant reiteration of such symbols as nakedness, nothingness and darkness. Plotinus in the well-known sentence with which the *Enneads* as arranged by Porphyry end, defines it as "a flight of the alone to the Alone." He gives us several eloquent descriptions of the mystical trance, drawn evidently from intimate personal experience, but like other mystics he knows that it is impossible to utter the ineffable, and repeats cautions like "The vision is for him who will see it," "he who has seen it knows what I say."

It is part of the fundamental sanity of Plotinus that he always speaks of the vision of the One as an exceedingly rare experience. It is the consummation of a life-long quest of the highest, to be earned only by intense contemplation and unceasing self-discipline. He says nothing of supernatural favours granted for their encouragement to young aspirants. Nor are there any traces of those attempts to force the pace which in many mystics produce the terrible reactions which are described as the dark night of the soul. This sense of detachment, which fills so large a place in the records of the mysticism of the cloister, may have some connection with a deeper sense of guilt and sinfulness than the Neoplatonists ever felt, but it is partly the effect of nervous overstrain and of severe mortification of the body, which Plotinism has never encouraged. Plotinus, as we have seen, lived the active and sodable life of a professor among his pupils; his habits were austere simple, but neither he nor his disciples tortured themselves like Heinrich Suso and many other Catholic saints. The combination of healthy asceticism with humanism is the hall-mark of Plotinists in all times.

The ethical scheme of Plotinus falls, like everything else in his philosophy, under three heads—purification, enlightenment and unification. The "political virtues," which include all the conduct expected of a good citizen, are the preliminary but indispensable prelude to the course. It was not to be expected that any writer in the 3rd century of our era should show much interest in what we call social questions, which occupied the attention of Plato and Aristotle. The special task of philosophy in that distracted age was to isolate religion in its purity, detaching it from all that was local and temporal, and bringing to light its innermost essence. To have done this is an achievement of permanent value, and we must not blame Plotinus for his apparent indifference to the misfortunes which were threatening his country. But, like all the ancients, he does not sufficiently emphasize our need of our fellow-men to develop the best in human nature. The bravest of the Greeks could never renounce the hope of making himself invulnerable.

Neoplatonism culminates in Plotinus. Of his successors, Proclus alone was a thinker of the first rank, and in Proclus the system is intellectualized and scholasticized. The later history of this type of religious thought and practice is mainly within Christianity. As a philosophy, it was restated with acumen by Scotus, Erigena and Meister Eckhart; but many of the post-Kantians are deeply indebted to Plotinus, and Troeltsch is probably right in thinking that even in the future Christian philosophy must continue to be largely Plotinian. The Church carried off this Hymettian honey to its hive just at the time when the intellectual formulation of the victorious creed was taking its permanent shape.

(W. R. I.)

BIBLIOGRAPHY.—The *Enneads* of Plotinus were first made known in the Latin translation of Marsilio Ficino (Florence, 1492) which was reprinted at Basle in 1580, with the Greek text of Petrus Perus. Later editions by Creuser and Moser ("Didot" series, 1855), A. Kirchhoff (1856), H. F. Müller (1878-80), R. Volkman (1883-84). There is an English translation of selected portions by Thomas Taylor, re-edited in Bohn's *Philosophical Library* (1895, with introduction and bibliography by G. R. S. Mead). Translation of the whole (except *Ennead* vi, not yet published (in 1928) by S. MacKenna.

On Plotinus generally see article in Suidas; Eunapius, *Vita sophistarum*; and above all the *Vita Plotini* by his pupil Porphyry. Among modern works, see the treatises on the school of Alexandria by J. F. Simon, 1 (1845), and R. Vacherot (1846), A. Richter, *Ueber Leben und Geseinsentwicklung des Plotin* (Halle, 1864-67); T. Whittaker, *The Neoplatonists* (1901); A. Drews, *Plotin und der Untergang der antiken Weltanschauung* (1907); E. Caird, *Evolution of Theology in*

An important species native to China is the plum (*P. salicina*), which was domesticated in Japan and was introduced into the United States about 1870.

Two less important species are the myrobalan plum (*P. cerasifera*), a native of Europe, and the Simon or apricot plum (*P. simoni*), a native of China. The myrobalan plum has been used a great deal in the United States as a rootstock. Varieties of *P. cerasifera* and *P. simoni* are noted for their ornamental foliage.

Botanists have divided the native American plums into a number of species and subspecies.

Many of them have numerous characteristics in common, so that they overlap somewhat in horticultural groups and classifications. *P. americana*, the most important of the native species, has a wide range of adaptation in the United States, extending from Maine to Florida, westward to Utah, and northwestward into Manitoba. The tree is small, not so vigorous as the European, and it has rough, shaggy, grayish bark. The fruit is red, reddish-yellow, or reddish-orange, and possesses a pleasant flavour and is of good quality, but it has a thick, tough skin and the flesh clings to the pit. Desoto and Weaver are among the typical cultivated varieties of *americana*.

Other American species of minor importance from a commercial standpoint but of interest to the fruit breeder are the native varieties of *P. hortulana*, the chickasaw plum (*P. angustifolia*), and the wildgoose plum (*P. missouriensis*) of the southeastern and south central United States, of which Wildgoose and Robinson are important varieties.

Still other species of plums growing in North America are the Canada plum (*P. nigra*), which is adapted to the north central United States and Canada, the small beach plum (*P. maritima*), which grows along the eastern seacoast, and the western or Pacific plum (*P. subcordata*), which grows east of the Coast range in southern Oregon and northern California.

Plum Culture in the United States.—Cultivated varieties of at least 12 species of plums are to be found in U.S. orchards or growing in the wild, but most of the important commercial varieties are confined to four of the species already mentioned, namely, *domestica*, *insititia*, *salicina* and *americana*.

It is not known just when European plums were introduced into North America, but probably pits were brought over by the first colonists. It is reported that plums were planted by the Pilgrims in Massachusetts and importations were made by the French into Canada. These European plums have done remarkably well in the new world, and they constitute the most important group grown commercially for canning and drying.

The best known and most important of these groups are varieties of *Prunus domestica*, the European plums and prunes. These are vigorous-growing trees, upright spreading in habit. Unfortunately, they are not well adapted to regions with hot, dry summers or dry, cold winters. They are at home in the northeastern United States and in sheltered sections along the Great Lakes, but they are at their best in the irrigated regions of the intermountain and Pacific coast states, as is evidenced by the extensive production of fresh fruit and dried prunes in this region. The trees do well on medium heavy soils that are well drained. They blossom later than peaches and thus escape spring frosts. The European plums have been under domestication longest, and

the fruits are notable for large size and attractive appearance. They vary in colour from the green and golden yellow of the Reine Claude (greengage) and Yellow Egg groups to the red and dark purple of the Lombard and Italian prune.

The damsons (*P. insititia*) of the old world are quite different from the domestics. The trees are more upright, compact and dwarfish, the leaves and flowers are smaller, and the fruits are small, round and quite tart, so that they are especially suitable for preserves and jams. Varieties of this group are hardy, vigorous and productive, and the trees make good stocks for other species, being adapted to a wide range of conditions and thriving even when they are neglected. The Shropshire and the French are important blue damsons in the United States, while the yellow Mirabelles are popular in France. The demand for varieties of plums of this type is limited, and they are not planted as extensively as those varieties that can be consumed fresh, dried or canned.

The Oriental plums (*P. salicina*) are relatively new to North America, but in the short time since their introduction they have been widely planted and in 1944 ranked second to the domestics in commercial production. The trees are more spreading in habit than the domestics or damsons, and in leaf and fruit characters they are very different, resembling the native American plums. The fruits are very attractive and are characterized by a yellow ground colour overlaid by various shades of red. In some varieties the flesh colour is striking red, whereas fruit of the domestics and damsons is green or yellow. Some newer hybrids of the *salicina* group show distinct superiority in flavour and in commercial possibilities over the early importations. Varieties of this group appear to be widely adapted in the United States except in the very coldest climates. While the quality is not equal to that of the best domestics, and the commercial varieties are not so satisfactory for canning and drying, the fresh fruit is delicious in its blend of flavours. The varieties cross readily with one another and with the native americans. Among the first so-called Japanese plums grown in the United States, Kelsey, Burbank, Abundance and Satsuma are typical. The trees are hardy and productive, and they tolerate a variety of soils as well as climatic conditions. The blossoms open earlier, however, than those of the domestics and damsons and are frequently killed by spring frosts in the eastern part of the United States.

The native American plums were doubtless used for food by the Indians long before the white man set foot on the shores of North America. Reports of early explorers mention the finding of plums growing in abundance. According to the descriptions of the early settlers, these plums were inferior to the domestics of the old world in quality, so that the colonists soon began importing varieties from Europe. As a result, European plums soon became predominant in home fruit gardens as well as commercial orchards in the northeastern United States. Varieties of native species, however, while not grown in commercial orchards, do fill a need in supplying fruit for the home garden in regions where the domestics are not well adapted, as for example in the southwestern and south central United States. American varieties also have been selected for planting in the northern Great Plains where only cold hardy sorts can survive. Varieties like Assiniboin and Cheney of the *P. nigra* group, and Wyant and Desoto of the *americana*, survive in this region.

Hybrids produced by crossing American and oriental varieties have given larger fruited varieties of better quality, also adapted to the colder climates. Waneta and Underwood are two varieties that have been planted in home gardens. Furthermore, American species hybridize with the sand cherry (*P. pumila*), and plant breeders have produced new varieties adapted to cold and dry conditions in the northern Great Plains. Important varieties are Opata, Sapa and Zumbra.

In the United States, as well as in Europe, the plum has long been recognized as one of the most delicious of fruits, and among the stone fruits it ranks next to the peach in commercial production. Many of the varieties of plums cultivated in the United States have been introduced from elsewhere, and when these are added to the native varieties they give plums the largest number

PLUM (*PRUNUS DOMESTICA*) A LONGITUDINAL SECTION THROUGH FLOWER SHOWING RECEPTACLE AND FLOWER PARTS WITH ENLARGED BASAL PORTION OF THE PISTIL THAT DEVELOPS INTO THE FRUIT. B TWIG WITH BLOSSOMS, AND C. FRUITS (DRUPES)

and greatest diversity of kinds and species among the stone fruits. Fortunately varieties can be selected that are adapted to a wide variety of soils and climatic conditions. Plums respond to good soil management practices. When the trees come into bearing they do not require a large amount of pruning and in the home fruit garden can be grown satisfactorily provided insects and diseases are controlled.

Insects and Diseases.—The fruit and tree of the plum are attacked by a number of troublesome insects and diseases that seriously limit production if not controlled by spraying. One of the most serious of the insect pests is the plum curculio, a small beetle that deposits its eggs in the fruit. As the larvae hatch and feed on the fruit, the affected fruits drop prematurely. Sometimes all of the fruits will drop off before harvest. This insect can be controlled by timely spraying with arsenate of lead. Brown rot caused by a fungus that gains entrance through breaks in the skin or through punctures caused by the curculio may also be a serious menace. Fortunately this disease can be controlled by the timely application of fungicides of sulphur or copper. A bacterial leaf disease called bacterial spot, or shot hole, is serious in the more southern latitudes of the United States. Some varieties are quite resistant to this disease while others are susceptible. For the successful production of plums in any region a timely spray program must be followed to protect the fruit and foliage against these insect and disease pests.

Prunes.—Prune is a name given to a plum that can be dried without removing the pit into a firm long-keeping product. This term is frequently applied as a group name to plum varieties that have a sufficiently high sugar content and firm flesh so that they can be preserved by drying. The dried plum of commerce is, therefore, called a prune and only certain varieties have the qualities to make a good dried product. In California most of the plums are dried in the sun, while in Oregon and Washington drying is done in specially built dehydrators, where the drying is done with artificial heat. The growing of plums for the production of prunes in the United States is confined largely to the states of California, Oregon, Washington and Idaho. Agen or French, Italian, Sugar and Imperial Epineuse, all of the European group, are the principal varieties.

In the period 1938-42 the average annual production of prunes on a fresh basis totalled 639,120 tons. Of this amount 48,622 tons produced in the states of Washington, Oregon and Idaho were consumed as fresh prunes. Prunes also make a delectable product when canned, and in the states of Washington and Oregon, where most of the commercial pack of canned prunes is put up, an average of 26,140 tons of prunes were marketed. During this same period, also, an average of 202,080 tons of dried prunes were produced in the four western states.

A large quantity of prunes has been exported in the fresh, canned and dried form. In the years just prior to 1940, before shipping was interfered with by World War II, the total exports on a fresh basis amounted to 275,000 tons. Of this amount 107,000 tons were in the form of dried prunes.

PLUMBAGO: see GRAPHITE

PLUMBING is the system of piping, fixtures and equipment installed in a building for the purpose of (1) supplying water in desired quantities at points of usage, and (2) removing water and water-borne wastes from fixtures, equipment, areas and appliances. Health and safety require that the foregoing be done under the following conditions: (a) without contamination of the supply water through back siphonage or cross connections, and (b) without permitting air, gases, bacteria or vermin inside the soil and waste system to enter the interior of the building. The word "plumbing" is derived from the Latin *plumbum*, meaning the art of working in lead. It originated from the extensive use of lead in the construction of water supply and disposal systems in buildings.

Plumbing systems generally are considered as starting at the supply of water. In municipalities, this is where the supply

branch from the municipal main crosses the property line. The municipal water main customarily is located in a street, highway or easement adjacent to or near the land on which the plumbing is installed. In areas not served by municipal supplies, the plumbing starts at a shallow or deep well, a cistern, a spring or other source of potable water. In municipalities, water is supplied at the main under pressure sufficient to distribute the water to all points of usage in the building served. Where tall buildings or long pipe lines and special usages require a greater-than-normal pressure, this is produced by house pumps or booster pumps. In the case of private water supplies, mechanical pumps deliver water through the plumbing system in the required quantity and at the desired pressure.

Water Supply.—Pumps for supplying water are classified broadly as shallow-well types having a practical working depth of 28 ft or less, and deep-well pumps which are designed to raise water from a depth of more than 28 ft. A shallow-well pump is connected to its water supply by means of a suction pipe, one end of which is submerged in the water. The pump operates on the principle of reducing the pressure in the suction line. The atmospheric pressure on the surface of the water, as a result, forces the water into the suction line and up to the pump mechanism which in turn delivers the water under pressure to a pneumatic storage tank, to an overhead storage tank or directly into the plumbing system.

Deep-well pumps operate on the principle of lifting water either by a valve mechanism generally submerged in the water or by jet propulsion. As in the case of shallow-well pumps, after the water is raised to the level of the pump, it is forced under pressure by the pump to the plumbing system. Hydraulic rams which depend upon the energy of falling water for their motive power also are used for pumping water.

Plumbing Classified.—Plumbing systems are classified broadly as to the type of service rendered. This includes residential plumbing, commercial plumbing, industrial or process plumbing, laboratory plumbing and institutional plumbing.

Individual plumbing systems are divided into the following: (1) the water supply portion, (2) the sewage and waste disposal portion and (3) the venting portion. The functions of the first two divisions of a plumbing system are self-evident. The third or venting portion is necessary in connection with the sewage and waste disposal system.

The reason is that all fixtures and appliances connected to soil and waste lines must be protected by a water seal to prevent the passage of sewer air, gases, bacteria or vermin from the sewer system into the interior of the building. This sealing is accomplished by means of a trap which is a section of the waste line shaped in the form of an "S" or a "P." This trap is located as close to the discharge outlet of the fixture as possible. When water is discharged from the fixture, an amount remains in the trap sufficient to fill a portion of it and thus close off the waste piping. Unless precautions are taken, the flow of water in the soil and waste piping, the discharge from other fixtures in the system or the discharge of the fixture itself may upon the water contents of the trap and thus break the water seal. This is avoided by designing the system so that the pressure within the soil and waste lines will always be equal to the atmospheric pressure outside the soil and waste lines.

Venting System.—The venting system accomplishes this by making outside air available at points where negative pressures otherwise would be induced and by allowing air to be exhausted from the system at points where pressures above atmospheric otherwise would be built up. The venting system, like the soil and waste piping, is concealed within the walls of the building. Its outlets are through the roof. In cold climates, the section of the vent stack which extends through the roof is increased in diameter so that accumulations of frost caused by the condensation and freezing of water from the vapour in the drainage system do not close the opening.

Lead, galvanized iron or copper flashings are formed over the vent stack and around the opening to prevent the leaking of rain water through the roof at that point. Cleanout plugs are located at strategic points in the soil and waste system so that stoppages may be removed if they occur. These plugs usually are placed at points where vertical soil, waste or vent stacks converge with horizontal mains or branches.

Plumbing and Health.—There are very definite health aspects in connection with plumbing. The first consideration is that of maintaining the purity of the water in the supply system up to and including the point where it is discharged or used. There are on record instances of cross connections between potable and non-potable water supplies and between potable water supplies and actual sewage and waste piping. When such cross connections are made, usually there are provisions for separating the two systems by means of valves. In practice, inevitably danger arises from neglect, carelessness or ultimate deterioration of the barriers to contamination, with the result that through cross connections, pure water supplies are mixed with impure water and delivered to points of discharge for human consumption. Accordingly, modern plumbing practice is unalterably opposed to cross connections in plumbing systems.

A second source of contamination of pure water supplies occurs through what is known as back siphonage due to submerged or nearly submerged inlets at fixtures or equipment where water is used. This is based upon the fact that under certain conditions it is possible to induce in water supply lines pressures which are less than atmospheric pressure, otherwise known as partial vacuums.

Back Siphonage.—Unless specific precautions are taken this can occur in plumbing systems under various conditions. For instance,

contamination through cross connections and back siphonage have been authenticated by the United States Public Health service and other authorities and are a matter of public record.

Piping.—The piping for plumbing is in effect a transportation system for the water, the waste, or the gas. It carries water from the water

basin before it is discharged into the main sewer. Removing the grease from the water prevents the solidification and accumulation of the grease in the drainage system, with subsequent stoppages.

Scope of Plumbing.—Plumbing systems include roof drains, area drains, swimming pools, sprinkling systems, stand pipes and hose connections for fire protection, sprinkling systems and hose connections for watering gardens and lawns, and water meters where water is purchased from a municipality or utility. Plumbing also includes sewage disposal systems consisting of septic tanks and distribution lines to disposal fields in installations where municipal sewer mains are not available. Plumbing also includes the insulation of pipes and tanks to prevent the loss of heat from hot water or other liquids carried, to prevent the gain of heat by refrigerated water and to prevent the condensation of water vapour on the surfaces of cold pipes and tanks. Special applications include plumbing for steamships, railroad cars, automobile trailers and airplanes. (W. W. Go.)

PLUM CURCULIO, a North American curculionid beetle, or weevil (*Conotrachelus nenuphar*). This insect is confined to North America east of the Rocky mountains. It ranges as far north as Manitoba and Quebec, and as far south as Victoria, Texas and northern Florida. In this territory it is a serious enemy to stone fruits and also attacks the apple and other pomaceous fruits. It is especially injurious to all varieties of plums, and to peaches and cherries. Its original food was probably the fruit of native *Crataegus*, and wild plum.

The adult curculio is small (about $\frac{1}{2}$ in. long), dark brown in colour, with whitish markings on the thorax and the hinder part of the wing covers. It lays its eggs in holes next to a crescent-shaped cut made in the skin by the beetle's beak. The function of the crescent-shaped cut is to kill the spot in the fruit containing the egg, so that the latter will not be crushed by the rapidly growing fruit. The larvae penetrate the flesh of the fruit, and a number of them may occur in the same plum or peach. On reaching full growth, the larva leaves the fruit and enters the soil, forming a cell in which it transforms successively to the pupa and adult. It rests in the pupal stage for two or three weeks. The resulting beetles feed upon the fruit and foliage until the approach of cold weather, when they enter hibernating quarters in protected places such as under trash in the orchards or in near-by woods. In its more northern range the insect has but one generation annually. In the far south some individuals develop a second generation.

The plum curculio is a great enemy to orchards. In 1947 it was estimated that the annual loss through its work in the United States was continuing to be from \$7,800,000 to \$10,000,000. It has several natural enemies among the hymenopterous and dipterous parasites, and it is destroyed by a few species of predatory insects. The fruit attacked by it often falls to the ground, and under such conditions poultry destroy many of the pests.

Fruit growers rely chiefly on spraying with lead arsenate for the control of the plum curculio. The foliage of the peach is particularly susceptible to injury by arsenicals, although most of this can be overcome by the addition of lime or of zinc sulphate and lime. The sprays on peach are usually combined with a self-boiled lime sulphur or one of the so-called wettable sulphurs to control various diseases, especially brown rot, which often gains entrance into the fruit at points injured by the curculio.

In areas in which a second brood of the curculio develops and where the insect becomes especially abundant, spraying is supplemented by a number of other practices, including the jarring of the trees and the capturing of the beetles on sheets placed underneath, the picking up and destruction of infested wormy drop peaches, and cultivation during the period when the insect is transforming in the ground and when it is readily injured by any disturbance of the soil. Information on the control of the insect may be obtained from state agricultural experiment stations or from the U. S. department of agriculture. (L. O. H.)

PLUMER, HERBERT CHARLES ONSLow PLUMER, 1st Viscount, of Messines, cr. 1929 (1857-1932), British field marshal, was born on March 13, 1857, and entered the army in 1876. He served on the Red sea littoral in 1884, and in 1896 commanded a mounted regiment in the Matabele campaign. Before the outbreak of the South African War (1899) he raised the Rhodesian field force, which he commanded during the early months of the contest. He was promoted major general on the

Softeners and Filters.—Plumbing systems include provisions for removing hardness from water. Such equipment is known as a water softener and is connected in the water supply line. Essentially it consists of a tank filled with a substance which removes from the water the dissolved minerals causing the so-called hardness. The ordinary softener is equipped with valves and accessories which permit the recharging and backwashing of the water-softening substance as required.

Another item of equipment associated with plumbing systems and the purification of the water supply is the water filter, which is designed to remove foreign substances and to purify the water.

All complete plumbing systems include both hot and cold water lines to points where variations in temperatures are desired by the user. In institutions such as hotels, where refrigerated drinking water is distributed to all bedrooms, the water supply is controlled by a water

Water Heating.—The water heating system is one of the most important parts of a plumbing system.

An important part of water heating is control of the equipment to provide predetermined temperatures and to relieve the temperature and pressure inside the water heater in the event they become excessive. Mixing valves, either thermostatic or manual, are designed and installed to control further the discharge temperature of the water at points of usage. Under certain conditions, vacuum relief valves are provided to prevent the collapse of certain types of hot water storage tanks. In some installations, hot water is circulated continuously to outlets so that hot water is available instantly upon opening a faucet.

Wastes from sinks and equipment used in the preparation of food and in the washing of dishes and utensils are discharged through lines separate from the soil system. This is because of the grease content of

conclusion of hostilities

In May 1915 Sir Herbert Plumer was selected to lead the II. Army on the Western Front. His army was not very actively engaged during the remainder of 1915, nor yet in 1916, but on June 7, 1917, Plumer gained a signal victory at Messines (*See YPRES, BATTLES OF*). In November he took charge of the British troops sent to the basin of the Po after the Italian defeat at Caporetto, and in the following March was recalled to Flanders to resume the leadership of the II Army just before the great German offensive started. In the general advance in August, his army took part in the operations for the recovery of Belgian Flanders. At the peace he received a peerage, promotion to field-marshal and a grant of £30,000. He subsequently commanded the British forces on the Rhine for a short time. From 1919 to 1925 he was governor of Malta, and from 1925 to 1928 high commissioner for Palestine. He died July 26, 1932.

PLUMPTRE, EDWARD HAYES (1821-1891), English divine and scholar, was born in London on Aug. 6, 1821. A scholar of University college, Oxford, and a fellow of Brasenose, he was ordained in 1847, and became professor of pastoral theology at King's college, London. In 1863 he was given a prebendal stall at St. Paul's, and from 1869 to 1874 he was a member of the committee appointed by Convocation to revise the authorized version of the Old Testament. He was Boyle lecturer in 1866-67 ("Christ and Christendom"), and Grunfield lecturer on the Septuagint at Oxford 1873-74. After successively holding the livings of Pluckley and Brickley in Kent, he was installed in 1881 as dean of Wells. He died on Feb. 1, 1891.

Plumtre translated the plays of Sophocles (1865) and Aeschylus (1868), and the *Divina commedia* of Dante (1886). In verse his main achievements were *Lazarus* (1864), and *Master and Scholar* (1866). Among his many theological works may be mentioned *An Exposition of the Epistles to the Seven Churches of Asia* (1877), *The Spirits in Prison* (1884), "The Book of Proverbs" (which he annotated in the *Speaker's Commentary*), the "Synoptic Gospels, Acts, and II. Corinthians," in Bishop Ellcock's *New Testament Commentary*, and *Life of Bishop Ken* (1888).

PLUNKET, OLIVER (1639-1681), Irish Roman Catholic divine, was born at Loughcrew, Co. Meath. He was appointed archbishop of Armagh and primate of Ireland in July 1669 and in November he was consecrated at Ghent, reaching Ireland in March 1670. The measures following on the Test Act bore hardly upon him, and in Dec. 1678 he was imprisoned in Dublin Castle for six weeks. Accused of a share in the Irish branch of the "Popish Plot," he was brought to London, and in June 1681 arraigned in the King's Bench, charged with conspiring to bring a French army to Carlingford. He made a good defence, but on the most absurd of evidence the jury convicted him of treason, and on July 1, he was hanged, drawn and quartered at Tyburn.

PLUNKET, WILLIAM CONYNGHAM PLUNKET, 1ST BARON (1764-1854), Irish lawyer, orator and statesman, was born in the county of Fermanagh in July 1764, the son of a Presbyterian minister, and studied at Trinity college, Dublin. Having entered Lincoln's Inn in 1784, Plunket was called to the Irish bar in 1787. He gradually obtained a considerable practice in equity and was made a king's counsel in 1797.

In 1798 he entered the Irish parliament as member for Charlemont. He was an anti-Jacobin Whig of the school of Burke, and a fervent Irish patriot. But he was a sincere admirer of the constitutional government of England as established in 1688, he even justified the ascendancy it had given to the Established Church, although he thought that the time had arrived for extending toleration to Roman Catholics and dissenters. To transfer it to

universally recognized. His speeches raised him immediately to the front rank of his party; and when Grattan re-entered the moribund senate he took his seat next to Plunket, thus significantly recognizing the place the latter had attained.

After the union Plunket returned to the practice of his profession, and became at once a leader of the equity bar. In 1803 he was selected as one of the Crown lawyers to prosecute Emmet. For his speech on this occasion he was exposed to much obloquy, and more especially to the abuse of Cobbett, against whom he brought a successful action for damages. In 1803, in Pitt's second administration, he became solicitor-general, and in 1805 attorney-general for Ireland, and he continued in office when Lord Grenville came into power in 1806. Plunket held a seat in the Imperial parliament during this period, and there made several able speeches in favour of Catholic emancipation, and of continuing the war with France; but when the Grenville cabinet was dissolved he returned once more to professional life.

In 1812 he re-entered parliament as member for Trinity college, and identified himself with the Grenville or anti-Gallican Whigs. He was soon acknowledged as one of the first orators, if not the first, of the House of Commons. In 1822 Plunket was once more attorney-general for Ireland, with Lord Wellesley as lord-lieutenant. One of his first official acts was to prosecute for the "bottle riot," an attempt on his part to put down the Orange faction in Ireland. He strenuously opposed the Catholic Association, which about this time, under the guidance of O'Connell, began its agitation. In 1825 he made a powerful speech against it, thus the curious spectacle was seen of the ablest champion of an oppressed church doing all in his power to check its efforts to emancipate itself. In 1827 Plunket was made master of the rolls in England; but, owing to the professional jealousy of the bar, who regarded an Irishman as an intruder, he resigned in a few days. Soon afterwards he became chief justice of the common pleas in Ireland, and was then created a peer of the United Kingdom. In 1830 he was appointed lord chancellor of Ireland, and held the office, with an interval of a few months only, until 1841, when he finally retired from public life. He died on Jan. 4, 1854, and was succeeded by his eldest son, Thomas Spen Plunket (1792-1866), bishop of Tuam, as 2nd baron. *See the Life of the First Lord Plunket* (1869), by his grandson, David Robert Plunket.

PLUNKETT, SIR HORACE (CURZON) (1854-1932), K.C.V.O. (1903), son of the 13th Baron Dunsany, was born on Oct. 24, 1854, and educated at Eton and Oxford. After engaging in cattle ranching for ten years, his interest in agriculture led him to devote himself to the promotion of agricultural co-operation, and in 1894 he founded the Irish Agricultural Organization Society. As a member of parliament from 1892 to 1900, he strongly advocated the cause of agriculture, and in 1899 he was appointed vice-president of the department of agriculture and technical instruction for Ireland. Two years later he became commissioner of the Congested Districts Board in Ireland. He was elected F.R.S., in 1902, and in 1919 endowed a trust, known by his name, for the development of agriculture. He presided over the Irish Convention of 1917-18, and was a Senator (1922-23) of the Irish Free State. He died March 26, 1932.

His works include, *Ireland in the New Century* (1904); *The Rural Life Problem of U.S.* (1910); *Some Tendencies of Modern Medicine* (1913); and *A Better Way* (1914).

PLURALISM. The term describes certain schools of philosophical thought. It is, indeed, distinctive of one of the two groups into which metaphysical theories may be divided by what is perhaps the profoundest of the many differences apparent between the various directions taken by the speculations of eminent philosophers. In short, every philosophical system is either singularistic or pluralistic; that is, it takes for its starting point, and for the guiding principle which directs its development, the idea of the essential unity of reality, or, on the other hand, it regards as fundamental the characters of diversity and plurality which are everywhere in evidence in the realms open to observation.

Nevertheless, the term "pluralism" is by no means definite in meaning. On the contrary it is ambiguous and capable of philosoph-

saries was Plunket, whose powers as a great orator were now

ically of a number of different meanings, each of which, however, refers to some peculiarly radical distinction in philosophic thought. But, as so frequently happens in such cases, the word has tended more and more to become restricted in meaning to one particular type of theory. This is perhaps an example of the survival of the fittest, for it is probable that what is nowadays generally meant by "pluralism" is capable of giving a better account of itself and of putting up a stronger defence than any of the other kinds of theory which may be included within the scope of the term as literally interpreted.

QUALITATIVE PLURALISM

In the first place the term "pluralism" may have a *qualitative* meaning. One of the oldest problems of philosophy is that which concerns itself with the question whether the ultimate fundamental stuff, which is the ground of reality, is a single substance or includes a number of substances with differing attributes. Theories founded on the supposition that there are many ultimate substances, or at any rate more than one, are "pluralistic" in the qualitative sense of the term.

As a matter of fact only one theory of this type has ever been seriously propounded and effectively defended. This is the theory of "dualism," which holds that there are two kinds of fundamental substance. The two substances of dualism are commonly termed "mind" and "matter," and the distinctive attributes assigned to them are not merely different but are strictly incomparable with one another. The essential property of "mind" is thought, that of "matter" is extension. Dualism, which probably approximates more nearly than any other metaphysic to the practical, if unformulated, belief of the ordinary man who does not concern himself with philosophical analysis, recurs at intervals, in one form or another, throughout the history of speculative thought. But the clearest statement and the most able defence of it are to be found in the writings of Descartes (1596-1650), with whom modern philosophy is generally regarded as beginning. Descartes starts from the existence of the self. The fact of consciousness is, he holds, quite undeniable. He then proceeds to deduce the existence of God from the presence in our minds of an idea of God which embraces attributes so exalted as to make it inconceivable that the idea could have originated in anything so limited as the human mind. Accordingly its presence can only, he thinks, be explained by an external cause, namely, God himself. From this it is an easy step to the existence of matter. For God, being perfect, would not falsify our clearest perceptions, and among these is the perception of matter. Moreover, the attribute of matter which is most distinctly apparent to us is its extension, or occupancy of space, and this must accordingly be regarded as the essentially distinctive property of material substance.

We need not stop to consider in detail the defects of this argument which Descartes elaborated with remarkable thoroughness and ingenuity. It is sufficient to point out that the essential feature of his analysis, namely, the division of reality into mind and matter, was at fault. Matter as he conceived it, so far from being a substance and therefore concrete in the most complete sense, was altogether abstract. The same is true, though to a lesser extent, of his conception of mind. In fact the dualistic division of the universe into mind and matter, though it starts, as all philosophical theories must start, from the elements given in immediate experience, proceeds by abstracting some of these elements and elevating them to the position of concrete entities in their own right. This process, useful and indeed necessary for the purposes of such bodies of knowledge as the special sciences, is too artificial to yield anything of metaphysical value. Metaphysics, to achieve its end, must keep in constant touch with the concrete, that is, with experience. But a process of reasoning like that, adopted by Descartes inevitably tends further and further away from the concrete to the abstract. The practical consequences of this for dualism are seen in its inability to attack with any success such problems as those concerned with the relation of body and mind, the nature of the external world, and the question as to how knowledge is possible at all.

Dualism is the only form of qualitative pluralism which has ever been seriously developed. (But it should perhaps be pointed out that the cosmology of Empedocles [490-430 B.C.], with its four elements, earth, air, fire, water, together with the qualitative atomism of his follower Anaxagoras, who regarded the universe as made up of a countless number of qualitatively simple elements, are really forms of qualitative pluralism.) It is true that some of the doctrines of theosophy and allied systems appear to lead to a pluralism of more than two kinds of substance, but these doctrines are essentially speculative and have never been developed in a form sufficiently definite, nor defended by arguments sufficiently logical, to affect at all seriously the development of philosophical thought. We may therefore conclude this brief survey of qualitative pluralism and pass on to consider quantitative pluralism.

QUANTITATIVE PLURALISM

Quantitative pluralism includes all those theories which hold reality to be made up of a number of relatively independent substantial entities, each of which exists, at any rate to some extent, in its own right. Quantitative pluralism is thus sharply contrasted with those forms of singularism or absolutism which regard reality as ultimately consisting of a single individual being, of which the many and diverse elements which seem to exist in the world are no more than mere appearances, qualities, or modes, having no real existence in themselves. This contrast has sometimes been expressed by saying that whereas, according to pluralism, the multitude of entities which appear to find a place in the universe have a "substantial" existence, according to singularism their existence is merely "adjectival" as attributes or aspects of the one real being.

We may classify types of quantitative pluralism according to their doctrine regarding the substance composing the real entities which they postulate. This substance may be material, spiritual (or mental), or it may be neutral in the sense that its essential character is unknown, or, if known in part, cannot be placed definitely in any particular category.

Neutral Pluralism.—The first kind of neutral pluralism, where the nature of the ultimate substance of which individual entities are composed is taken as unknown, though not altogether untenable, is philosophically barren and need not detain us. Its best known exponent is Herbert, who contended that reality is ultimately made up of a number of independent entities, of the inner nature of which we could know nothing, although they were the ground of all the facts of which knowledge was possible. Herbert's theory did not seriously affect the course of metaphysical speculation. It was largely a reaction against the philosophy of Hegel (1770-1831).

The second kind of neutral pluralism, in which the nature of the ultimate reality is regarded as known, at least in part, but as not definitely classifiable, has been developed only in comparatively recent years. William James (1842-1910), foremost and most original of American philosophers, seems to have been the first to have given it clear expression, though he was probably influenced to some extent by the speculations of the German physicist Ernst Mach. James based his belief on what he himself described as a "radical empiricism." He held essentially that the world of which we have knowledge is made up of a number of fundamental elements which may be taken as arranged in different types of patterns or sequences. If the elements are set out in one way we get the kind of structures or series which make up the contents of what we call "minds." Another method of selecting the elements will give the type of arrangements which constitute those entities which we know as material objects or physical events. Yet the elements of a pluralistic universe of this kind are not to be regarded as themselves essentially mental or material—they are of "neutral" stuff. Incidentally James was the first thinker to give the term "pluralism" currency among English-speaking philosophers, though in Germany we find it even as early as Wolff, the disciple of the great Leibniz (1646), to whom we shall refer later.

More recently still, a neutral pluralism which in some respects

exhibits a strong family likeness to that of William James has been developed in England by Bertrand Russell, who describes his own theory by the name "logical atomism." Russell's procedure consists essentially of an exceptionally detailed analysis of the material open to immediate observation, especially the particulars given in sensation and in imagery, followed by an attempt to build up from this material alone constructions corresponding to the fundamental concepts characteristic of physics and of philosophy, or to such among these concepts as analysis may show to be valid within their limits. Russell has applied his method to the analysis both of "mind" and of "matter." Current developments in the theories of some of the American neo-realists seem also to be moving along rather similar lines.

There can be no doubt that a neutral pluralism of the type we have outlined is in many respects an extremely powerful theory. Not only does it establish a metaphysical position which calls for serious consideration, but it introduces into the philosophical world an analytic technique the value of which it would be difficult to overestimate. It is not possible to undertake a detailed criticism here; but it is probable that the chief objections to current expositions of the theory are to be found in the fact that they dispose of some of the traditionally pressing questions of metaphysics with arguments which may be regarded as unduly facile, to say the least, while many will feel that most of the really ultimate problems are left untouched. No doubt the supporters would retort that these problems are insoluble, and no more time should be wasted on them.

Material Pluralism.—There remain for consideration material pluralism and spiritual pluralism. For the material pluralist the world consists; in the last analysis, entirely of particles or bodies, the properties of which are among those commonly associated with the concept of matter, in particular mass (or, perhaps, electric charge); position and (perhaps) extension in space, and position and (perhaps) extension in time.

The earliest philosophers to give coherent expression to a theory of this kind were the Greeks, Leucippus and Democritus (about 460–350 B.C.). We owe to Leucippus the first clear statement of philosophic materialism, namely, the reduction of all reality to the primary qualities of matter. The denial of qualitative differences between the elements was combined with an atomic theory of matter which was conceived as split up into an infinite number of minute reproductions of itself, these "atoms" being invisible to the eye, eternal and unchangeable, and differing from one another only in shape and size. The scientific development of this point of view by Democritus was an outstanding philosophical achievement which marked a definite stage in the progress of the speculative thought of antiquity.

Although material pluralism, or atomistic materialism, suffered long periods of eclipse during the middle ages and the Renaissance, it has been revived at intervals and was finally given complete and powerful expression as a result of the great advances made during the last century in physical and biological science. Twentieth century materialism is chiefly associated with the name of Herbert Spencer (1820–1903), who developed an extremely comprehensive system based on three current doctrines which were just then achieving remarkable triumphs in the respective realms of chemistry, physics and biology. These doctrines were the atomic theory, the principles governing the distribution and conservation of energy, and the Darwinian theory of evolution by natural selection. In a swift and temporarily overwhelming advance, philosophic materialism reached its zenith. But its success was a transient one. Before the end of the century it was already beginning to stagger under the powerful blows of its opponents, and during the years that have since elapsed it is based as regarded as a tenable metaphysical theory. It can probably be safely stated that it will never again be revived unless it be in so changed a form as to be unrecognizable. Briefly, its downfall may be said to be due to three inherent defects. In the first place the concepts and principles on which it is based are merely descriptive in character, that is, they do no more than give an account of what actually occurs, or is presumed to occur, in the world, and do not even begin to pro-

vide any kind of genuine explanation of reality. Not only this, but secondly, modern analysis has shown that most of the conceptions of conventional materialism, so far from corresponding to anything really concrete, are most probably no more than abstractions from, or constructions made up of, the content perceived by minds in sense-experience or perception. Thirdly, materialism has never yet been able to give an account of the origin of mind which could possibly be accepted as a satisfying one, while its consequent attempts to dismiss mind as unreal or at most real but ineffective, have been extremely facile and altogether unconvincing.

Spiritual Pluralism.—There remains spiritual pluralism, and it is to this type of theory that the name "pluralism" is most commonly understood to apply at the present time. It is the belief that the world consists ultimately of an indefinite number of beings, essentially spiritual in character. Its origin can be traced back, albeit in a vague form, even to the obscure hylozoism of the ancients, who regarded all nature as alive and informed with a countless number of animate beings, to whose activities all her manifestations were due. But at this epoch the distinction between the physical and the mental had not begun to emerge clearly, and only when this occurred was it possible for the development of spiritual pluralism to take place.

But it was not till the coming of Leibniz (1646) that spiritual pluralism at last received definite and coherent statement, together with logical development. Leibniz started from a conception of mind directly opposed to that which had been given currency by Locke and the English empiricists. The latter regarded the mind as a passive receiver of impressions from objects external to it. But Leibniz realized that it is the essence of mind to be active. In his famous work, the *Monadology*, he elaborated the theory that reality consists of an infinite number of individual forces or agents, psychic in nature, which he termed "monads." These individual minds or spirits exhibited every degree of mental development and complexity, from that of beings even higher than man (the "angels") right down to that of psychic entities of so low an order that Leibniz described their being as a *mens momentanea* or mere flash of conscious awareness. In this hierarchy of mind a complete continuity from one level of development to another was postulated.

Leibniz conceived each monad as reflecting within itself the rest of the universe from its own particular "standpoint." The perceptions of each monad were partly conditioned by its particular level of development, and constituted the appearance to it of all the other monads. But Leibniz met with great difficulty at this point. He had conceived the monads as absolutely independent reals with no ground of connection between them. But how could the appearance of beings other than itself arise in such an isolated entity as a monad, which, being "windowless" (as Leibniz put it), was impervious to external influence? Leibniz tried to solve this difficulty by his doctrine of "Pre-established Harmony," which involved the introduction of the idea of God into his system. According to this doctrine the development of the universe is the working out of a plan conceived by God when he created the monads. Each monad contains the principle of its own development, but the course of that development is so arranged that, at any instant, the unfolding order of phenomena within each monad is an accurate representation of the rest of the universe at that instant. This may be illustrated by the analogy of a number of clocks set going by the watchmaker so as always to keep time with one another, though actually there is no connection between them.

The spiritual pluralism of Leibniz, though it continued to exert a dominant influence in Germany until the time of Kant (1724–1804), did not find much vogue among English-speaking philosophers until comparatively recent times. During the last years of the 19th and the early years of the present century, however, it was adopted and developed, in the reaction against crude materialism, by one or two influential thinkers, including Howison in America and the late James Ward in England. Though his system is founded on that of Leibniz, Ward introduced very considerable modifications, exposing the weaknesses of the orig-

nal theory and endeavouring to eliminate them. He pointed out that pluralism has to explain away three difficulties. Two of these are concerned with what he calls respectively "the upper limit" and "the lower limit" of pluralism. If we are to make reality at all intelligible we must, with Leibniz, postulate continuous development of the monads. But from what did this development originate and how was it set going? We can trace it downwards to ever lower levels, but we cannot find within it the principle and the explanation of its own origin. On the other hand, whither is it tending? A mere plurality of independently developing beings cannot contain any indication of a satisfying explanation which shall harmonize, and give point to, the manifold separate developments. Thirdly, there is the old difficulty, encountered by Leibniz, as to the impossibility of interaction between the monads if these are really independent individuals.

Ward comes to the conclusion that a thoroughgoing pluralism is untenable. It must be supplemented by a principle of unity which, while it does not destroy the conception of the monads as real individuals having a "substantial" and not a merely "adjectival" existence, at the same time enables us to get rid of the difficulties raised by a pure pluralism. Ward finds his unifying principle in a theistic theory, conceiving God as a supreme being transcending the world of the many and yet immanent in it. On the one hand God, as creator, originates monadic development; on the other, He stands as the supreme unity to a harmonious co-existence with whom that development is for ever more nearly approaching. Moreover, as immanent in the world, He mediates the interaction between the monads.

It is impossible to enlarge here upon the metaphysical theory thus outlined. It must suffice to point out that it has many important possibilities and merits serious consideration. Moreover, it is a healthy corrective to the cruder forms of materialism, for while the latter are ultimately based on conceptions which can be shown to represent pure abstractions, spiritual pluralism starts from a fact of which each of us is certain from his own immediate experience, namely, the concrete existence of such a thing as an individual "mind," or better, perhaps, "spirit."

A form of spiritual pluralism is being developed in America by the Personal Idealists, while in England Wildon Carr has propounded an interesting monadism with especial reference to the philosophical importance of Einstein's principle of relativity and its apparent implication of the reality and profound significance of the existence of individual observing minds.

PLURALITY, a term applied particularly to the holding of two or more offices by the same person (called then a *pluralist*). In ecclesiastical law, plurality, or the holding of more than one benefice or preferment, was always discountenanced, and is now prohibited in England by the Pluralities Act, 1838, as amended by the Pluralities Act, 1850, and the Pluralities Acts Amendment Act 1885. By the latter act a provision was made that two benefices might be held together, by dispensation of the archbishop on the recommendation of the bishop, if the churches be within four miles of each other, and if the annual value of one does not exceed £200. (See **BENEFICE**.)

In the United States, the term is used in election law to denote the number of votes which a candidate has received for a public office in excess of the number received by any one of two or more other candidates.

PLURALITY OF CAUSES, in logic, is the view that one and the same kind of effect can be produced in different cases by different causes. This is quite distinct from the question whether the cause of an effect is as a rule a complex or multiplicity of several or many constituent or contributory factors or conditions. Assuming the complexity of each cause, there still remains the further question whether any one of several sepa-

rate causes can produce the same kind of effect as another. In other words can one cause ever act vicariously for another? (Hence the alternative, and less ambiguous name, "vicarious causes.") J. S. Mill is the best known advocate of the doctrine of plurality of causes. Examples taken from daily experience seem to support the view. Many different causes can produce death for example. For most practical purposes the doctrine holds good. The whole system of substitutes, in peace and in war, is based on it. But for practical purposes many effects are sufficiently similar, although they are really very different when closely scrutinized. The total state called death is very different according as one cause or another led to it. The holding of coroners' inquests is based on the assumption that a close examination of the state of a dead body can help to determine the precise cause of death in each case. Similarly with all cases in which details matter. The total effect produced by one kind of cause is never precisely the same as that produced by any other. So that strictly speaking the doctrine of plurality of causes is not true. But where the interest is centred in broad kinds of effect, and differences of detail do not matter much, there the doctrine holds good for all practical purposes.

See J. S. Mill, *System of Logic* (1875 etc.); J. Venn, *Empirical Logic* (1889); J. Walton, *Manual of Logic* (1896).

PLUSH. Plush fabrics are characterized by a fur-like or velvet pile surface somewhat typical of the short hairy pelts of certain animals as, for example, the seal and otter. A plush pile surface is developed in woven fabrics by causing a series of tufts of pile to project more or less vertically from a foundation texture. The tufts of pile virtually consist of short lengths of warp threads usually of silk, artificial silk or mohair yarn interwoven with the foundation fabric in such a manner that the tufts of pile are looped under the picks of weft by which they are securely retained in the fabric.

PLUTARCH (Gr. Πλοταρχος) (c. A.D. 46-120), Greek biographer and miscellaneous writer, was born at Chaeronea in Boeotia. After having been trained in philosophy at Athens he travelled and stayed some time at Rome, where he lectured on philosophy and undertook the education of Hadrian. (There seems no authority for this statement earlier than the middle ages.) Trajan bestowed consular rank upon him, and Hadrian appointed him procurator of Greece. He died in his native town, where he was archon and priest of the Pythian Apollo. In the *Consolation to his Wife* on the loss of his young daughter, he tells us (§ 2) that they had brought up four sons besides, one of whom was called by the name of Plutarch's brother, Lamprias. We learn incidentally from this treatise (§ 10) that the writer had been initiated in the secret mysteries of Dionysus, which held that the soul was imperishable. He seems to have been an independent thinker rather than an adherent of any particular school of philosophy. His vast acquaintance with the literature of his time is everywhere apparent.

The celebrity of Plutarch, or at least his popularity, is mainly founded on his 46 *Parallel Lives*. He is thought to have written this work in his later years after his return to Chaeronea. His knowledge of Latin and of Roman history he must have partly derived from some years' residence in Rome and other parts of Italy (*Demosth.* § 2), though he says he was too much engaged in lecturing (doubtless in Greek, on philosophy) to turn his attention much to Roman literature during that period.

Plutarch's design in writing the *Parallel Lives*—for this is the title which he gives them in dedicating *Theseus* and *Romulus* to Sossius Senecio—appears to have been the publication, in successive books, of authentic biographies in pairs, taking together a Greek and a Roman. In the introduction to the *Theseus* he speaks of having already issued his *Lycurgus* and *Numa*, viewing them, no doubt, as bearing a resemblance to each other in their legislative character. *Theseus* and *Romulus* are compared as the legendary founders of States. In the opening sentence of the life of Alexander he says that "in this book he has written the lives of Alexander and Caesar" (Julius), and in his *Demosthenes*, where he again (§ 1) mentions his friend Sossius, he calls the life of this orator and Cicero the fifth book. (It is quite evident that the

original order of the books has been altered in the series of *Lives* as we now have them.) It may, therefore, fairly be inferred that Plutarch's original idea was simply to set a Greek warrior, statesman, orator or legislator side by side with some noted Roman celebrated for the same qualities, or working under similar conditions. Nearly all the lives are in pairs, but the series concluded with single biographies of Artaxerxes, Aratus (of Sicyon), Galba and Otho. In the life of Aratus, not Sossius Senecio, but one Polykrates, is addressed.

The *Lives* are works of great learning and research, long lists of authorities are given, and they must for this very reason, as well as from their considerable length, have taken many years in compilation. It is true that many of the lives, especially of Romans, do not show such an extent of research. But Plutarch must have had access to a great store of books, and his diligence as an historian cannot be questioned, if his accuracy is in some points impeached. From the historian's point of view the weakness of the biographies is that their interest is primarily ethical. The author's sympathy with Doric characters and institutions is very evident; he delights to record the exploits, the maxims and virtues of Spartan kings and generals. This feeling is the key to his apparently unfair and virulent attack on Herodotus, who, as an Ionian, seemed to him to have exaggerated the prowess and the foresight of the Athenian leaders.

The voluminous and varied writings of Plutarch exclusive of the *Lives* are known under the common term *Opera moralia*. These consist of above 60 essays, some of them long and many of them rather difficult, some too of very doubtful genuineness. Their literary value is greatly enhanced by the large number of citations from lost Greek poems, especially verses of the dramatists, among whom Euripides holds by far the first place. The principal treatises in the *Opera moralia* are the following:—

On the Education of Children; How a Young Man Ought to Hear Poetry, on the moral aspect of Homer and the tragedians, with quotations *On the Right Way of Hearing* (Περὶ τοῦ ἀκούειν) is another educational essay. Among the moral essays may be included *How a Platterer may be Distinguished from a Friend*, *How One may be Conscious of Progress in Goodness*, addressed to Sossius Senecio, consul under Nerva and Trajan, three short essays, *On Having many Friends*, *On Chance* and *On Virtue and Vice*, mainly valuable for quotations from poets otherwise lost, *Advice to the Married*, *On the Late Vengeance of the Deity*, *On the Genius of Socrates*, *On Superstition*, *On Envy*, a fine essay plentifully illustrated with quotations; *The Amorous Man*, and the *Gryllus*, an entertaining dialogue proving the moral superiority of many animals over man. The speakers are Circe, Odysseus, and a pig; the pig wins.

Another group includes some physical treatises such as *Precepts about Health*, which do not often coincide with modern ideas, *On the Race of the Moon's Disk*, which throws light on ancient astronomical theory, *Whether Land or Water Animals are the Cleverer*; *Whether Water or Fire is the More Useful*; *On Primary Cold*, *Questions Naturales* and *On Flesh Eating*. The historical treatises include *On the Fortune of the Romans*, two essays on the career of Alexander, *Whether the Athenians were More Renowned for War or for Wisdom*, and the famous *De Maliguitate Herodoti*, charging Herodotus with unfair treatment of the non-Ionic States. There are also a purely metaphysical work, the *Platonic Questions*, and two political treatises, *Should a Man Engage in Politics when No Longer Young?* and *Political Precepts*. There are also two *Consolations*, one to Apollonius for his son, and one to his own wife for their daughter. There remains a group of his most valuable and interesting works, on archaeological questions generally, and especially religious history. These include *On Isis and Osiris*, *On the Cessation of Oracles*, *On the Pythian Responses* (an appendix to the last), and *On the E at Delphi*, of the exclusively ritual discussions; and two miscellaneous works, which contain a vast collection of information and discussions on points of almost every kind, the *Symptotica* (9 books), and the *Quaestiones Romanae et Graecae*, which is of considerable importance to classical archaeology. There is also the collection of *Short Sayings*, divided into (1) of kings and commanders (2) of Spar-

tans, and (3) of Spartan women. Doubt is thrown on the validity of *The Banquet of the Seven Wise Men*, *On Fate*, *Parallels*, *On Accepted Opinions* and *The Lives of the Ten Orators*. *Βιβλιογραφία*—*Édition princeps*, by H. Suphane (1872), other complete editions by J. J. Reiske (1774–85), J. G. Huetten (1791–1804), T. Dohner and F. Dübner (1846–55). Of the *Lives*, there are editions by A. Coray (1809–14), C. Sintenis (1839–46, ed. mun. 1874–81), and

counselors (1874–78). Mention may also be made of P. Holland's *Roman Questions*, edited with introductory dissertations by F. B. Jevons (1892), *Roman Problems*, with essay on "Roman Worship and Belief," by G. C. Allen (1904); H. J. Rose, *The Roman Questions of Plutarch* (Text and Commentary, 1914), *De la Musique*, ed. H. Weil and Th. Renach (1900), J. Oakesmith, *The Religion of Plutarch as expounded in his Ethics* (1902); Archbishop Trench, *A Popular Introduction to Plutarch* (1873), O. Gifford, *De la Morale de Plutarque* (1866), R. Volkmann, *Leben, Schrift und Philosophie des Plutarch* (1869), R. Bury, *Plutarch* (1912). The earlier literature of Plutarch is very extensive, for which W. Engelmann, *Scriptores graeci* (1881), may be consulted.

PLUTARCH, of Athens (350?–430), Greek philosopher, head of the Neoplatonist school at Athens, was the son of Nestorius. His main principle was that the study of Aristotle must precede that of Plato, and that the student should be shown the fundamental points of agreement between them. With this object he wrote a commentary on the *De anima* which was the most important contribution to Aristotelian literature since the time of Alexander of Aphrodisias. This critical spirit reached its greatest height in Proclus, the ablest exponent of this latter-day syncretism. Plutarch was versed in all the theurgic traditions of the school, and believed in the possibility of attaining to communion with the Deity by the medium of the theurgic rites. Unlike the Alexandrists and the early Renaissance writers, he maintained that the soul which is bound up in the body by the ties of imagination and sensation does not perish with the corporeal media of sensation. He interposed between sensation and thought the faculty of Imagination, which is the activity of the soul under the stimulus of unceasing sensation, and provides the raw material for Reason. Reason is present in children as an inoperative potentiality, in its pure activity, it is the transcendental or pure intelligence of God. See Mannus, *Vita Procli*, 6, 12, Zeller's *History of Greek Philosophy*.

PLUTO, a euphemistic name for the Greek god of the lower world (Gr. Πλούτων), properly Hades, Aides or Aidoneus, "the Unseen." He was the son of Cronus and Rhea, and brother of Zeus and Poseidon. Having deposed Cronus, the brothers cast lots for the kingdoms of the heaven, the sea, and the infernal regions. The last, "the house of Hades," sometimes loosely called Hades, fell to Pluto. Here he ruled with his wife, Persephone, over the other powers below and over the dead. He is stern and pitiless, deaf to prayer or flattery, and sacrifice to him is of no avail, only the music of Orpheus prevailed upon him to restore his wife Eurydice. His helmet, given him by the Cyclopes after their release from Tartarus, rendered him invisible (like the Tarn—or Nebelkappe of German mythology). Being feared, he is usually alluded to by euphemistic epithets: Polydectes (the receiver of many), Clymenus (the Illustrious), Eubulus (the giver of good counsel). But, perhaps by contamination with a god of the fertility of the earth, he is also Pluto, the "giver of wealth" (a name that first occurs in the Attic poets of the fifth century), and at most of the centres of his cult he was so worshipped. At Elis alone he was Hades, the god of the dead. The plants sacred to him were the cypress and narcissus; black victims were sacrificed to him, as to all underworld powers. In art he was represented like Zeus and Poseidon, but sterner, his attributes are a sceptre and Cerberus: he carries the key of the world below

and is frequently in company with Persephone

PLUTO is the outermost known planet of the solar system, ninth in order of distance from the sun. Its mean distance from the sun is 39.5 times that of the earth, its period of revolution 248 years. Its orbit is so eccentric ($e=0.25$), that at perihelion passage, as in 1989, Pluto is closer than Neptune to the sun. The inclination of its orbit (17°) is such, however, that the orbits of ascending node ($=110^\circ$) are such, however, that the orbits of Neptune and Pluto do not intersect. Pluto is so faint, about 15th magnitude, that a telescope of 20-in. aperture is necessary to see it easily. Because it is so small and so faint its diameter has not been measured, nor has its spectrum been obtained except on a very small scale. The measures of its colour show that Pluto is yellower than Neptune. From the brightness and an assumed albedo (reflecting power) it is inferred that Pluto is probably smaller than the earth, possibly even smaller than Mars. The mass of Pluto, which has been determined from its disturbing effect on Neptune, is about 0.9 that of the earth.

Pluto was discovered as a result of a systematic search instituted by Percival Lowell who thought that the motion of Uranus gave evidence of a trans-Neptunian planet. (*Memoirs of the Lowell Observatory*, vol. 1, 1915) The discovery was made on Feb. 18, 1930, by Clyde William Tombaugh of the Lowell observatory, while systematically comparing photographs taken on Jan. 23 and 29, 1930, in the search for the planet (*Scientific Monthly*, vol. 34, Jan. 1934). He recognized the new planet by its motion which, near opposition, is much slower than that of the numerous asteroids also recorded on the photographs. When discovered, Pluto was close to the star δ Gemma, near the position predicted by Lowell.

Other investigators had also predicted the position of a trans-Neptunian planet on the basis of its gravitational effects. Such a prediction by William Henry Pickering based on the motion of Neptune (*Harvard Annals*, 82, No. 3, 1910) also gave a position quite close to the correct one. In spite of the fact that the planet was found near the position indicated by these computations, many astronomers think that the finding of Pluto was due to the thoroughness of the observational search rather than to the theoretical prediction of its position. Considering the small mass of Pluto and the probable errors in the observed and computed positions of Uranus and Neptune, they believe that the discrepancies prior to 1915 were so small that the direct solution of the problem would be indeterminate. (S B N)

PLUTO MONKEY, a guenon, *Cercopithecus mitis*, which takes its name from the black fur of the under parts, passing into blackish gray on the head and back. The violet-coloured face is fringed by large bushy whiskers and surmounted by a white band above the brows. The typical form extends from the Congo to Nyasaland and Angola.

PLUTONIUM. The element plutonium has the chemical symbol Pu and the atomic number 94. It was given its name after the planet Pluto to follow the convention which was used in the naming of uranium and neptunium. Since all of the isotopes are produced synthetically, the atomic weight depends on the particular isotopic composition of any given sample, which in turn depends on the source of the sample. Plutonium occupies a position in the periodic system of the elements as the fifth member of a transition series, the actinide series, which includes the heaviest known elements and in which an inner electronic shell (the 5f shell) is being filled. The electronic structure of the gaseous atom is probably that of the element radon (atomic number 86) plus five 5f, one 6d and two 7s electrons although it may possibly contain six 5f and no 6d electrons. All of the isotopes are radioactive.

History.—The element plutonium was discovered late in 1940 at the University of California in Berkeley, Calif., by G. T. Seaborg, E. M. McMillan, A. C. Wahl and J. W. Kennedy. The first isotope to be discovered was the one of mass 238 formed by the bombardment of natural uranium with 15-Mev deuterons in the 60-in. cyclotron. This led to the production of an isotope, Pu^{238} , of the element with atomic number 94 which decays with a 20-day half-life by the emission of beta particles to the isotope Pu^{239} . The latter decays by the emission of alpha particles with a half-life of about 90 yr.

TABLE I—Known Isotopes of Plutonium and Some of Their Radioactive Properties

Isotope	Half life	Type and energy of radiation (Mev)
Pu^{238}	36 min	$\text{EC}^* (\approx 98\%)$, $\alpha^* (\approx 2\%)$ 6.58
Pu^{239}	0.03 hr	$\text{EC} (\approx 62\%)$, $\alpha (\approx 4\%)$ 6.19
Pu^{240}	26 min	$\text{EC} (\approx 99\%)$, $\alpha (\approx 0.001\%)$ 5.85
Pu^{241}	3.7 yr	$\text{EC}^* (\approx 99\%)$, $\alpha^* (\approx 1\%)$ 6.51
Pu^{242}	470 days	$\text{EC}^* (\approx 99\%)$, $\alpha^* (\approx 1\%)$ 6.51
Pu^{243}	60 yr	α 5.40 (71%), 5.45 (29%)
Pu^{244}	8.8 million yr	α 5.47 (100%), 5.14 (100%), 5.07 (100%)
Pu^{245}	1,600 yr	α 5.70 (74%), 5.12 (26%)
Pu^{246}	24 yr	α (100%) 5.07, 4.4 (100%) 4.91
Pu^{247}	5.2 x 10 ⁵ yr	α 5.48
Pu^{248}	5.0 hr	α 5.5

*EC=orbital electron capture

α =alpha particle emission

The isotope of plutonium which is of greater importance is the one with mass number 239. This isotope, which decays by the emission of alpha particles with a half-life of about 24,000 yr, was discovered at the University of California in the spring of 1941 by J. W. Kennedy, G. T. Seaborg, E. Segré and A. C. Wahl. Its importance stems from its property of being fissionable with slow neutrons, a property which makes it useful as a nuclear fuel and a source of atomic or nuclear energy.

The first pure chemical compound of plutonium, free from carrier material and all other foreign matter, was isolated by B. B. Cunningham and L. B. Werner at the wartime Metallurgical laboratory in Chicago, Ill., during Aug. 1942. This isolation marks the first sight of a synthetic element and the first isolation of a weighable amount of an artificially produced isotope of any element.

Occurrence and Production.—Plutonium occurs in nature in uranium-containing ores in a very small concentration. Such plutonium was first discovered in Canadian pitchblende by G. T. Seaborg and M. L. Perlman in 1942. The isotope involved is Pu^{239} which is formed continuously as a result of the absorption of neutrons by U^{238} . The neutrons are those emitted during the spontaneous fission of uranium and those resulting from the action of alpha particles on the near-by light elements, and the concentration of Pu^{239} is determined by the equilibrium balance between its rate of formation and its rate of radioactive decay.

TABLE II—Concentrations of Plutonium in a Number of Ores

	$\text{Pu}^{239}/\text{ore}$
Pitchblendes	
Canada (23.5% U)	0.1×10^{-11}
Belgian Congo (48% U)	4.2×10^{-11}
Colorado (50% U)	3.8×10^{-11}
Monazites	
Brazil (5.24% U)	2.1×10^{-11}
North Carolina (1.64% U)	5.9×10^{-11}

By far the most important source of plutonium is that of its production or manufacture in nuclear reactors or chain reacting piles. An example is a nuclear reactor consisting of natural uranium and some neutron-slowing material or moderator such as carbon (graphite) or heavy water (deuterium oxide). In such a reactor a self-sustaining nuclear chain reaction results from the fission of the uranium isotope U^{235} with neutrons, and the excess neutrons are absorbed by U^{238} to form Pu^{239} which decays by two successive beta-particle emissions to Pu^{239} . After the production of the Pu^{239} , it is separated by chemical means from the highly radioactive fission products and the uranium and other foreign material. The chemical plants for this purpose are massive structures which are engineered to fit the grave problems inherent in handling the extremely high levels of radioactivity caused by the fission products. The manipulations in these plants are carried out entirely by remote control through heavy walls of shielding material.

Uses.—The main use for plutonium, in the form of isotope Pu^{239} , lies in its application for nuclear (or atomic) energy. Nuclear reactors may be built to use the isotope Pu^{239} as fuel. Such reactors, operating in conjunction with the abundant isotope of uranium, U^{238} , can generate energy through the "burning" of the Pu^{239} while they at the same time produce more Pu^{239} as a result of the absorption of neutrons in U^{238} , such a system is known as a "breeder." A fissionable isotope such as Pu^{239} gives rise to an amount of heat energy equivalent of about 20,000,000 kw-hr per pound when it completely undergoes the fission reaction. In industrial uses the energy may be used in this heat form or, in most cases, converted into the more convenient electrical form by more or less standard turbine equipment. The efficiency with which this heat energy can be turned into electrical power in an industrial nuclear energy reactor would depend on the details of the particular machine, but it seemed likely in the early 1950s that efficiencies of about 20% to 30% might be realized. The isotope Pu^{239} can also be used as an explosive ingredient for nuclear (atomic) weapons. An important use of the by-product radioactive tracers, which may be formed by neutron absorption in various chemical elements inserted into a chain reacting unit, is for fundamental and applied investigations in basic science, agriculture and industry and for fundamental investigations and therapeutic uses in biology and medicine.

Chemical Properties in Aqueous Solution.—The chemistry of plutonium is markedly similar to that of uranium and neptunium, the elements immediately preceding it in the periodic table. The differences in the chemical properties of these elements are due primarily to a progressive increase in the energy required to form their positive ions.

Plutonium exhibits four oxidation states in aqueous solution, +3, +4, +5 and +6. The ionic species corresponding to these oxidation states vary with the acidity of the solution. In moderately strong (one molar) acid the species are Pu^{3+} , Pu^{4+} , PuO_2^{2+} and PuO_4^{2-} . The ions are hydrated but it is not possible at present to assign a definite hydration to each ion. The potential scheme of the ions in one molar acid is the following

The potentials are in volts relative to the hydrogen-hydrogen ion couple as zero.

The potentials of the various couples are so nearly the same that the intermediate oxidation states are unstable with respect to self-oxidation and reduction

and,

These net changes do not indicate the mechanisms of the reactions, which are more complex. The disproportionation of PuO_2^{2+} is accompanied by a simultaneous oxidation of Pu^{3+} by Pu^{4+} (with the products PuO_4^{2-} and Pu^{3+} formed).

The oxidation-reduction relationships of the plutonium ions in acid solution are among the most intricate to be found in the field of inorganic chemistry.

The values given for the potential scheme in one molar acid may be altered extensively by a change in hydrogen ion concentration or, as a result of the addition of substances capable of forming complex ions, with the plutonium species. Among such substances are sulphate, phosphate, fluoride and oxalate ions, and various organic compounds, especially those known as chelating agents. The tetrapositive and hexapositive ions are complexed appreciably even by nitrate and chloride ions. The stability of the complex formed with a specified anion increases in the order: PuO_2^{2+} , Pu^{3+} , PuO_4^{2-} , Pu^{4+} .

The hydrolysis of the ions follows a similar order; Pu^{4+} begins to hydrolyse even in tenth molar acid and in hundredth molar acid forms partly the hydroxide $\text{Pu}(\text{OH})_3$ and partly a colloidal polymer of variable but approximate composition $\text{Pu}(\text{OH})_{3-4}\text{X}_2$, where X is an anion present in the solution. Further reduction of the acidity results in the hydrolysis of PuO_2^{2+} near pH 5, of Pu^{3+} at about pH 7, and of PuO_4^{2-} at about pH 9.

The potentials of the couples involving either of the two lower states with either of the two upper states have an approximately fourth power hydrogen ion concentration dependence in moderately acid solution. This dependence, together with the hydrolytic effects just mentioned, causes rapid alteration in the potential values with change in acidity. Approximate values for the potentials in a neutral solution are given in the following scheme

The plutonium ions in aqueous solution possess characteristic colours

for that oxidation state in solution. The most useful bands for this purpose are those at 9,000, 6,650, 6,030, 6,000 and 5,600 Å for Pu^{3+} , at 8,150, 7,500, 7,000, 6,650 and 4,700 Å for Pu^{4+} ; at 7,750 and 5,650 Å for PuO_2^{2+} and at 9,830, 9,530 and 8,330 Å for PuO_4^{2-} .

Absorption bands as sharp as those found in plutonium solutions are observed only in solutions of other actinide elements or of the rare earths. It is inferred that in plutonium, as in the rare earths, the bands originate from transitions occurring in protected inner f orbitals.

The aqueous ions of plutonium are strongly paramagnetic and measurements of the magnetism are in agreement with the assignment of five, four, three and two f electrons respectively for the oxidation states from +3 through +6.

Pure solutions of the upper and lower oxidation states may be obtained without difficulty, the former by oxidation with oxidizing agents such as bromate, dichromate or ozone, and the latter by treatment with reducing agents such as sulphur dioxide, hydroxylamine or hydrogen in the presence of platinum black. Because of the disproportionation reactions mentioned previously, the intermediate oxidation states are not stable. However, fairly pure solutions of Pu^{4+} may be obtained by dissolving the hydroxide in warm, concentrated perchloric acid, allowing several days at room temperature for reprecipitation and diluting the resulting solution. The disproportionation reaction is rather slow and the concentrations of Pu^{3+} and PuO_2^{2+} remain small for several hours.

The tetrapositive state is quite unstable in strongly acid solution, but becomes increasingly stable as the hydrogen ion concentration is decreased, down to about ten-thousandth molar. Dilute solutions containing a major proportion of plutonium as PuO_2^{2+} are stable at this acidity.

The precipitation properties of Pu^{3+} are similar to those of the tripositive rare earth ions, of Pu^{4+} to Ce^{4+} , and of PuO_2^{2+} to the corresponding ions of uranium and neptunium.

Tri- and tetrapositive plutonium ions form salts of low solubility with fluoride, oxalate, ferrihydride and hydroxide ions. The tetrapositive ion is precipitated also by iodate and arsenate, even in strongly acid solution.

Pentapositive plutonium may be precipitated as a potassium salt from strong carbonate solutions, but no other solid compounds of this oxidation state are known.

The plutonyl ion, PuO_2^{2+} , separates as the beautifully crystalline pink salt $\text{NaPuO}_2(\text{CH}_3\text{COO})_2$ from solutions containing a high concentration of sodium ions and acetate ions. This salt is analogous to sodium uranyl acetate and sodium neptunyl acetate.

Unlike many of the salts of uranyl uranium, the plutonyl salts are not fluorescent.

Nonaqueous Chemistry.—Many of the most important compounds of plutonium are formed by reactions between solid phases or solid and gas phases, rather than in aqueous mediums. The most interesting and important of these compounds are the oxides, the halides and oxyhalides and the binary compounds with carbon, nitrogen, silicon or sulphur.

TABLE III—Known Oxides of Plutonium

Composition	Colour and appearance	Crystal structure	Density (g./cc.)
Pu_2O_3 PuO_2 2:1.78	metallic lustre silvery, semimetallic	cube, NaCl type	13.89
PuO_2	greenish-yellow	II cubic, modification of rare earth sesquioxides cubic, CaF ₂ type	11.44

Oxides.—The plutonium oxygen system does not present the degree of complexity exhibited by the uranium oxygen system (see URANIUM) largely because of the stability of the dioxide. However, analogous behaviour is shown in the variable composition of the so-called sesquioxide ($\text{PuO}_{1.5-2.0}$). The monoxide had not been investigated with sufficient care in mid-century to determine whether it also exhibits variable composition.

Plutonium monoxide occasionally appears on the surface of metal exposed to atmospheric oxidation, but is prepared more conveniently by treating the oxychloride with barium vapour at about 1,250° C. The oxide is classified with the interstitial compounds rather than with the typical metal oxides.

The so-called sesquioxide ($\text{PuO}_{1.5-2.0}$) is a typical mixed oxidation state oxide, similar to those formed by uranium, praseodymium, terbium, titanium and many other metals. Its composition shows continuous variation with changes in temperature and pressure of oxygen above the oxide. The limits of composition given above are only approximate. Near the lower limit of the oxygen range the structure is hexagonal. A higher proportion of oxygen causes the oxide to assume the cubic C type modification of the rare earth sesquioxides. Plutonium sesquioxide may be formed by the thermal decomposition of the dioxide at about 1,500° C. in high vacuum.

Plutonium dioxide is the most important oxide of the element. Almost all compounds of plutonium are converted to the dioxide upon ignition in air at about 1,000° C. The ignited oxide is chemically inert at ordinary temperatures and has a well-defined composition. For these reasons it is a satisfactory compound for weighing in the gravimetric determination of plutonium.

The dioxide is frequently used as the starting material in the synthesis of other compounds of plutonium. In these cases prolonged high temperature ignition of the oxide is avoided, since this leads to progressive chemical inertness.

Plutonium dioxide was the first compound of the element to be isolated and weighed in pure form and it was in fact the first compound of any synthetic element to be separated in pure form in ponderable amounts. It was also the first compound of a synthetic element to be identified by X-ray diffraction methods (W. H. Zachariasen).

Halides and Oxyhalides.—All of the halides except the tri-iodide may be prepared by the hydrohalogenation of the dioxide or the oxalate of plutonium (III) at a temperature of about 700° C. With

hydrogen fluoride the reaction product is PuF_6 , unless hydrogen is added to the gas stream, in which case the trifluoride is produced. With hydrogen iodide the reaction product is PuOI , and the other oxyhalides may be formed by the addition of appropriate quantities of water vapour to the hydrogen halide gas. Plutonium tri-iodide is produced by the reaction of the metal with hydrogen iodide at about 400°C .

TABLE IV—Important Halides and Oxyhalides of Plutonium

Compound	Colour	Crystal structure	Density (g/cc)	M.P. ($^\circ\text{C}$)	B.P. ($^\circ\text{C}$)
PuF_3	violet	hexagonal, tysonite type	0.33	1,435	2,190*
PuF_4	light brown	monoclinic	7.0		
PuCl_3	emerald green	hexagonal, UCl_3 type	5.70	760	1,770*
PuBr_3	green	orthorhombic, PuBr_3 type	6.60	681	1,510*
PuI_3	bright green	orthorhombic, PuI_3 type	6.9	770*	1,380*
PuOCl	blue green	tetragonal, PuOCl type	8.81		
PuOBr	deep green	tetragonal, PuOBr type	9.07		
PuOI	green	tetragonal, PuOI type	9.46		

*Estimated value

retractory character and stability at high temperatures. These include the carbide, nitride, silicide and sulphide of the element.

TABLE V—Properties of Binary Compounds of Plutonium

Compound	Colour and appearance	Crystal structure	Density (g/cc)	Approx. temp. limit for stability in high vacuum ($^\circ\text{C}$)
PuC	black, semimetallic	cubic, rock salt type	13.99	1,800
PuN	brown	cubic, rock salt type	14.22	1,500
PuSi	silvery, metallic	tetragonal, PuSi type	9.12	1,000
$\text{PuSi}_{1.25}$	black	cubic, CeSi type	8.41	1,200

The monocarbide is formed by reacting the dioxide in intimate

contact. In 1412 the inhabitants petitioned for a charter, which was granted Nov. 12, 1439, the town being the first in England to be incorporated by act of parliament. In the discovery of the new world it played an important part. Sir John Hawkins was port admiral and (in 1571) M.P. From Plymouth in 1577 Drake set out on his voyage round the world, in 1581 he became mayor and represented the borough in parliament during 1592-93. Sir Humphrey Gilbert (M.P. 1571) sailed on his second colonizing expedition to America in 1583 from the port. Plymouth supplied seven ships against the Armada, and it was in the sound that the English fleet awaited the Spaniards. A stone on a quay at the Barbican records the fact that this was the last port touched by the Pilgrim Fathers on their voyage to America. During the Civil War the town withstood all efforts by the Royalists to take it, and it early declared for William of Orange. Plymouth was created a city in 1928 and the title of lord mayor was granted in 1935. Four years later its area was extended by almost 4,000 ac.

It lies at the head of Plymouth sound, stretching westward from the river Plym toward the mouth of the Tamar, from which it is separated by the township of East Stonehouse and the borough of Devonport, both of which were included in Plymouth in 1914. The water frontage of the "Three Towns" consists of Plymouth sound, with its inlets. The Cattewater and Hamoaze are flanked on the east and west respectively by high ground, on which are built forts. On the western side of the entrance to Cattewater is the Citadel, founded in the reign of Henry VIII and rebuilt by Charles II. It is a specimen of 17th-century military architecture, an irregular bastioned pentagon in trace and during World War II was used as army headquarters and barracks. The adjacent Hoe extends along the northern edge of the sound. To the north is seen the town of Plymouth. In the sound is Drake's (formerly St. Nicholas's) island. The city suffered air raids during World War II, and much of it was destroyed. More than 50,000 houses and buildings had been damaged before the close of 1941. Among churches, St. Andrews, a Perpendicular building of 1480-1520 restored in 1874, was destroyed, only the walls and clock tower remaining.

Plymouth is the seat of a Roman Catholic bishopric founded in 1851, the cathedral, in Wyndham street, being completed in 1858. The building is in the Early English style, and adjoining are the bishop's house and the convent of Notre Dame.

The port of Plymouth in 1311 embraced Plympton, Modbury and Newton Ferrers, and received a customs grant from Richard II. In 1435, 65 cargoes were imported, and in the reign of Elizabeth I it rose to be the foremost port in England. The 18th century saw a great development of trade with Virginia and the West Indies, and this resulted in the establishment of a sugar-refining industry that was maintained into the 20th century.

In 1749 the "town's water" was carried to the Barbican to supply shipping. The port of Plymouth as at present constituted embraces the waters of the Plymouth sound and the Hamoaze. The chief water area within the limits of the port is the sound with its inlets, the Cattewater, Sutton pool, Mill bay, Stonehouse pool and the Hamoaze. The sound itself covers an area of 4,500 ac. and is sheltered from the southwest gales by a breakwater a mile long with a lighthouse at its eastern end. It was constructed in 1841. Cattewater, Sutton pool and Mill bay constitute the three mercantile harbours of Cattewater harbour, Sutton harbour and the Great Western docks, while Hamoaze was set aside for the royal navy. Cattewater harbour has an area of 260 ac. and 8,000 ft. of quayage space. Sutton harbour entered from Cattewater has a quayage space of 4,500 ft. Great Western docks at Mill bay has an outer basin of 35 ac., an inner one of 13.

Steamers sail regularly from Plymouth for Australia, New Zealand, the Cape and North America. The port has productive fisheries. It has also a considerable export and import trade. As a naval station it is second only to Portsmouth. The city is served by the Western Region railway.

The industries of Plymouth include soapmaking, manufacture of chemicals, artificial manure and paper staining. There is some electrical engineering and a clothing factory. Plymouth has returned three members to parliament, from the Drake, Devon-

sulphide at 900°C .

Only the most important compounds of plutonium have been mentioned in this article. The number of known compounds is very large. (See also ATOMIC ENERGY; DEUTERIUM; ISOTOPES; RADIOACTIVITY; ARTIFICIAL.)

BIBLIOGRAPHY.—G. T. Seaborg, J. J. Katz and W. M. Manning (eds.), *The Transuranium Elements: Research Papers, parts I and II*, in "National Nuclear Energy Series," Plutonium Project Record, vol. 14b (1949).

PLUTUS, properly, the abundant increase of the earth, child of Demeter (*g v*) and Iasion, in art, usually shown as a child, alone or in company with Tyche, Eirene, Athena or some other goddess. In popular thought, allegories and comedy, he was represented as Wealth. He was said to be blind.

PLYMOUTH, a city, county borough and seaport of Devonshire, England, 231 mi. W.S.W. of London. Pop. (1951) 208,985. Area 20.5 sq.mi.

Plymouth, the Suttun of Domesday, was afterward divided into the town of Sutton Prior, the hamlet of Sutton Valletot and the tithing of Sutton Ralph. The market, established about 1253, became town property in 1311. In 1292 the town first returned members to parliament. In the 14th century it was often used for armaments to and from France and it suffered from French at-

port and Sutton divisions, since 1918

Lady Astor, the first woman elected to the house of commons, was returned in 1919

PLYMOUTH, a town of Massachusetts, U.S., 37 mi S.E. of Boston, on Plymouth Bay, a port of entry and the county seat of Plymouth county. It is served by the New York, New Haven and Hartford railroad and in summer by buses from Boston. Pop. (1950) 13,608 and in 1940 it was 13,100. Visitors to the number of many thousands are brought annually by the historic interest of the town and its attractions as a summer resort. The modern town has important manufacturing industries (notably the largest cordage works in the world, with its own steamers bringing cargoes of sisal fibre from Yucatan). Plymouth has two large woollen mills. Other important industries are cranberry culture, herring fisheries, curtain manufacturing, boat building and repairing and zinc and tack manufacturing. Lobster fishing is also an important industry.

Plymouth was the landing place of the Pilgrims and the first permanent settlement by Europeans in New England. Plymouth Rock, the granite boulder on which the Pilgrims stepped from the shallop of the "Mayflower" on Dec. 31, 1620, was placed in 1920 on the spot it originally occupied, under a protecting portico of granite, presented by the Society of Colonial Dames, and this part of the water front has been made a part of the state park system. Rising behind the Rock is Cole's hill, where during their terrible first winter in America the Pilgrims burned half their number, leveling the graves and sowing them with grain in the spring to conceal their losses from the Indians. Burial hill (the site of the first fort and of a watchtower) contains the graves of William Bradford and others of the original Pilgrims, though the oldest stone is dated 1681. In the Registry building are the original records of Plymouth Colony, the will of Miles Standish, the original patent of Jan. 23, 1630, and many other interesting historical documents. Pilgrim hall, a large stone building erected in 1824, houses a rich collection of relics of the Pilgrims and of early colonial times. The oldest house still standing (the Crowe house) was built in 1664, and many others antedate the Revolution. In the northern part of the town is the National Monument to the Forefathers (of Maine granite), designed by Hammett Billings, which was dedicated on Aug. 1, 1889, 30 years after the cornerstone was laid. Plymouth dates its founding from the landing of the Pilgrims. It was never incorporated as a town, but in 1633 the general court of the Colony recognized it as such by ordering that "the chiefe government be tyed to the towne of Plymouth."

It remained the seat of government until 1692, when Plymouth Colony was united to Massachusetts Bay Colony.

PLYMOUTH, a borough of Luzerne county, Pennsylvania, U.S., on the west bank of the Susquehanna river, opposite Wilkes-Barre. It is on federal highway 11 and is served by the Lackawanna and the Delaware and Hudson railways. Pop. (1950) 13,021, 1940 federal census 15,507. Plymouth is in the midst of the anthracite fields, and is surrounded by the beautiful scenery of the Wyoming valley. The mining, preparation and handling of anthracite provide the principal occupations, but there are various other industries. Plymouth was settled in 1769 under the auspices of the Susquehanna Company of Connecticut, by colonists from Plymouth, Litchfield county, Conn., and other places in New England, and became a centre of the conflict known as the Pennamite-Yankee war. (See WYOMING VALLEY.) The first coal shipped from the anthracite region was sent from Plymouth in 1808 by Abijah and John Smith. The borough was incorporated in 1866.

PLYMOUTH BRETHREN, a community of Christians who received the name in 1830 when Rev. J. N. Darby (1800-1882) induced many of the inhabitants of Plymouth, Eng., to associate themselves with him for the promulgation of his opinions.

Although small Christian communities existed in Ireland and elsewhere calling themselves Brethren, and holding similar views, the accession to their ranks of Darby so increased their numbers and influence that he is usually called the founder of Plymouthism.

Darby had been a curate in Wicklow 1825-27, when he felt himself constrained to leave the Anglican communion; going to Dublin, he became associated with several devoted people who called themselves Brethren. Among these were A. N. Groves and J. G. Bellett, who rank among the founders of the movement. In 1830 Darby at Plymouth won over many people to his way of thinking, among them the well-known biblical scholar Samuel Pearsall Tregelles. During the next eight years progress was rapid, and communities were founded in many towns of England.

In 1838 Darby went to reside in French Switzerland and made many disciples. French Switzerland remained the stronghold of Plymouthism on the continent, and for his followers there Darby wrote two tracts, *Le Ministre considéré dans sa nature* and *De la Présence et de l'action du S. Esprit dans l'église*. The revolution in the canton Vaud brought persecution to the brethren in the canton and in other parts of French Switzerland.

He returned to England, and his reappearance was followed by divisions among the Brethren at home. These divisions began at Plymouth. Benjamin Wills Newton, head of the community there, who had been a fellow of Exeter college, Oxford, was accused of departing from the testimony of the Brethren by reintroducing the spirit of clericalism. Unable to detach the congregation from the teacher, Darby began a rival assembly. The majority of the Brethren out of Plymouth supported Darby, but a minority remained with Newton. The separation became wider in 1847 on the discovery of supposed heretical teaching by Newton. In 1848 another division took place. The Bethesda congregation at Bristol, where George Muller was the most influential member, received into communion several of Newton's followers and justified their action. Out of this came the separation into Neutral Brethren, led by Müller, and Exclusive Brethren, or Darbyites, who refused to hold communion with the followers of Newton or Muller. The Exclusives, who were the more numerous, suffered further divisions. An Irish clergyman named Samuel O'Malley Cluff had adopted views similar to those of Pearsall Smith, who preached a doctrine of sanctification called "Death to Nature" as an antidote to the supposed prevalent Laodiceanism, and when these were repudiated seceded with his followers. The most important division among the Exclusives came to a crisis in 1881, when William Kelly and Darby became the recognized leaders of two sections who separated on a point of discipline. This was followed (1885) by the disruption of the strict Darbyite section, two communions being formed out of it upon points of doctrine.

The theological views of the Brethren differ considerably from those held by evangelical Protestants. They make the baptism of infants an open question and celebrate the Lord's Supper weekly. Their distinctive doctrines are ecclesiastical. They hold that all official ministry, whether on Episcopalian, Presbyterian or Congregationalist theories, is a denial of the spiritual priesthood of all believers, and sets aside the Holy Spirit's guidance.

See W. B. Neathy, *A History of the Plymouth Brethren*, and ed (London, 1902).

PLYMPTON ST. MARY AND PLYMPTON ST. MAURICE or **EXETER**, two small adjacent towns in Devon, England, 5 mi E.N.E. of Plymouth, on the Western Region railway route. Pop. (1931), Plympton St. Mary, 5,077, Plympton St. Maurice, 1,075. The earthworks on which in the 12th century Richard de Redvers reared his Norman castle at Plympton St. Maurice were probably of British origin, traces of the castle remain. A Saxon document dated 904 records a grant by Edward the Elder to Asser, bishop of Sherborne, of 12 manors in exchange for the monastery of Plympton. Plympton St. Mary has a Decorated and Perpendicular church, with a lofty tower of the later period. Near it are remains of the former Augustinian priory of Plympton, founded by William Warelwast, bishop of Exeter (1107-36). They include an Early English refectory with Norman undercroft, the kitchen and other fragments, but there are no remains of the great priory church. There are several old houses in the town, together with a guildhall dated 1696, and a grammar school founded in 1658, of which Sir Joshua Reynolds' father was master.

PLYNYLIMON (*Plynlimmon, Pumplimon, Pumlimon, Penlimon*: *pump* means fire; *limon*, chimney flag or beacon; *pen*, head), a mountain of Wales 2,463 ft high, about 10 m. from Machynlleth and Llandilo. It is composed of Bala (Ordovician) grits and stands out above the high plateau of Central Wales. There are three summits with a *carnead* (stone-pile, probably a military or other landmark, rather than the legendary barrow or tomb) on each. Plynlimon is the source of the Rheiddol, the Llyfiant and the Clywedog, the Wye and the Severn.

The morasses of Plynlimon saw many a struggle, notably the war between Owen Cyfeiliog (β c. 900), prince of Powys, and Hywel ab Cadogan. Here also Owen Glendower unfurled the banner of Welsh independence; from here, in 1401, he harassed the country, sacking Montgomery, burning Welshpool, and destroying Abbey Cwm Hir. Aberystwyth obtains its water from a reservoir on the mountain slopes. There are slate quarries, also old lead and copper mines in the district. The district west, north and east of Plynlimon is a very wild and lonely moorland, with very few roads. Around the sharp northern and western edges of the moorland are deep-cut ravines with waterfalls.

PLYWOOD. Board made of several plies or veneers (*qv*) of wood, glued together with the object of obtaining comparatively large sheets free from some of the natural defects and limitations of timber. *Rotary cut* (peeled) or *liced* veneers are used, if necessary joined edgewise, to form each ply, and thus large sheets with an unbroken surface are obtained, the plies are sorted as to their appearance, and the inferior (knotty, shaky or sappy) material is generally utilized for the interior of the board (*core*), leaving the best plies for the outer surfaces (*face and back*).

The natural tendency of wood to shrink, swell and warp is effectively neutralized, and the comparatively low tensile strength of wood along its grain is greatly improved upon, by carefully cross-graining the plies. In the result, a large flat board of wood is produced, practically unaffected by climatic influences, and possessing considerably higher shearing, braking and bending properties than ordinary wood of similar thickness.

The plies are glued (*cemented*) together under considerable pressure, different adhesives being used, dependent upon whether or not the gluing process is aided by heat, and also varying according to the kind of timber used. The veneers are wet when produced from the log and may be glued together either in their wet state or after a pre-drying process. Plywood is, therefore, grouped into two classes, *wet* and *dry* produce. The drying of veneers before being cemented and pressed into a board prevents their shrinkage during the pressing process and, therefore, helps to make a better plywood board. If the veneers be glued wet the drying process is combined with the gluing operation in the press, and this often produces face checks (cracks) on the surfaces of the finished board.

In the construction of plywood the different types are shown in the drawing.

The outside plies of the laminated type and of batten boards may be occasionally superimposed on so-called crossbandings (veneers lying crosswise to the outer plies) to ensure still greater rigidity of the boards.

Utilization.—Plywood is used wherever a material is required to cover large unbroken spaces with a light but strong and rigid sheeting, e.g., in *cabinet-making* (for panels, bed-ends, sides of wardrobes, tabletops, etc.), *building* (for doors, wall panelling, ceilings, flooring, etc.); *coach-building* (for coach panels, motor bodies, railway carriage roofs and walls, vans, baby carriages, etc.); *shipbuilding* (for bulkheads, etc.), *boxmaking* (for tea chests, rubber chests, cases, etc.); *engineering* (for aeroplane

fuselages, hydroplane hulls, bed plates, etc.), etc.

Although there is evidence that the principle of "plying" thin strips of wood into panels to ensure permanent flatness was known and practised in very early days of civilization and was continued by the cabinet-maker and builder all over the world, mechanical production of plywood originated comparatively recently, i.e., in the eighteen-eighties, when the first factories specializing in the production of plywood were erected in Russia. The industry has since spread to all parts of the world wherever large timber resources are available and where widespread employment of the material makes local manufacture profitable.

PNEUMATIC CONVEYING is the utilization of the conveying power of air in motion. It will be realized that conveyance of material through a pipe-line, either by suction or

blast, is ideal, since there are no mechanical parts in the path of the material there cannot be any contamination by lubrication. Another advantage is the greater flexibility of pneumatic plant; every part of the hold of a vessel, for instance, can be reached by flexible tubes for the purpose of unloading a grain cargo, whereas a more complex mechanical plant is rigidly fettered to straight lines.

The *modus operandi* of a pneumatic plant is extremely simple and is as follows.—Into a grain cargo in a vessel, for instance, a

hosepipe is lowered, the nozzle at the end of which admits a mixture of air and grain. The other end of the pipeline enters tangentially into the upper part of a cylindrical receiver from which the air is exhausted, while the grain is withdrawn from the cone-shaped lower end by an air-trap, without, however, admitting air into the receiver. When comparing pneumatic with mechanical handling devices the former have but one drawback, viz., the greater consumption of driving power for handling a given quantity. This, however, is more than compensated for by the greater flexibility and the hygienic value of the system. The first grain handling installation on the Duckham system was known as "Mark Lane No. 1," and was built, under the personal supervision of the inventor, by the East Ferry Road Engineering Co., during the closing years of the 19th century. This was one of the most epoch-making revelations of all systems of handling. The plant is mounted on a pontoon and sucks the grain through a nozzle and pipeline from the ship's hold to an elevated receiver, whence it runs by gravity to a given point, via an air trap, an exhaustor furnishes a partial vacuum by pipes connected with the said receiver.

As has been shown, the material in a pneumatic plant floats, so to speak, in a current of air, from which it is separated by its specific gravity when the air expands in the receiver. The heavier the material to be handled the greater must be the speed of travel of the air in the conveying pipes in order to ensure the floating of the material in and with the air. If the air speed is too slow the tendency will be for the material to separate from the air and thus block the pipes, especially such portions as are horizontally disposed, or nearly so. Obviously, therefore, installations for such heavy materials as coal and ash require more powerful pumps. Similar installations in which, however, draught is induced by "steam jets" are successfully employed for handling ash from boilers.

Owing to the advantages accruing from the use of pneumatic handling plants new avenues for their employment are being constantly opened. Such varied materials as grain, small coal,

PLYWOOD CONSTRUCTION
(1) Ordinary plywood, (2) laminated plywood, (3) batten board

chemicals, ashes, potatoes, and even red-hot rivets and artillery shells are now successfully handled by pneumatic means. An offshoot of this system is the pneumatic tube, which is largely employed in postal and telegraph offices, as well as in great variety in business offices and stores (G F Z)

PNEUMATIC DISPATCH, a system of transporting written dispatches through long tubes of small diameter by means of compressed or rarefied air. It was introduced in 1853 by J. Latimer Clark between the Central and Stock Exchange stations of the Electric and International Telegraph company in London, the stations being connected by a tube 1½ in diameter and 220 yd long, the messages, enclosed in a tight fitting carrier, being drawn through it by the production of a partial vacuum at one end. The system was improved in 1858 by C. F. Varley, who used compressed air to return the carriers in the other direction. By this means it was possible to develop two-way working on single tubes and between a central station, equipped with air-compressing plant, and outlying offices.

Pneumatic dispatch tubes are in extensive use in many countries for both telegraphic and postal matter.

Radial System: This system of pneumatic dispatch was developed by R. S. Culley and R. Sabine in connection with the British post office for the transmission of telegrams between local collection and delivery offices and the central telegraph office, it became generally more economical, under normal conditions of traffic and distance, to transmit these messages by tube rather than wire so dispensing with the employment of skilled telegraphists.

Since that time the system has been greatly extended both in London and the large provincial towns until in London alone the street tubes laid measure over 57 m, varying in length from 100 yd to nearly 4,000 yd. These tubes are either single tubes working in both directions or, where the traffic warrants it, separate "up" and "down" tubes are installed. In a few cases intermediate offices are connected to the tubes, but this practice is not desirable as delay in transmission is caused and direct tubes are installed wherever possible.

A further development is the laying of pressure worked trunk tubes from the central telegraph office to an outlying centre, messages being transmitted between this centre, where a pumping plant is also installed, by radial tubes to offices in the vicinity.

House Tubes and Street Tubes.—Short tubes known as house tubes are in use in a large number of offices and telephone exchanges for carrying messages from the public counter or one room to another. These tubes, which are generally 1½ in diameter, are made of brass and are operated by hand-worked pumps where the distance is short and the traffic inconsiderable, or by means of small electrically driven centrifugal fans or other form of blower. The pressure or vacuum required is only a few inches as shown by water gauge and the blowers are either run continuously or switched on as required.

Street tubes used by the post office are generally 2½ in diameter, but 3 in and 1½ in tubes are also used. These tubes when laid in the street are in all cases made of lead and are protected by cast-iron pipes. Where they are run in buildings or subways brass tubing is used. They are operated by electrically driven compressors.

Carriers.—The carriers, in which the messages are inserted for dispatch, are made of gutta-percha covered with felt, the front of the carrier being provided with a buffer or head formed by several layers of felt fitting the tube closely, the messages being held in place by means of an elastic band. The 3 in carriers hold 50, the 2½ in carriers 20 and the 1½ in carriers five ordinary forms. The carrier used on house tube systems are generally made of fibre the messages being retained by a clip.

Working.—The air for working the street tubes is supplied by electrically driven compressors, the standard pressure and vacuum used being 10 lb and 6½ lb. per sq in respectively, which values give approximately the same speed.

The time of transit of a carrier through a tube at the ordinary pressures in use is given approximately by the empirical formula:—

$$t = 0.0872 \sqrt{\frac{P}{P-d}} \text{ where } t = \text{length of tube in yards,}$$

d = diam in inches, P = effective air pressure in pounds per sq inch,

t = transit time in seconds.

For vacuum working the formula is:—

$$t = \frac{0.0825}{1 - 2.34 \sqrt{15.5 - P_1}} \sqrt{\frac{P_1}{d}} \text{ where } P_1 = \text{effective vacuum in lb per sq. inch.}$$

The horse-power required to propel the carrier is approximately

$$\text{for pressure H.P.} = (574 + 0.011 P) \sqrt{\frac{P^3 d^5}{l}}$$

$$\text{for vacuum H.P.} = (5.187 - 1.214 \sqrt{15.5 - P_1}) P_1 \sqrt{\frac{P_1^3 d^5}{l}}$$

For a given transit time the horse-power required is less in the case of vacuum than in the case of pressure working, owing to the lesser density of the air column moved, thus, for example, the transit time under 10 lb pressure is the same as with a vacuum of 6½ lb, but the horse-power required is as 1.83 to 1. A 2½ in tube 1 m long worked at 10 lb per sq in pressure will have a transit time of 2½ min and will theoretically require 3.35 hp to work it. Actually owing to various losses 25% more power must be allowed for the compressor. When working at the same pressure the transit time for a 2½ in tube is 16% more than that for a corresponding length of 3 in. tube, but the power required is 50% less and it is therefore advisable to use the smallest tube compatible with the traffic.

Dispatching and Receiving Apparatus.—On house tube systems, where only low pressures and vacuum are required, simple forms of terminals consisting of cast-iron bodies with flap-doors are used, the doors being opened to insert a carrier, and through which carriers are automatically ejected, the door closing behind them. Dispatching funnels are also used at the open end of tubes.

On the street tubes, however, a more complicated type of apparatus, called a double slide switch, is used at the central office. This consists of two vertical sections of tube secured into top and bottom plates and provided with a handle by which it is rocked between two fixed horizontal plates forming a frame, three holes being provided in each plate, the air supply pipe and dispatch tube being connected to the centre holes and funnels for inserting or removing the carriers to the other holes. The carrier on arriving is received in one of the vertical sections and on the rocker being moved to its second position the carrier drops out through the funnel provided. The second tubular section is now ready to receive a carrier, which is discharged when the rocker is returned to its first position. The process is reversed for dispatching purposes, and where the tube is used for two-way working one position is reserved for sending and one for receiving. The supply of air, and whether under pressure or vacuum for sending or receiving purposes, is controlled by a three-way valve mounted under the switch.

A form of flap terminal, the door being restrained by a spring in view of the higher pressures used, is installed at the outlying offices in place of the receiver originally used and the carrier is automatically ejected.

On tubes where the carrier reaches a high velocity, a by-pass is provided near the terminal by means of which the air pressure behind the carrier is released after it has passed this point so as to reduce the velocity of egress. This terminal is also used for the dispatch of carriers to the central office, the supply of air to the tube being changed from vacuum to pressure at the latter point in response to a bell signal. When used for dispatching the by-pass is cut off by a remote control valve. Carriers may be diverted from one tube to another by means of a moving section of tube directly or remotely controlled.

A further development is the provision of an automatic rotat-

ing pneumatic tube switch by which carriers can be transferred between street and house tubes for both sending and receiving purposes, the terminals used being of the flap type.

Circuit System—Another system of working is the circuit system, in which stations travel in one direction only, both pressure and vacuum being used. This system is in use in Paris and other Continental cities. In Messrs Siemens' system a continuous flow of air is maintained in the tube, the carriers being dispatched or removed through a form of rocking switch so designed that the movement of carriers in other parts of the system is not interfered with. More usually carriers, or trains of carriers, are dispatched at intervals, the air supply being cut off when not required. Long tubes may be sectionalized, means being provided at the various stations by which air is only supplied to the working section.

In America, under the Batcheller system, tubes 8 in. in diameter are used for postal purposes in New York, Brooklyn, Chicago, Philadelphia, Boston and St. Louis, tubes 6 in. and 10 in. in diameter are also used. These tubes are essentially cast-iron pipes, carefully bored and equipped with suitable apparatus for introducing and receiving the carriers. The carriers for the 8 in. tubes consist of cylindrical steel shells about 7 in. in diameter and 2 1/2 in. long (inside dimensions) with suitable end covers. They are fitted with lubricated soft bearing or packing rings. The working capacity of these tubes may be taken as 8 lb. per container and six containers per minute, or 2,880 lb. of postal matter per hour in each direction, the average speed being about 25 to 30 m. per hour.

The dispatching apparatus is similar to that in the Siemens' system, consisting of two sections of tube supported in a rocking frame so arranged that either section may be brought into line with the main tube, in which a current of air is constantly flowing. One of these sections maintains the continuity of the tube while the other section is loaded. The switch is then swung over by means of a pneumatically operated piston to insert the carrier in the tube. A by-pass is provided to maintain the flow of air in the tube during the operation. As soon as the carrier leaves the switch it trips a lever and the switch automatically returns to the loading position. A time lock is used to prevent carriers being dispatched too frequently. The carrier is received by an air cushion formed by closing the end of the tube with a sluice gate, a by-pass being provided before this point to allow the air to flow away.

In addition to their use for postal and telegraphic purposes pneumatic dispatch tubes are used for internal communication in offices, hotels, etc., also in shops for the transport of money and bills between the counters and the cashiers' desk. Pneumatic tubes are also used for the unloading and transport of grain and other commodities in bulk between warehouses and ships, trains, etc.

BIBLIOGRAPHY—The system as developed for use in the British post office by Messrs. Culley and Sabine is described in a paper in *Min. Proc. Inst. Civil Eng.*, vol. xliii. The same volume contains a description of the Paris system and of experiments thereon by M. Bontemps, and also a discussion of the theory of pneumatic transmission by Prof. W. C. Unwin. Reference should also be made to a paper by C. Siemens (*Min. Proc. Inst. Civil Eng.*, vol. xxxii), describing the Siemens' circuit system, to *Les Télégraphes*, by M. A. L. Ternant (1881); to the report to Congress of the American joint commission on pneumatic tube mail service, March 1919, General Post Office engineering department's *Technical Instruction No. X* (Pneumatic Tubes), a short paper by J. McGregor on the automatic system in the post office (*P.O. Elec. Eng. Journal*, vol. xix, part 1), and to Kemp's *Engineer's Year Book* (J. McG.).

PNEUMATIC TOOLS comprise various classes of hand tools which are operated by compressed air power. They are divided in two general classes according to the principle of operation (1) percussion, (2) reciprocating motor-driven. Under percussion tools are grouped rivetting, chipping and sand rammers, pneumatic diggers, rock drills, paving breakers, etc.; each using a piston or plunger for striking a blow. Reciprocating motor-driven tools employ a reciprocating piston air motor to drive a spindle from which power can be used for drilling, grinding, etc. The tools under this classification include pneumatic drills, grinders, motors,

hoists, etc. Pneumatic tools usually operate best when supplied with compressed air at 90 lb. gauge pressure.

The principal uses of pneumatic tools occur on those classes of work where it is not possible or not advisable to take the work to a machine. A pneumatic tool, being a self-contained power unit, can be taken to the work and various operations performed rapidly, with a minimum of manual labour. Pneumatically operated tools are suited for a wide variety of uses because of their availability, the adaptability of compressed air power, the absence of danger and because they embody within small confines a great range of power and action. Other advantages are rugged construction, simplicity, and easy operation.

Pneumatic Hammers are made in a variety of sizes and types, and the name for each is governed largely by the work to be performed. This group covers chipping, rivetting, scaling and caulking hammers, diggers, paving breakers, rock drills and similar implements. (See **BLASTING**.) Each class of work requires a hammer of a particular size, weight, speed and strength of blow. In the operation of most rivetting hammers air enters the hammer at the air inlet in the handle, the amount of air being controlled by the throttle valve which is actuated by a trigger. After passing the throttle valve the air is conducted through the passage in the handle to the valve chamber containing the operating valve and valve box. The valve is moved back and forth in the valve box by the action of the air pressure on its differential areas. As the valve moves forward it admits air back of the piston, throwing it forward against the rivet set, which forms the rivet head. The piston, after striking a blow, is returned for another stroke by air admitted to the front of the cylinder, which is covered by the piston in this position. Hammers for chipping, caulking and scaling are very similar in construction to the rivetting hammer. The chipping hammer is used to clean foundry castings, for caulking the seams of boilers and tanks, pipe joints, etc., saving two-thirds the time required by hand work.

Sand Rammers have a long barrel containing a piston having a projecting rod at one end, to which the tamping butt is attached. In action the piston moves rapidly up and down in the barrel lifting the tamping butt from the sand and returning it with considerable impact against the material to be rammed. The ramming of certain classes of moulds in foundry work, a long and arduous task when done by hand, is rapidly accomplished by means of the pneumatic sand rammer. Machine-rammed moulds are harder and more uniform than those rammed by hand, resulting in better castings. Floor rammers are used for working on large moulds on the floor, and the bench rammer on small bench moulds. These tools strike up to 800 blows per minute. The force and number of blows are regulated by the operator with a throttle. The sand rammer is also used to tamp the back-fill in trenches in city streets, where it is desired to pack the sand solidly and by this means avoid the subsequent settling.

Pneumatic Drills—Portable pneumatic drills are divided into four general types: the reversible drill, the nonreversible drill, the woodborer and the close-quarter drill. The several types are also given certain other minor divisions according to the use to which they are put, such as boring, reaming, tapping, flue rolling and stud-setting. The larger sizes of pneumatic drills use a four-cylinder V-type air motor, with one crank throw provided for each pair of cylinders in the same cross plane. The power from the crankshaft is transmitted to the drilling spindle by gears arranged to give the spindle speed desired. A feed screw with a feed handle is used to feed the drill up to the work. A main valve, of rotary type, controls the supply of air to each of the four cylinders, the air supply reaching this main valve through a throttle handle. At the upper end of the main valve is located a centrifugal speed governor which limits the speed of the drill motor after it has passed the point of maximum horsepower.

Another small class of pneumatic drills employ a three-cylinder radial air motor, the three cylinders being in one plane with one crank provided for all three cylinders. The power from the crank is transmitted through a spindle and gears to the point

where the drill chuck is attached. The main spindle also serves as a valve controlling the air to the three cylinders, greatly simplifying the construction of the tool. These tools are used for light drilling in metal, in the automobile assembly plants for running up nuts, and for running in screws. They are equipped with either feed screw, spade handle or breast plate. The close-quarter type of pneumatic drill uses a two-cylinder, double-acting motor to give a flat and compact construction. The power is transmitted from the crankshaft to the spindle by a train of gears. A feed screw is located at the end of the spindle and can be turned by means of the ratchet handle. This type of drill is used for drilling, reaming and tapping in cramped spaces where the usual drill cannot be employed.

Pneumatic Grinders.—The pneumatic grinder is similar in general construction to the air drill except that a higher speed motor, operating at 3,000 to 6,000 r.p.m. is used. The motor is directly connected to a spindle upon which is mounted the grinding wheel. These tools are used in all kinds of service where a portable grinding tool, buffer or polisher is needed and are widely used in foundries and machine shops, monumental stone shops and automobile body plants.

Pneumatic Diggers.—Pneumatic diggers, of the same operating principle as a rivetter, are made in two styles. A short-handle type is used in tunnel work or in close quarters and an extension-handle type for trench or shaft. Pneumatic diggers are a recent development for work where it is desired to replace the hand pick. The tools are used for loosening up clay, hard ground, etc. The pneumatic digger consists of a hammer having a piston which strikes against a blade or scoop. The blows of the piston drive the blade into the ground, prying it loose. One man with such a tool is the equal of six men using ordinary hand picks.

Rock Drills.—The removal of solid rock in excavation for foundations, trenches, highways, in mining and many other projects calls for the use of a vast number of compressed-air rock drills. These tools are made in a wide variety of sizes for all classes of work, depending on the size and depth of the hole to be drilled, the hardness of the rock and other factors. In the jackhammer type of rock drill, compressed air enters to a throttle valve in the handle and then passes to a flapper type of plate valve, which controls the movement of the piston. On the forward or downward movement of the piston it strikes against the shank of the drill steel, and imparts a cutting action to the points of the steel. On the back stroke of the piston it slides over a fluted rifle bar which turns the piston and causes it to turn the drill steel. Rotation of the drill steel is desired in order that the cutting edges on the end of the drill steel may be put in a new position with regard to the rock being drilled. A ratchet mechanism ensures rotation in one direction. To blow out the cuttings and dust from the hole in the rock, air is passed down through the rifle bar and piston and through the drill steel to the cutting face.

These tools make it possible to drill holes in rock for inserting the explosives which blast out rock. One rock drill bores 100 to 150 ft of hole in rock in an eight-hour day, while the best a man can do using a hand hammer and steel is not more than 8 to 10 ft a day. Rock drilling requires the use of pointed drill steels which must be resharpened as the cutting edges become worn and dulled by the rock. This is done by compressed-air-operated drill steel sharpening machines in which after the drill steel is heated and inserted quickly shapes and sharpens the steel by means of dies many times faster than by hand methods.

Paving Breakers.—The paving breaker is a tool somewhat similar in construction to the rock drill and is used in demolition work such as breaking up pavement, tearing out concrete walls, foundations, etc. This tool uses a pointed chisel or steel, but it is not rotated. The absence of the rotation mechanism simplifies the general construction of the paving breaker. Paving breakers are extensively used by public utilities for making openings in the pavement prior to installing or repairing sewer pipes and connections. They are usually operated from a portable air compressor, mounted on a motor truck, which can be quickly taken to the place where the work is to be done. One man

operating one tool is able to break out more pavement in a given time than 12 to 15 men using hand sledges and steels.

Air Motor Hoists.—These are made in a range of sizes to handle loads from 500 lb up to 20,000 lb. This style of hoist is equipped with a high-powered air motor of the four-cylinder type which is geared to a hoisting drum. A feature of these hoists is the automatic brake which acts to hold the load at any point after the air pressure is shut off. When the motor is operating, air passes to the brake through a connecting tube releasing it. When the air is shut off at the throttle, the brake is automatically applied. These air hoists are widely used in industrial plants for handling material too heavy to be easily lifted by one man. In machine shops they lift and place heavy parts on lathes, milling machines and planers. (See MECHANICAL HANDLING.) Air hoists are particularly suited for foundry work because the operation is not affected by dust, dirt or fumes, and they are not damaged by overloading. Another type is the portable hoist, which can be mounted wherever convenient; i.e., to a post or timber. It is used for pulling cranks, skidding timbers, pulling a scraper on backfill work, and dozens of other applications.

Tools for Railroad Track Work.—Special pneumatic tools have been developed for a number of applications in railroad track construction and maintenance. There are pneumatic tie tampers for tamping ballast under ties, pneumatic spike pullers, spike drivers, rail drills, pneumatic wrenches, rail bonding drills and others. Tamping ballast with pneumatic tampers is much easier than swinging a pick or tamping with a hand bar. The air tampers strike a uniform blow all day long and produce a uniform track. In removing old rail, the old spikes must be pulled. A compressed-air-operated spike puller draws 10 to 15 spikes per minute. One such machine does as much work as eight to ten men using hand claw bars. The pneumatic wrench removes the nuts or runs up nuts on the joint bolts much faster than is possible with a hand wrench. The air-operated spike driver puts down the spikes in a fraction of the time required by a hand hammer. A pneumatic rail drill bores a $\frac{3}{4}$ in hole through the web of a rail in from 25 to 30 sec. Small holes for signal wires are drilled with pneumatic rail bonding drills at the rate of 60 per hour. (R. A. Lu.)

PNEUMATOLYSIS, in petrology, discharge of vapours from igneous magmas and effects produced by them on rock masses (so called from Gr *πνεῦμα*, vapour, and *λύειν*, to set free). In volcanic eruptions the gases given off by molten lavas are powerful agencies. The sluggy clots of lava thrown out from the crater are so full of gas that when they cool they resemble spongy pieces of bread. The lava streams as they flow down the slopes of the volcano are covered with white steam clouds, while over the orifice of the crater hangs a canopy of vapour which is often darkened by fine particles of ash.

Cause of Volcanic Explosions.—Most authors ascribe volcanic explosions to the liberation of steam from the magma which held it in solution, and the enormous expansive powers which free water vapour possesses at very high temperatures. Of these gases the principal are water and carbonic acid; but by analysis of the discharges from the smaller fumaroles, for the active crater is generally too hot to be approached during an eruption, it has been ascertained that hydrogen, nitrogen, hydrochloric acid, boron, fluoric, sulphuretted hydrogen and sulphurous acid are all emitted by volcanoes. A recent lava flow has been likened to a great fumarole pouring out volatile substances at every crack in its sluggy crust. Many minerals are deposited in these fissures, and among the substances produced in this way are ammonium chloride, ferric chloride and oxide, copper oxide (tenorite and cuprite) and sulphur; by reacting on the minerals of the rock many zeolites and other secondary products are formed. These processes have been described as "juvenile" or "post-eruptive," and it is believed that the amygdaloids which occupy the cavities of many porous lavas are not due really to weathering by surface waters percolating in from above, but to the action of the steam and other gases set free as the lava crystallizes. The zeolites are the principal group of minerals which originate in this way together with chlorite, chalcedony and calcite. The larger

cavities (or geores) are often lined with beautiful crystal groups of natrolite, scolecite, thomsonite, stilbite and other minerals of this order.

Solfataric Activity.—The active gases were evidently in solution in the magma as it rose to the surface. Geologists now believe they are of subterranean origin like the lava itself, and an essential or original component of the magma. Long after a lava has cooled down and become rigid the vapours continue to ooze out through its fissures, and around many volcanoes which are believed to be extinct there are orifices discharging gas in great quantities. This state of activity is said to be solfataric, and a good example of it is the volcano called the Solfatara near Naples. The numerous "solfatras" of the West Indies are further instances. The prevalent gas is steam with sulphuretted hydrogen and carbonic acid. White crusts of alum, various sulphates, and sulphides such as pyrites, also carbonates of soda and other bases, are formed by the action of the acid vapours on the volcanic rocks. The final manifestation of volcanic activity in a solfataric region may be the discharge of heated waters, which have ascended from the deep-seated magma far below the surface, and make their appearance as groups of hot springs, these springs persist long after the volcanoes which give rise to them have become extinct.

Role of Hot Waters.—It is now believed by a large number of geologists and mining engineers that these ascending hot waters are of paramount importance in the genesis of some of the most important types of ore deposits. Analyses have proved that the igneous rocks often contain distinct though very small quantities of the heavy metals, it is also established beyond doubt that veins of gold, silver, lead, tin and mercury most commonly occur in the vicinity of intrusive igneous masses. At Steamboat, Nev., hot springs, probably of magmatic origin, are forming deposits of cinnabar, at Cripple Creek, Colo., and in many other places gold-bearing veins occur in and around intrusive plugs of igneous rock. Tin ores in all parts of the world are found in association with tourmaline granites, and in all cases the veins bear evidence of having been filled from below by hot waters set free during the cooling of the igneous intrusions. Volcanic rocks are consequently the parent sources of many valuable mineral deposits, and the agency by which they were brought into their present situations is the volatile products discharged as the magma crystallized. The process was no doubt a long one and it is most probable that both steam and water took part in it. In what condition the metallic ores are dissolved and by what reactions they are precipitated depends on many factors only partly understood. The tin ores are so often associated with minerals containing boron and fluorine that it is quite probable that they were combined with these elements in some way, but they were deposited in nearly all cases as oxides. Other gaseous substances, such as sulphuretted hydrogen, carbonic acid and hydrochloric acid, probably have an important part in dissolving certain metals, and the alkaline carbonates, sulphides and chlorides have been shown by experiment to act also as solvents. In these ore deposits not only the heavy metals are found, but often a much larger quantity of minerals such as calcite, barytes, fluorapatite, quartz and tourmaline which serve as a matrix or gangue, and have been deposited by the same agencies, and often at the same time as the valuable minerals.

Alteration of Minerals.—In their passage upward and outward through the rocks of the earth's crust, these gases and liquids not only deposit minerals in the fissures along which they ascend, but attack the surrounding rocks and alter them, the granite or other plutonic mass from which the vapours are derived is specially liable to transformation, probably because it is at a high temperature, not having yet completely cooled down. Around the tin-bearing veins in granite there is extensive replacement of feldspar and biotite by quartz, tourmaline and white micas (the last-named often rich in lithia). In this way certain types of altered granite are produced, such as greisen (*g v.*) and schorl rock (*see SCHORL*).

In the slates adjacent to the tin veins tourmalization also goes on, converting them into schorl-schists. The alteration of feldspar into kaolin or china clay is also a pneumatolytic process, and is often found along with tin veins or other types of mineral deposit, probably both fluorine and carbonic acid operated in this instance

along with water. Equally common and important is the silicification of rocks near mineral veins which carry gold, copper, lead and other metals. Granites and felsites may be converted into hard cherty masses of silica; limestones undergo this transformation very readily, at the same time they are regarded as rocks very favourable to the deposition of ores—probably the great frequency with which they undergo silicification and other types of metasomatic replacement is one of the main causes of the abundance of valuable deposits in them. The process known as 'propylitization', which has extensively affected the andesites of the Hungarian goldfields, is believed to be also a consequence of the action of pneumatolytic gases. The andesites change to dull, soft, greenish masses, and their original minerals are to a large extent replaced by quartz, epidote, chlorite, scapolite and kaolin. Around granites intrusive into serpentine and other rocks containing much magnesia, there is often extensive steatization, or the deposit of talc and steatite in place of the original minerals of the rock. Some of the apatite veins of Canada and Norway accompany basic rocks of the gabbro group, it has been argued that the apatite (which contains phosphorus and chlorine) was laid down by vapours or solutions containing those gases, which may play a similar part in the basic rocks to that taken by fluorine and boron in the pneumatolytic veins around granites. In the country rock around the veins scapolite (*q v.*), a lime alumina silicate, containing chlorine, often is substituted for lime-feldspar.

These extensive changes attending the formation of mineral veins are by no means common phenomena, but in many plutonic masses pneumatolytic action has contributed to the formation of pegmatites (*q v.*) (J. S. F.)

PNEUMONIA. An inflammation of the lung, pneumonia was recognized as a disease by the ancients, but no progress was made in knowledge of it until the time of Leopold Auenbrugger (1761) and René Laennec (1819), when order was brought into its classification. From then until the bacteriologic era opened, classification depended on the anatomic or clinical features, and adjectives such as lobar, lobular, broncho-, interstitial, pleural, double, central, croupous and catarrhal were used. Other pneumonias were called aspiration, contusion, hypostatic or terminal pneumonias, depending upon the cause. Although after 1880 various bacteria and viruses were known to cause pneumonia, the modern etiologic classification did not become popular until about 1920. Precise knowledge of the bacterial or other cause permits the use of specific therapeutic or preventive measures and other rational management in the control of the disease. More than 50 different infectious, physical or chemical causes of pneumonia were known by mid-20th century, but of these, relatively few were of common occurrence. Pneumonias may be grouped as follows: (1) Primary, *se.*, those caused by pathogenic cocci, bacilli, viruses and fungi which attack the lung primarily, (2) pneumonias which occur in more or less specific forms as part of systemic infections such as typhalaria, psittacosis, tuberculosis, rheumatic fever, rickettsial and protozoal diseases, lupus erythematosus and others, (3) pneumonias caused by mixed infection induced by physical or mechanical injury of the lung such as shock, debility, passive congestion, aspiration of foreign bodies or fluid, obstruction to airway, atelectasis, trauma and others, and (4) pneumonias caused by the aspiration of oil, by chemicals, by roentgen rays, deficiency of vitamin A, by allergic reactions and other causes.

PRIMARY PNEUMONIAS

Pneumococcal Pneumonia.—The modern era of this disease began with the discovery of the pneumococcus in 1880 by G. M. Sternberg and its association with pneumonia by A. Fraenkel and A. Weichselbaum in 1884. F. Neufeld first pointed out serologic differences among strains of pneumococci in 1910, and shortly afterward F. S. Lister and A. R. Dochez independently classified them into types. Much fundamental work on the bacteriology, etiology, pathogenesis, clinical aspects and treatment of pneumococcal pneumonia was done after 1911 at the Hospital of the Rockefeller Institute under the leadership of Rufus Cole and Oswald Avery. Extensive bacteriologic, clinical and epidemiologic

contributions on the subject were also made notably by Russell Cecil and Maxwell Finland in the United States and by Max Gundel in Germany. Specific immune serum for treatment was largely developed in the 1920s when it reached its greatest effectiveness and popularity as the refined, concentrated form, only to be displaced by the sulfonamide compounds after 1935. These in turn were superseded by penicillin in 1942 and by other antibiotics later.

Etiology.—There are about 75 types and subtypes of pneumococci of which only a few are of clinical importance. Types 1, 2, 3, 4, 5, 7, 8 and 14 account for about 80% of all pneumococcal lobar pneumonias. Type 1 pneumococcus causes about 30% of cases; type 2, 20%; type 3, 10%, the remainder are caused by pneumococci of other types which, in contrast with those mentioned, often are present in the pharyngeal secretions of healthy persons.

Pneumococci are rarely primary invaders of the lung. In almost all instances there is evidence of some preceding condition which injures the lung and favours invasion, especially minor infections of the respiratory tract commonly called colds; chilling of the body; and debilitation. The pneumococci which become invasive are acquired by inhalation from outside sources or are already present in the pharynx; the first circumstance indicates that pneumonia may be a contagious disease contracted from other patients or carriers of pneumococci, and the second that it may arise as an autogenous infection. Under certain conditions when the general resistance is lowered by serious conditions, and in old age, the pneumonia is apt to be atypical (Cole) or lobular (bronchopneumonia); that is, it does not behave like the lobar form. The onset is gradual, consolidation may not occur, and the course is irregular. The pneumococci causing this form are usually of the higher numbered types, indicating that they are part of the normal flora of the respiratory tract which have become invasive.

Pathology.—Pneumococci reach the lung by way of the air passages, settle in an area where they find circumstances suitable for growth, and give rise to an area of inflammation conditioned by complex factors, among which partial immunity, allergy and nervous influences seem to play an important role. The inflammation spreads rapidly, and soon involves part or most of a lobe, first as congestion then with an outpouring of fibrin and polymorphonuclear leukocytes into the alveolar spaces. The exudate becomes rather solid and grayish over a period of several days, and finally, when recovery occurs, it softens and is resorbed. During this time pneumococci often enter the blood stream and may localize on the valves of the heart, the meninges or elsewhere. The pleura may be invaded resulting in empyema.

Epidemiology.—Pneumococcal pneumonia is contagious at times, but susceptibility to infection is largely controlled by the resistance of the host. The prevalence of pneumonia usually parallels the incidence of minor respiratory tract infections, and both are most common in cold months, but may occur at any season. Many household epidemics are on record. Pneumonia varies in incidence from year to year and to some extent in its clinical manifestations, depending on the type of pneumococci predominant at the time. It is most prevalent in the temperate climates but may occur anywhere. All races are susceptible. Men are affected more often than women because of greater hazards to exposure. It is commonest in early adult life.

Pneumococcal pneumonia declined steadily in incidence after the introduction of sulfonamide therapy and penicillin. In the course of untreated patients may last a week or more, during which severe illness occurs. Characteristic signs in the chest in the early stage are those of congestion which soon become those

of consolidation of the lobe or lobes with dullness and other physical signs (bronchial breathing, egophony, pectoriloquy and occasionally friction sounds). Roentgenography is of great aid in observing the location and course of the pulmonary lesion. In patients who develop pleural effusion or empyema, signs of fluid appear. The leukocyte count and sedimentation rate of red cells are usually increased, the blood culture often becomes positive, and the specific polysaccharide of the causative pneumococci may appear in the urine.

In certain patients the onset is gradual and the course is not so characteristic, giving a clinical response named "atypical" pneumonia by R. L. Cole.

In those who recover, improvement often begins abruptly as a crisis with rapid fall of temperature and general improvement unless other involvement occurs. Death is caused by toxæmia, overwhelming infection, circulatory collapse or extrapulmonary localization, the chief of which are empyema, meningitis, endocarditis and arthritis. In patients treated with penicillin or sulfadiazine the course usually is terminated promptly within 24 to 48 hr.

The mortality rate of untreated patients is 30%; of those treated with penicillin, aureomycin or sulfadiazine about 5%. Five per cent is probably a minimum rate, since there are certain instances in which therapy is unsuccessful or for various reasons may be delayed or not available. The disease is more fatal to infants, debilitated or senile patients or to those with other chronic diseases such as diabetes, hypertension or nephritis, or when treatment is postponed. Overwhelming infection may occur which does not respond to any treatment.

One attack of pneumonia does not necessarily predispose a person to another. There are certain persons who, for unknown reasons, have repeated attacks of pneumonia caused by the same type or by different types of pneumococci, or by other bacteria. There is some evidence of a hereditary tendency to the disease in certain family groups.

Treatment.—Diagnosis should be established by clinical, roentgenologic and bacteriologic methods. Material for tests must be obtained before treatment is begun. Penicillin should be given promptly by injection or by mouth daily until the temperature becomes normal and for several days afterward. Aureomycin, chlaramphenicol, terramycin or sulfadiazine may be used if penicillin is unavailable or ineffective. Possible toxic effects of sulfadiazine and antibiotics should be anticipated. Appropriate symptomatic treatment must be given.

Prevention.—The fundamental measures of prophylaxis are the prevention of minor respiratory tract infections and other conditions which predispose to pneumonia and the control of carriers of pneumococci. The maintenance of general health by adequate food, exercise and rest are important. Specific vaccines prepared with killed pneumococci have been used experimentally but are of little practical value. Vaccine consisting of specific pneumococcal polysaccharides is said to be of superior value, but is of practical advantage only among well-controlled groups.

Haemolytic Streptococcal Pneumonia.—This form of pneumonia is less common than the pneumococcal forms and occurs often as a complication of influenza as it did in the pandemic of 1918-19. It is caused by any of the 27 or more types of group A beta haemolytic streptococci. It may occur in sporadic or in epidemic form, the latter depending on the epidemiology of the predisposing viral infection.

The bronchi and trachea are involved more often and more severely than in pneumococcal pneumonia. There is lymphangitis and more involvement of interstitial tissues. The exudate is haemorrhagic and streptococci are numerous. The pleura is usually inflamed.

Symptoms.—The symptoms are not characteristic. The disease often begins as an aggravation of the mild primary disease. There are fever, cough, pain in the chest, chills or chilly sensations and prostration, in widely varying degrees of severity. The sputum is often thin, mucopurulent and bloody. Bacteraemia is uncommon. The leukocytes may be normal or increased in number. Massive pleural effusion with serosanguineous fluid or

empyema are common. The patient may be mildly sick or extremely so with ashy pallor, cyanosis and evidence of circulatory collapse. The pulmonary signs are chiefly those of atypical pneumonia with patchy areas of congestion and areas of undeveloped consolidation. Flatness is present over an effusion.

The mortality rate in untreated patients at mid-20th century varied from 10% to 60%, not enough patients had been treated to judge the beneficial effects of penicillin or sulfadiazine.

The diagnosis is made chiefly by the epidemiologic characteristics of the disease and by the predominance of a specific type of haemolytic streptococcus of group A in the sputum, blood or exudate. Retrospective diagnosis may be made by the demonstration of specific precipitins, antistreptolysin and antifibrinolysin in the blood. Roentgenography is useful in determining the nature and extent of the pulmonary lesions.

Treatment.—Penicillin is indicated and must be given in large dosage. Sulfadiazine is said to be of some value. The symptomatic treatment is the same as for other pneumonias. Pleural effusions should be repeatedly aspirated and if empyema is present, penicillin must be injected into the cavity.

Staphylococcal Pneumonia.—The staphylococcus, like the haemolytic streptococcus, may invade the lung particularly during minor viral infections of the respiratory tract. A large outbreak occurred in the influenza pandemic of 1918-19. Staphylococcal pneumonia may occur in epidemic form during epidemics of viral diseases of the respiratory tract or as sporadic cases.

The causative staphylococci are usually those which are normally present in the patient, but they may be acquired from outside sources. They invade pulmonary tissue injured by other infectious agents, chiefly viruses, and give rise to patchy areas of inflammation. In the course of several days, multiple small abscesses form and tend to coalesce.

The symptoms usually are imposed upon a previous cold and usually begin gradually. They vary greatly in intensity from mild to fulminating and are characterized by a high irregular fever, chills or chilliness, sweating, cough and uncharacteristic staphylococcal-laden sputum. The leukocyte count is variable and bacteraemia seldom occurs. In severe cases there are cyanosis and prostration. As abscesses form and discharge, the sputum becomes purulent, increases in amount and the signs change from those of patchy pneumonia to those of cavitation. The mortality rate is variable; in some series of cases, most patients recovered and in others 70% died.

Diagnosis is based on the epidemiologic aspects of the disease, the presence of great numbers of staphylococci in the sputum, their presence in the blood stream or in exudates, and the signs and roentgenographic evidence of the development of multiple cavities.

Treatment.—Penicillin is the agent of choice, but it must be given in large amounts parenterally.

Friedlander's Bacillus Pneumonia occurs chiefly in debilitated or senile persons. The onset is often like that of pneumococcal pneumonia, and the disease is often characterized by a severe course, with chills, but with less pronounced evidence of true consolidation of the lung and an irregular fever. The sputum is bloody, mucous or mucopurulent and contains a predominance of capsulated gram-negative coccobacilli. A chronic form with cavitation resembling tuberculosis may develop.

Because the disease occurs chiefly in debilitated or senile persons its mortality rate is high, and is said to be 50% to 70%.

The treatment is not as effective as for other forms of pneumonia. Good results were reported from the use of sulfadiazine. Only a few patients up to 1951 had been treated with streptomycin, and the results were said to be good.

Rarer forms of pneumonia are caused by *H. influenzae*, *B. anthracis*, *P. pestis*, *Coccidioides immitis*, *Coccidioides burnetii* (Q fever) and others. (See TUBERCULOSIS for tuberculous pneumonia.)

The Viral Pneumonias.—While much attention was given to the bacterial forms of pneumonia because of their seriousness, little was paid to pneumonias of viral origin because they seldom caused death and the technique of handling viruses remained

difficult. Viral diseases such as measles were known to be characterized by pneumonia as early as 1861, but the nature of the pulmonary lesion was obscured by the activity of secondarily invading bacteria. However, the experimental production of bacteria-free pneumonia with the viruses of vaccinia, influenza and others, and the absence of bacteria in the lungs of patients who died during the influenza pandemic of 1918 left no doubt that viruses cause pneumonia. Pneumonia is a common occurrence in smallpox and influenza and has been described in chickenpox, vaccinia and lymphocytic choriomeningitis. Between 1920 and 1938 European and U.S. roentgenologists demonstrated unsuspected pneumonias by roentgenography in ambulatory and bed-fast patients with undifferentiated mild respiratory tract diseases. These pneumonias were different from the bacterial forms.

Wide interest in the subject followed the establishment of viral pneumonias as a separate entity by H. A. Remann in 1938. Apparently there are a number of viral pneumonias caused by different agents, some occurring in epidemic form and others as sporadic cases. The epidemic forms of pneumonia apparently represent the severest cases of otherwise mild infections of the respiratory tract called colds, grip or pharyngitis. The sporadic cases resemble the pneumonias of psittacosis or ornithosis, but since the agents causing the latter can be seen microscopically and are influenced by antibiotics, their classification as viruses is questioned.

Confusion in nomenclature of this group of diseases is not surprising since up to 1951 the cause or causes of them had not been discovered. The term "atypical pneumonia" became widely used, but is undesirable since in Cole's view, any pneumonia not clinically the same as typical pneumococcal pneumonia is atypical, and furthermore pneumonia is absent in the majority of mild diseases of which most viral pneumonias represent the severest stage. The broad term "viral pneumonia" is preferable since all evidence, except the final proof of demonstrating a virus, indicates that viruses are the cause. The name "viroid" was proposed to include both pneumonic and nonpneumonic forms of the respiratory tract disease in question.

In the search for the cause of viral pneumonias, about 25 related or unrelated viruses had been encountered up to 1951, most of which proved to be natural residents of animals used in the experiments, so that the cause or causes still were unknown. However, all other facts pointed to a viral cause, especially the epidemiologic aspects of the disease, the absence of special bacteria in the sputum, the absence of any bacteria in the lungs at necropsy, and experiments in which volunteers inhaled filtered bacteria-free exudates from patients with the disease and developed respiratory tract disease several days later with or without pneumonia, identical with the natural form.

The pneumonic forms begin with symptoms of gradually increasing severity over several days. There is headache, dry paroxysmal cough, slight sore throat, sweating and fever which is irregular, but seldom high, a pulse rate often relatively slow, slight indefinite or absent physical signs of pneumonia which are strikingly less than the roentgenographic evidence of pulmonary invasion, a normal or slightly elevated leukocyte count and rate of sedimentation of erythrocytes, followed by recovery by lysis and few complications. Encephalitis occurs in a small number of patients. Pleural effusion is uncommon. The mortality rate is 0-2%. The few deaths which occur are caused by circulatory collapse, severe infections and by the presence of other disease or complications.

The incidence of viral pneumonias varies from year to year but great increases in number of cases come with epidemic periodicity. Epidemics occur at any season of the year, but most commonly in the winter months. During the years 1941 to 1944 viral pneumonias outnumbered all other forms of pneumonia in military groups and among civilians.

Diagnosis is made on the epidemiologic aspects, the clinical behaviour, the leukocyte count and the absence of the usual bacterial causes of pneumonia in the sputum. Retrospective diagnosis may be aided by the ability of the serum to agglutinate erythrocytes at low temperature (the cold-agglutinin test) after the tenth day

of disease in 50% of cases. Diagnosis of the pneumonia of influenza of Q fever, of psittacosis and of ornithosis, is made by isolation of the respective causative agents or the serologic demonstration of their activity by appropriate tests. The pneumonias of psittacosis, ornithosis, Q fever, coccidioidomycosis, tularemia, tuberculosis and other known forms may closely resemble the viral pneumonias of unknown cause and must be differentiated since specific therapy for some of them is available. Penicillin and aureomycin are effective for psittacosis and ornithosis, and streptomycin for pneumonia caused by the influenza bacillus and for tularemia and tuberculosis.

Pathologically, viral pneumonias are characterized by involvement of the structure of the lung and the larger air tubes, and an exudate composed chiefly of mononuclear cells. The mucous membrane of all or of parts of the upper respiratory passage may be inflamed and invaded with mononuclear cells. No bacteria are present in the tissue unless secondary invasion occurs.

Treatment—Penicillin, sulfonamide compounds and streptomycin have no effect on viral diseases. They are used if complications occur caused by pathogenic bacteria susceptible to their effects. Aureomycin, chloramphenicol and tetracycline apparently shorten the course in many instances, in others, no effect is evident. Convalescent serum and roentgenotherapy are of no value. Oxygen is helpful for cyanosis and dyspnea.

THE OTHER GROUPS OF PNEUMONIAS

Pneumonias of Systemic Diseases.—Pneumonia may occur as an integral part of many systemic diseases. It may dominate the clinical picture, or be a minor factor or not occur at all in tuberculosis, tularemia, plague, undulant fever, glanders, syphilis, rheumatic fever, ascariasis, peritonsillar nodosa, sarcoidosis and many others. The pneumonia is usually not characteristic clinically and is often obscured by symptoms of disease elsewhere. Pathologically it may assume features characteristic of the respective disease. The treatment is that of the disease itself.

Pneumonia of Mixed Infections.—The pneumonias brought about by injury to the lung or interference of their self-cleansing process by obstruction of the airways, foreign bodies, tumours, failing circulation, submersion in or aspiration of fluids, trauma after surgical operation, shock and many other causes, are usually caused by a mixture of various kinds of bacteria which reside habitually in the air passages and are enabled to become invasive by the presence of injured tissue. Pneumococci, influenza bacilli, haemolytic streptococci and staphylococci are most frequently implicated. The treatment is primarily directed at correcting or removing the primary cause, the use of antibiotic agents according to the sensitivity of the invading bacteria to the respective agents, and appropriate supportive measures.

Pneumonia Caused by Noninfective Agents.—The aspiration of oil over long periods or in large amounts often causes a form of chronic reaction commonly called lipid pneumonia. Long exposure to roentgen rays may also give rise to a pulmonary reaction called irradiation pneumonitis which leads to fibrosis. The inhalation of certain irritating chemicals and certain gases used in warfare or for industrial uses, or fumes from certain molten metals may cause forms of pneumonia. Allergic pneumonitis or Loeffler's syndrome apparently represents the hyperergic inflammatory reaction of sensitized lung tissue to repeated exposure to the specific antigen. The treatment of each condition mentioned under this heading is the removal of the offending agent.

BIBLIOGRAPHY—R. I. Cole, *Acute Pulmonary Infections*, DeLamar Lectures, 1927-28 (1928); R. Heffron, *Pneumonias with Special Reference to Pneumococcus Lobar Pneumonia*, The Commonwealth Fund (1939); H. A. Reimann, *The Pneumonias* (1938). (H. A. Re.)

PNEUMONOCONIOSIS is the term applied to an industrial or occupational disease of the lungs which has for its distinguishing feature the formation of fibrous tissue in the lungs—pulmonary fibrosis.

The disease has been recognized since earliest times. Pliny and Hippocrates described it, and so did Agricola in 1556. It was gold mining in South Africa that focused attention on dust diseases of the lungs about the turn of the 20th century. In 1916 the Miners'

Phthisis Prevention committee of the Union of South Africa issued a comprehensive report and the South African authorities thereafter were in the forefront of investigation and research. Extensive investigations of working conditions and laboratory research were carried on in the Union of South Africa, England, Australia, Canada, the U.S., Germany, Italy and other countries.

Pneumoconiosis is a generic term and includes such specific diseases as silicosis, asbestosis and pneumoconiosis produced by diatomaceous earth, and also anthracosis, produced either by coal dust alone or in combination with silica. The dusts that produce pneumoconiosis are inorganic. Excluded from consideration are organic dusts, living organisms (bacteria, fungi) and so-called toxic dusts. These, such as lead, mercury or arsenic, are systemic poisons and do not produce the characteristic fibrous changes which are typical of the pneumoconioses.

Silicosis is the most important form of pneumoconiosis because of its severity and its frequent association with tuberculosis; also because the number of persons exposed to the silica hazard is much greater than for the other dust diseases. Formerly the terms miners' phthisis, grinders' rot, potters' rot and similar local designations were in use to describe the condition.

Silicosis arises only under certain conditions: (1) The dust must contain pure silica (SiO_2). With the exception of asbestos, a silicate, silica dust is the principal dust that can cause disability and death. (2) The dust particles must be sufficiently small, not more than five microns in greatest diameter, in order to penetrate through the finer air passages and reach the actual breathing spaces where the absorption of oxygen from the air takes place. (3) There must be sufficient concentration of dust in the air. In the United States a concentration of 5,000,000 particles per cubic foot is the generally accepted maximum allowable concentration. This standard is accepted by the United States bureau of mines and the United States public health service. Studies indicate that if this concentration is not exceeded, a disabling pneumoconiosis is not likely to be produced in the average working lifetime. (4) The exposure of the individual must be over a sufficiently long period. Widespread measures for dust control have been adopted in mines and factories, and the development of silicosis is most frequently a matter of years (10 to 20). (5) The element of individual susceptibility seems to play a part, but to what extent it is not possible to define accurately.

The cardinal symptom of silicosis is a gradually increasing shortness of breath (dyspnoea). This may appear after ten or more years of exposure, depending upon the various factors mentioned above. If the exposure is continued, disability may result and the silicotic may become a victim to a complicating tubercle infection. The diagnosis depends upon the roentgenogram of the lungs which is characteristic, plus a history of exposure to siliceous dust.

The prevention of silicosis depends upon engineering control and medical supervision. Engineering control in mine, mill or factory implies the trapping of the dust at its source, as far as practicable, before it can be disseminated into the air; also adequate ventilation which serves to dilute the dust, exhaust equipment applied to different types of machinery, and the use of water to lay the dust and similar measures. Once the dust becomes distributed in the atmosphere of working places, the protection of the individual becomes difficult and unsatisfactory. Respirators are of little avail, except the positive pressure type, and these are not applicable to many occupations. The average workman cannot wear a respirator and do hard work all through a working shift, day after day, especially if the work place is hot and humid.

Asbestosis and the pneumoconioses of coal miners are among other important forms of pneumoconiosis. The method of occurrence is identical—breathing dust-laden air. The pathology differs more or less from silicosis but the procedures for diagnosis and prevention are similar.

See A. J. Lanza (ed.), *Silicosis and Asbestosis* (1938). (A. J. L.)

PNEUMOTHORAX. The chest is divided into two airtight compartments by the mediastinum. A thin membrane called the pleura (see COELOM AND SEROUS MEMBRANES) covers each lung, and is reflected at the root of the lung to form the lining of the

inner surface of the chest wall. Normally the visceral pleura (covering the lung) is in contact with the parietal pleura (covering the inner surface of the thorax), and the potential space between them is spoken of as the pleural space. A pneumothorax exists if the two layers of pleura are separated by air and the lung collapses away from the chest wall. Air may be introduced into the pleural space as the result of trauma, by spontaneous rupture of the visceral pleura or by means of a needle inserted through the chest wall.

Traumatic Pneumothorax.—Since the lung is an elastic organ and tends to be pulled toward the lung root, the pressure in the pleural space is less than atmospheric, averaging minus five centimetres of water. This means that air under atmospheric pressure will be sucked into the pleural space if the visceral pleura is torn (e.g., by a fractured rib) or if an open wound in the chest wall penetrates the parietal pleura. If a "sucking wound" of the chest wall exists, more air may be pulled into the pleural cavity via the wound than is pulled into the lung via the larynx, with the result that the collapsed lung and mediastinum are pushed toward the healthy side on inspiration and away from it on expiration. This paradoxical motion of the lung and mediastinum causes progressive asphyxia unless the wound is closed.

Spontaneous Pneumothorax.—The sudden collapse of the lung without previous trauma is termed spontaneous pneumothorax, and is usually associated with severe chest pain and difficulty in breathing. Most cases occur in apparently healthy persons. Because spontaneous pneumothorax may occur as a complication of pulmonary tuberculosis, it was assumed for years that almost all cases were due to tuberculosis. This is not true. In 1932 H. Kjaergaard suggested that emphysematous blebs in the pleural surface of the lung were the common cause of spontaneous pneumothorax, and this concept was later confirmed. Superficial blebs on the pleural surface are weakened areas of pleura, and may blow out as a result of suddenly raising the intrapleural pressure by lifting, coughing or laughing.

Artificial Pneumothorax.—In 1882 Carlo Forlanini first reported the successful use of artificial pneumothorax in the treatment of pulmonary tuberculosis, and placed the method on a firm scientific basis. The primary aim of artificial pneumothorax is the closure and healing of ulcerations (cavities) in the lung. This is accomplished by relaxation of the collapsed lung and presumably by the occlusion of small bronchi draining cavities.

Air is introduced into the pleural space by means of a needle attached by a rubber tube to a bottle. Water is siphoned into the bottle slowly, thus displacing air which is forced into the pleural cavity. Small amounts of air are introduced daily until the lung is suitably collapsed, and the pneumothorax is maintained by periodic refills at varying intervals (usually one to three weeks) depending upon the rate of reabsorption of air. Artificial pneumothorax is usually maintained for two to five years unless cavity closure does not occur or complications necessitate earlier re-expansion. Complications of pneumothorax therapy are frequent and include accumulation of fluid in the pleural space, formation of adhesions between the two layers of pleura, infection of the pleural space (empyema) and reduction of the patient's respiratory reserve after the lung has been re-expanded. Because of these limitations other procedures such as thoracoplasty and pulmonary resection are often more suitable for treatment of cavernous tuberculosis. Artificial pneumothorax is sometimes used for diagnostic purposes to distinguish on X-rays between pneumonia in the lung and pleura, and is used by some thoracic surgeons preliminary to pulmonary resection. It has no value in the treatment of other pulmonary diseases.

(R. H. E.)

PNOM PENH, capital of Cambodia (g.v.), Indochina. Pop. (1936) 103,000 (Cambodians, Annamese, Chinese, Malays). The city is on the Mekong river, 173 mi. from its mouth, at the junction with the Tonle Sap.

Steamers connect Pnom Penh with Saigon and with many towns on the Mekong and the Tonle Sap. Excellent highways lead to Saigon, Angkor Wat, Bangkok and northern Indochina. It is the terminus of railway from Singapore and Bangkok. Rice, fish, cotton, rubber and forest products are the chief items of a trade affecting all of Cambodia and Laos, and parts of Thailand in the Mekong valley. The citadel, in the centre of the city, contains the king's palace and residences of senior French officials.

PO (anc. *Padus*, Gr. *Πάδος*), a river of southern Italy, and the dominating factor in its geography. It is the longest river in Italy (310 mi. direct, 420 mi. including its many windings), and the area of its basin, which includes portions of Switzerland, is estimated at 26,798 sq. mi. For its course and principal tributaries, see ITALY. The lower valley of the Po was at an early period occupied by people of the Palaeolithic and Neolithic stages of civilization, who built houses on piles along the swampy borders of the streams. The river regulation works originated in pre-Roman times. The reclaiming and protecting of the riparian lands went on rapidly under the Romans, and in several places the rectangular divisions of the ground are still remarkably distinct (See ESTE). During the barbarian invasions much of the protective system decayed but the later middle ages saw the works resumed, so that the present arrangement existed in the main by the close of the 15th century. The Ligurian name of the Po was Bodincus or Bodencus; i.e., the bottomless. The name Padus was taken from the Celts or the Veneti. Thus Bodincomagus is found as a town name (Industria) on the upper course, and Padua as a name of one of the mouths of the river. The name *Ἡ πόσις* (Eridanus) of Greek poetry was identified with it at a comparatively late period.

See A. Beltrame, *Da Comacchio ad Argenta* (Bergamo, 1905), A. Cappellini, *Il Polesine* (Kovigo, 1925).

POBÉDONOSTSEV, CONSTANTINE PETROVICH (1827-1907), Russian jurist and state official. Born in Moscow in 1827, he studied at the School of Law in St. Petersburg, and entered the public service as an official in one of the Moscow departments of the senate. In the early years of the reign of Alexander II (1855-1881), Pobédonostsev maintained that occidental institutions were radically bad in themselves and totally inapplicable to Russia. Parliamentary methods of administration, modern judicial organization and procedure, trial by jury, freedom of the press, secular education—these were among the principal objects of his aversion. He therefore persecuted the dissenters, Stundists, Doukhobors and others, and insisted on severe measures of repression in education and in the press. He exercised considerable influence by inspiring and encouraging the Russification policy of Alexander III (1881-1894). Pobédonostsev died on March 23, 1907.

POCAHONTAS (1595-1617), daughter of the Indian chief, Powhatan, is the heroine of one of the best-known traditions connected with the beginnings of American history. The story is that Capt. John Smith, as head of a band of soldiers in search of food and exploring the Chickahominy river, was waylaid by Indians and taken prisoner by their chief, Powhatan. Smith had been forced to kneel down while his head was laid on a stone preparatory to having his brains crushed out with heavy clubs, when Pocahontas, a young daughter of the chief, sprang forward, seized his head in her arms, and saved his life. She is supposed to have come again to his aid a year later by revealing a plot made against Smith by her father. All this is said to have happened in connection with the expedition under Capt. Bartholomew Gosnold and others, who landed in Chesapeake bay in 1607, explored the James river, and formed a settlement. Owing to the fact, however, that no mention of this experience is made in the minute personal narrative covering this period, written by Capt. Smith at the time of the supposed occurrence and published immediately thereafter, nor in the recollections of his comrades who usually gave him full credit for any of his exploits, doubts have arisen as to the authenticity of the tale. The first story concerning Pocahontas appears in the *General History*, first published in 1624, after she had been made much of in England as the attractive daughter of an emperor and the first convert of her tribe to Christianity, and it is to be feared that the temptation to bring her on the stage as heroine in a new character in connection with Smith, ever the hero of his own chronicles, was more than he or the publishers of the *General History* could withstand. Many prominent Virginia families trace their ancestry to the son of Pocahontas and her husband, John Rolfe.

POCATELLO, a city of southeastern Idaho, U.S., on the Portneuf river, at an altitude of 4,660 ft. 22 mi. S. W. of

Yellowstone National park; the county seat of Bannock county. It is on federal highways 30N and 92 and the Union Pacific railway system, and has a municipal airport.

The population was 26,131 in 1950, 18,133 in 1940 by federal census. Beyond the Snake river (15 mi distant) to the north and west stretches the Snake river lava plain of 20,000 sq mi. American Falls (1950 pop. 1,874), 23 mi W of Pocatello, is the centre of a great hydroelectric power and irrigation project. Pocatello has extensive railroad shops and a variety of manufacturing (including cheese factories, feed mills, wheat elevators, phosphate fertilizer plants and huge electric furnaces producing elemental phosphorus). A U.S. navy ordnance plant which services the guns of the Pacific fleet is also located there. It is the home of Idaho State college, a state-operated liberal arts college. Seven miles north is the Fort Hall Indian reservation, and within its limits is the site of old Fort Hall, built in 1834 at the intersection of the Missouri-Oregon and the Utah-Canada trails. At Massacre Rocks, 38 mi S.W. of Pocatello, an emigrant train was annihilated by Indians in Aug. 1862. The city is built on 2,000 ac. sold by Indians to the U.S. It began as a tent colony in 1881, when the railroad was completed to this point, and was incorporated in 1892. Its growth was attributable at first to the railroad shops, and later to irrigation projects.

POCHARD, a diving duck, *Nyroca ferina*, the female of which is sometimes called the dumbird. In the male in full plumage the head is coppery-red, the breast black, and the back and flanks a dull white, closely barred with fine undulating black lines. The tail coverts and quill feathers are black and the lower surface dull white. The female is duller. The pochard breeds throughout the northern hemisphere, migrating to the coast in winter and returning southward. The American subspecies is larger. A second American species is the much bigger canvasback duck (*q.v.*). Both species are excellent table birds when they frequent fresh water, the canvasback being pre-eminent. Allied to the pochards are the scaup duck (*N. marila*), the tufted duck and the eiders.

POCKET GOPHER, the name of a group of (chiefly North) American ratlike rodents, characterized by large cheek pouches, the openings of which are external to the mouth, while their inner surface is lined with fur. The second and third front claws are greatly enlarged, and the fingers are furnished along their sides with bristles. The eyes are small, and the external ears rudimentary. Pocket gophers, which typify a family, the Geomyiidae, spend practically all their time underground, their powerful claws being adapted for digging, while the bristles on the toes prevent the earth from passing between them. The upper incisor teeth are employed to loosen the ground, like a fork, and the little rodents are able to move both backward and forward in their runs. The cheek pouches are employed in carrying food, which consists of roots. The common pocket gopher, *Geomys bursarius*, of the Mississippi valley measures about 8 in. in length, plus a tail of between 3 and 4 in.; its colour being rufous brown and grayish beneath. Another well-known representative is the northwestern plains pocket gopher *Thomomys talpoides*, which is considerably smaller than the former. (See **RODENTIA**.)

POCKET MOUSE, the name of a number of small mouse-like, chiefly North American rodents belonging to the family Heteromyidae and including several genera, all with fur-lined external cheek pouches, like the pocket gophers. The typical pocket mice (*Perognathus*) are small, with rather long tails and hind feet. They live in deserts and on the Great Plains, feeding on seeds. Kangaroo mice (*Microdipodops*) are closely related to them but have a very broad head. *Heteromys* and *Liomys*, the spiny pocket rats, have bristles mixed in their pelage. They are dark gray or blackish in colour. Most species of these two genera are Central American, extending to northern South America. (J. E. H.)

POCOCKE, EDWARD (1604-1691), English orientalist and biblical scholar, the son of a Berkshire clergyman, was educated at Corpus Christi college, Oxford. He discovered in a Bodleian ms. the missing Syriac versions of the four New Testament epistles (2 Peter, 2 and 3 John, Jude) which were not in the old

Syriac canon, and were not contained in European editions of the Peshito. His edition of these was published at Leyden in 1630. In 1649 he published the *Specimen historiae arabum*, a short account of the origin and manners of the Arabs, taken from Barhebraeus (Abulfaragius), with notes from a vast number of his sources. This was followed in 1655 by the *Porta Moysi*, extracts from the Arabic commentary of Maimonides on the Mishna, with translation and learned notes, and in 1656 by the annals of *Eutychius* in Arabic and Latin. His *magnum opus*—a complete edition of the Arabic history of Barhebraeus (*Greg. Abulfaragii historia compendiosa dynastiarum*), was dedicated to the king in 1663. After this his most important works were a *Lexicon heptaglotton* (1669) and English commentaries on Micah (1677), Malachi (1677), Hosea (1685) and Joel (1691).

PODEBRAD, GEORGE OF (1420-1471), king of Bohemia, was the son of Victoria of Kunstat and Poděbrad, a Bohemian nobleman, who was one of the leaders of the "Orphans" or modern Taborites during the Hussite wars. George became prominent early as leader of the National, or Calixtine party in Bohemia, becoming its chief at the death of Pláček of Písek in 1448, during the minority of Ladislaus Posthumus, having raised a force of 9,000 men in northeast Bohemia, where the National cause was strongest and where his own ancestral castle was situated, he marched on Prague and took it, afterward defeating the Romanist or Austrian party led by Ulrich von Rosenberg. In 1451 the emperor Frederick III, Ladislaus' guardian, entrusted Poděbrad with the administration of Bohemia. In the same year a diet assembled at Prague also conferred on Poděbrad the regency. The struggle of the Bohemians against Rome continued uninterrupted, and Poděbrad's position became very difficult when Ladislaus, who was crowned in 1453, expressed his sympathies for the Roman Church, though recognizing the compacts and ancient privileges of Bohemia. In 1457 King Ladislaus died suddenly. Public opinion from an early period accused Poděbrad of having poisoned him; but the suggestion is undoubtedly a calumny. On Feb. 27, 1458, the estates of Bohemia unanimously chose Poděbrad as king, even the adherents of the Austrian party voting for him. A year later, Pius II became pope, and his hostility proved a serious obstacle to Poděbrad's rule.

Though refusing to let the compacts be abolished, as Pius demanded, Poděbrad placated him by punishing the most advanced enemies of the papacy, including the newly-founded community of the Bohemian brethren; but his endeavours to establish peace with Rome proved ineffectual, although the death of Pius II prevented him from carrying out his planned crusade against Bohemia. Despite the prosperity enjoyed by Bohemia under Poděbrad's rule, the malcontent nobles of the Romanist party, meeting on Nov. 28, 1465, at Zelena Hora, formed a confederacy against him which was supported by the Roman see. On Dec. 23, 1466, Paul II, the successor of Pius II, excommunicated Poděbrad and pronounced his deposition as king of Bohemia, forbidding all Romanists to continue in his allegiance. The emperor Frederick III, and King Matthias of Hungary, Poděbrad's former ally, joined the insurgents. Matthias conquered a large part of Moravia and was crowned king of Bohemia at Brunn on May 3, 1469. On March 22, 1471, Poděbrad's death ended the war. He was the only native king of Bohemia, and the only one not a Catholic.

PODGORICA, the commercial capital of Montenegro, Yugoslavia. Pop. (1931) 10,651. The town lies in a fertile plain on the Moracha, there spanned by a fine old Turkish bridge, while a tributary separates the Turkish town lying within the ruined ramparts, and inhabited by Albanians, from the Montenegrin quarter built in 1878.

PODIATRIST: see **CHIROPODIST**.

PODIUM, in architecture, a continuous pedestal, a low wall supporting columns, or the lowest portion of the wall of a building when given a separate archi-

PODIUM, SHOWING MOULDED BASE, PLANE SURFACE OR DADO, AND CORNICE

tectural treatment. Sometimes the basement (*gv*) story of a classical building may be treated as a podium. The podium is usually designed with a moulded base and plinth (*gv*) at the bottom, a central plane surface known as a die or dado, and a projecting cornice or cap. The majority of Etruscan and Roman temples were raised on podiums and the entrance steps ascended between wing walls which were the continuations of the podium at the sides.

PODMOKLY (Ger Bodenbach), a town on the Elbe in northwest Bohemia, Czechoslovakia. Situated on the main Prague-Dresden-Berlin railway, it is an important junction with a transit trade, in part supplied by its industries, which include textiles, porcelain, chemicals and foodstuffs. Pop (1947) 17,558.

PODOCARPACEAE: see GYMNOGERMES.

PODOLSK, a town of the Russian SFSR, 55° 27' N., 37° 28' E, 26 mi S of Moscow, on the railway and on the Pakhra river, crossed by a suspension and a railway bridge. Pop (1939) 72,422. It manufactures cement, lime, silicates and silk goods and has a railway repair shop. Until 1781 it was a dependency of the Danilov monastery of Moscow. Near it is an unkempt park on the banks of the Pakhra, on the former estate of Count Tolstoy.

PODOPHYLLIN, a drug obtained from the rhizome of the American mandrake or May apple. As met with in commerce, the rhizome occurs in cylindrical pieces 2 or 3 in long and about ½ in in diameter, of a chocolate or purplish-brown colour, smooth, and slightly enlarged where the juncture of the leafy stem is indicated by a circular scar on the upper and a few broken rootlets on the under side. The odour is heavy and disagreeable, and the taste acid and bitter.

Podophyllin is a resinous powder obtained by precipitating an alcoholic tincture of the rhizome by means of water acidulated with hydrochloric acid. The powder is soluble in alcohol and strong solutions of alkalis. There are at least two resins in the powder (which is known officially as *Podophyllin resin*), one being soluble and the other insoluble in ether. Each contains an active substance, which can be obtained in crystalline form, and is known as podophyllotoxin. It is soluble in alcohol, ether, chloroform and boiling water. The properties of podophyllin resin vary with the reaction of the tissue with which it is in contact; where this is acid the drug is inert, the picropodophyllin being precipitated.

Podophyllin was known to the American Indians, who realized its cathartic and escharotic properties. It is no longer included in the *Pharmacopoeia of the United States of America*. The *British Pharmacopoeia* recognizes preparations from an Indian species, *P. emodi*. Podophyllin is used chiefly for its cathartic properties in patent medicines, often combined with aloes or calomel. It should be used cautiously since its intense action may lead to inflammation of the bowel and death. It finds some use applied locally to certain types of warts. (See MAY APPLE.)

PODOSTEMONACEAE, a remarkable family of dicotyledonous plants, living only on rocks in rushing streams. The seeds are shed on the rocks during the dry season, germinating when the rocks become submerged in the rainy season. The vegetative parts consist mainly of a flattened green thallus, usually derived from adventitious roots. There are 40 genera and about 175 species, nearly all tropical, a single representative, *Podostemon Ceratophyllum* (river weed), occurring in North America, found in shallow streams from Maine to Minnesota and southward to Georgia and Alabama. For a treatment of the genera, see A. Engler, "Podostemonaceae." Engler and Prantl, *Naturlichen Pflanzenfamilien*, ed. 2, 18a:3-68, fig. 1-61 (1930).

POE, EDGAR ALLAN (1809-1849), American poet and critic, cultivated the literature of mystery, and is himself, to a great extent, a mystery. His work owes much to the drift of romanticism (of which he is a late heir) toward the occult and the satanic. It owes much also to his own feverish dreams, to which he applied a strange power of logic and a rare faculty of shaping plausible fabrics out of impalpable materials. With an air of objectivity and spontaneity, his productions are closely dependent on his own idiosyncrasy and an elaborate technique

years old when his mother, a young English actress, the widow of a U.S. player, died at Richmond, Va., in 1811. The well-to-do childless Mrs. Allan, who adopted him, gave him motherly care and affection—reluctantly seconded by her husband. Edgar received a good education, first in England, then in a private school at Richmond, then went, in 1826, to the University of Virginia, Charlottesville. Differences arose between him and his foster father. Prevented from returning to college after the end of

BY COURTESY OF THE AGENCY OF ARTS AND SCIENCES
POE'S COTTAGE AT FORDHAM, NEW YORK CITY (RESTORED)

the first year, the youth ran away to Boston, where he enlisted in the army. For three years he was a soldier (1827-31)—the last three months in the capacity of a cadet at West Point. His inclination led him toward writing. In spite of untoward circumstances and uncongenial surroundings, he wrote poetry, which he managed to have published in Boston (*Tamerlane*, 1827), in Baltimore, Md., (*Al Aaraaf*, 1829) and in New York city (*Poems*, 1831). Poe settled as a man of letters at Baltimore in 1832, and struggled with poverty, at times with actual want, upheld by his pride and his set resolution to achieve work that would count in the U.S. and in the world. He had neither family nor friends. Disappointments in love and social slights threw a sombre cloud over his disposition. He was afflicted with a strange susceptibility to the effects of liquor, combined with an attraction toward it which he did not always resist successfully.

It was this defect (or hereditary flaw) that, in a large measure, made it impossible for him to remain literary editor, in Richmond, Va., Philadelphia, Pa., or New York city, of magazines which he had raised to prosperity; that later discouraged J. R. Lowell from taking him as contributor to the *Pioneer*; that disqualified him for a clerkship in a government office at Washington, D.C. He made worthy efforts to abstain from stimulants after he had married Virginia Clemm (1836), but relapsed when his child wife fell dangerously ill, in 1841, with scant hope of recovery. After the death of Virginia, in 1847, his morbid condition grew worse and seems to have assumed the form of a lesion of the brain with temporary crises of delirious fever. "I became insane," he wrote, "with intervals of horrible sanity." His last years were marked by fits of platonic erotomania, the objects of which were successively or at the same time women of letters, such as Mrs. Frances Sargent Osgood, Mrs. Shew (Maria Louise), Mrs. Whitman (Helen), Mrs. Lewis (Stella), and new or old friends, like Annie and Mrs. Elmira Shelton.

Poe died after letting himself be entrapped into drinking too much liquor at Baltimore, in 1849.

For 40 years he had fought, against terrible odds, to keep his genius clear and accomplish the work of a creative artist. While continuing to write verse, he began composing prose tales in 1832, and started a career as literary critic in 1835 which he was to carry on steadily in various magazines till the end. His keen and sound judgment as appraiser of contemporary literature, his idealism and musical gift as a poet, his weirdness and dramatic power as a storyteller, though hardly appreciated in his lifetime, have secured him today a prominent place among universally known men of letters. The complex and elusive nature of his productions can best be understood when one tries to seize the relations of his personality to the working of his mind.

The outstanding fact in Poe's character is a strange duality. We find this trait in his temper, in his mind, in his art. The wide divergence of contemporary judgments on the man seems to point to the coexistence in him of two persons. With those he loved and who saw him in repose, he was gentle, affectionate, obliging and devoted. Others, who were the butt of his sharp criticism or who happened to meet him in moments of excitement, found him irritable, arrogant, self-centred, sombre, rebellious, and went so far as to accuse him of lack of principle and conscience. Was it, in the latter case, a double of the man rising from harrowings

from appalling graveyard hallucinations, that ominously loomed through the gentler Poe's unstable being?

If we consider the mind of Poe, the duality is still more striking. On one side he was an idealist and a visionary. His yearning for the ideal was both of the heart and of the imagination. His sensitiveness to the beauty, purity and loveliness of woman, associated with the contemplation of her amid the sweetest objects of nature or in the glory of ethereal radiance, inspired him with his most touching lyrics ("To Helen," "The Sleeper," "Eulalie," "To One in Paradise"), and with the full-toned prose hymns to beauty and love in "Ligeia" and "Eleonora." His imagination carried him away from the earth and the material world into the angels' dwelling-place ("Israel"), into fairyland or dreamland, or into the empyrean, where souls dwell in immortality, where Monos and Una, Eros and Charmon, Oinos and Agathos hold discourses on the secrets of life and death, and whither the prophet of "Eureka" takes his flight to meditate on ultimate causes.

This Pythian mood was especially characteristic of the later years of his life. More generally, either in his verse ("Valley of Unrest," "Lenore," "The Raven," "For Anzu," "Ulalume") or in his prose-tales, his familiar mode of evasion from the universe of common experience was through converse with death-in-life or life-in-death, and through haunting thoughts, impulses, or fears that seem to belong to an eerie world of horrible dreams, lurking in his abnormal subliminal consciousness. From these materials he drew the startling effects of his "tales of death" ("House of Usher," "Red Death," "Valdemar," "Premature Burial," "Oval Portrait," "Shadow"), of his "tales of wickedness and crime" ("Berenice," "Black Cat," "William Wilson," "Imp of the Perverse," "Cask of Amontillado," "Tell-Tale Heart"), of his "tales of survival after dissolution" ("Ligeia," "Morella," "Metzengerstein"), and of his "tales of fatality" ("Assignment," "Man of the Crowd"). Even when he does not hurl his characters into the clutch of fearful, mysterious or supernal forces or on to the untrodden paths of the beyond, he uses the anguish of imminent death as the means of causing the nerves to quiver and the flesh to creep ("Pit and the Pendulum"), and his very grotesque inventions deal with corpses and decay in an uncanny play with the aftermath of death.

On the other side, Poe is conspicuous for a close observation of minute details, which characterizes the realist or the painter of *ironpe-voil* landscapes or familiar scenes. He resorts to this gift of precise, Defoe-like apprehension in the long narratives and in many of the descriptions that introduce the tales or constitute their setting. Closely connected with this accurate scanning of actual or imagined things, is his power of ratiocination. He prided himself on his faultless logic and he carefully handled this real accomplishment so as to impress the public with his possessing still more of it than he had. Hence the would-be feats of thought-reading, problem-unravelling and cryptography which he attributed to his Legrand and his Dupin. This suggested to him the "analytical tales," which introduced into literature the detective story, and his "tales of pseudo-science."

The same duality is evinced in his art. He was capable of writing angelic or weird poetry with a supreme sense of rhythm and word-appeal, or prose of sumptuous beauty and suggestiveness, with the apparent abandon of compelling inspiration; and he would write down a problem of morbid psychology or the outlines of an unrelenting plot in a hard and dry style, with the clear-cut directness of algebraic reasoning. He was capable of throwing massively into a poem or a prose-tale the most impressive unity of effect, as if urged by a flashing vision or an irresistible creative impulse; and he would disrobe in cold blood that seemingly unanalysable whole and show by precept and rule that it was the result of the most deliberate and artificial technique. In Poe's masterpieces, the double contents of his temper, of his mind and of his art are fused into a oneness of tone, structure and movement, the more effective, perhaps, as it is compounded of various elements that give depth and intensity to the total shewn or dismal glow.

Poe's genius was first recognized abroad. None did more to

persuade the world, and, in the long run, America, of Poe's greatness than Baudelaire and Mallarmé. The one was a romanticist and the other a symbolist; they hailed Poe as the wizard of letters who had had intimation of immortal truths and the divine faculty of calling up an other-worldly thrill. Even if the present and the future generations are less likely to tremble in awe at Poe's would-be revelations of Elysian or Tartarian lore, they will concur with his "discoverers" in admiring his fecund and startling invention, his exact dosage of artifice and spontaneity, and his supreme artistry.

Poe's works have been edited by J. A. Harnson (1903, containing biography and letters), and by E. C. Stedman and G. C. Woodberry (1914, with a memoir, biography and criticism).

Maclair, *Le génie d'Edgar Poe* (1925); H. Allen, *Israel* (1926); M. E. Phillips, *Edgar Allan Poe* (1926); J. W. Krutch, *Edgar Allan Poe* (1926). (C. C.)

POELZIG, HANS (1869-1936), German architect, was born in Berlin on April 30, 1869. He studied architecture at the Berlin Technische Hochschule and was subsequently director of the Breslau academy of arts (1903-16). He was city architect of Dresden from 1916 to 1920, and also an honorary professor at the Technische Hochschule there. In 1920 he started an advanced atelier for applied arts at the Berlin academy of arts. From 1924 to 1935 he was also professor of the architectural faculty of the Berlin Technische Hochschule. With the architect Peter Behrens (1868-1938), Poelzig was a pioneer of the German industrial-art movement. He was president of the Deutscher Werkbund, an association of progressive architects, designers and industrialists founded in 1907. Poelzig, like Behrens, was much concerned with freeing buildings from all superficial mannaisms thus his sulphur factory (1912) at Luban (Luban), Pol, was a group of purely functional block-shapes and the façade of the Berlin radio building (Funkhaus) of the late 1920s was virtually a great expanse of smooth wall pierced by well-balanced ranges of simple windows. However, he was also responsible for the remarkably decorated Grosses Schauspielhaus, Berlin, which he converted for Max Reinhardt from the old Schumann circus building. Poelzig died on June 14, 1936.

See Th. Haus, *Hans Poelzig* (1948).

POERIO, ALESSANDRO (1802-1848), Italian poet and patriot, was descended from an old Calabrian family, his father, Baron Giuseppe Poerio, being a distinguished Neapolitan lawyer. In 1815 he and his brother Carlo accompanied their father, who had been identified with Murat's cause, into exile, and settled at Florence. In 1818 they were allowed to return to Naples. Alessandro fought as a volunteer, under Guglielmo Pepe (*q.v.*), against the Austrians in 1817, but when the latter reoccupied Naples and the king abolished the constitution, the family was again exiled and settled at Gratz. Alessandro studied in Germany, and at Weimar he became the friend of Goethe. In 1835 the Poerios returned to Naples. In 1838 Alessandro accompanied Pepe as a volunteer to fight the Austrians in northern Italy, and on the recall of the Neapolitan contingent he followed Pepe to Venice. He was severely wounded in the fighting round Mestre, and died on Nov. 3, 1848. His poetry "reveals the idealism of a tender and delicate mind"; but he could also sound the clarion note of patriotism, as in his stirring poem *Il Risorgimento*.

His brother Carlo (1803-67), after returning to Naples, practised as an advocate, and from 1837 to 1848 was frequently arrested and imprisoned. Under the short lived constitution of 1848 he was minister of education. He resigned office in April and took his seat in parliament, where he led the constitutional opposition. After the Austrian victory Poerio was arrested (July 19, 1849) tried, and condemned to 19 years in irons. Chained in pairs, he and other political prisoners were confined in one small room in the bagno di Nisida, near the lazaretto. The exposure (1851) of the horrors of the Neapolitan dungeons by Gladstone, who emphasized especially the case of Poerio, awakened the indignation of Europe, but he was not released till 1858. He and other exiles were then placed on board a ship bound for the UNITED STATES, but the son of Settembrini, another of the

exiles, who was on board in disguise, compelled the crew to land them at Cork, whence Poerio made his way to London. In the following year he returned to Italy, and in 1860 he was elected deputy to the parliament of Turin, of which he was chosen vice-president in 1861. He died at Florence on April 28, 1867.

See Baldachini, *Della Vita e dei tempi di Carlo Poerio* (1867); W. E. Gladstone, *Two Letters to the Earl of Aberdeen* (1881); *Carlo Poerio and the Neapolitan Poets* (1888); Vannucci, *I Martiri della libertà italiana*, vol. II (Milan, 1880); Imbrani, *Alessandro Poerio a Venezia* (Naples, 1884); Del Giudice, *I Fratelli Poerio* (Turin, 1899); Countess Martignago Cesaresco, *Italian Characters* (1901).

POET LAUREATE. The laurel (*Lat. laurea*) was sacred to Apollo, and as such was used to form a crown or wreath of honour for poets and heroes. The word "laureate" or "laureated" thus came in English to signify eminent, or associated with glory, literary or military. "Laureate letters" in old times meant the despatches announcing a victory, and the epithet was given, even officially (e.g., to John Skelton) by universities, to distinguished poets. The term "poet laureate" was ultimately restricted to the office of the poet attached to the royal household, first held by Ben Jonson, for whom the position was, in its essentials, created by James I in 1617 (Jonson's appointment does not seem to have been formally made as poet-laureate, but his position was equivalent to that). The office was really a development of the practice of earlier times, when minstrels and versifiers were part of the retinue of the king, it is recorded that Richard Coeur de Lion had a *versificator regis* (Gulielmus Peregrinus), and Henry III. had a *versificator* (Master Henry); in the 15th century John Kay, also a "versifier," described himself as Edward IV's "humble poet laureate." Moreover, the Crown had shown its patronage in various ways, Chaucer had been given a pension and a perquisite of wine by Edward III., and Spenser a pension by Queen Elizabeth. Sir William Davenant succeeded Jonson in 1638, and the title of poet laureate was conferred by letters patent on Dryden in 1670, two years after Davenant's death, coupled with a pension of £300 and a butt of Canary wine. This was the beginning of the official laureateship. The successors of Dryden were T. Shadwell (who originated annual birthday and new year odes), Nahum Tate, Nicholas Rowe, Laurence Eusden, Colley Cibber, William Whitehead, Thomas Warton, H. J. Pye, Southey, Wordsworth, Tennyson, Alfred Austin, Robert Bridges (appointed 1913) and John Masefield (appointed 1930).

The poet laureate, being a court official, was considered responsible for producing formal and appropriate verses on birthdays and state occasions. Wordsworth stipulated before accepting the honour, that no formal effusions from him should be considered a necessity; but Tennyson was generally happy in his numerous poems of this class. The emoluments of the post have varied. To Pye an allowance of £27 was made instead of the Canary wine. Tennyson drew £22 a year, and £27 in lieu of the "butt of sack."

See Walter Hamilton, *Poets Laureate of England* (1879), and E. K. Broadus, *The Laureateship* (1921).

POETRY. In modern criticism the word poetry (*i.e.* the art of the poet, Gr. *ποίησις*, maker, from *ποιέω*, to make) is used sometimes to denote any expression (artistic or other) of imaginative feeling, sometimes to designate a precise literary art, which ranks as one of the fine arts. As an expression of imaginative feeling, as the movement of an energy, as one of those great primal human forces which go to the development of the race, poetry in the wide sense has played as important a part as science. In some literatures (such as that of England) poetic energy, and in others (such as that of Rome) poetic art is the dominant quality. It is the same with individual writers. In classical literature Pindar may perhaps be taken as a type of the poets of energy; Virgil of the poets of art. With all his wealth of poetic art Pindar's mastery over symmetrical methods never taught him to "sow with the hand," as Corinna declared, while his poetic energy always impelled him to "sow with the whole sack."

In some writers, and these the very greatest—in Homer, Aeschylus, Sophocles, Dante, Shakespeare, Milton, and perhaps Goethe—poetic energy and poetic art are seen in something like equipoise. It is of poetry as an art, however, that we have mainly

to speak here, and all that we have to say upon poetry as an energy is that the critic who, like Aristotle, takes this wide view of poetry—the critic, who, like him, recognizes the importance of poetry in its relations to man's other expression of spiritual force, claims a place in point of true critical sagacity above that of a critic, who, like Plato, fails to recognize that importance.

With regard to poetry as an art, most of the great poems of the world are dealt with elsewhere in this work, either in connection with the names of the writers or with the various literatures to which they belong, consequently, these remarks must be confined to general principles. Under Verse the detailed questions of prosody are considered here we are concerned with the essential principles which underlie the meaning of poetry as such.

All that can be attempted is to inquire.

(1) What is poetry?

(2) What varieties of poetic art are the outcome of the two great kinds of poetic impulse, dramatic imagination, and lyric or egoistic imagination?

Definition of Poetry.—Definitions are for the most part alike unsatisfactory and treacherous, but definitions of poetry are proverbially so. Yet some definition must be here attempted, and, using the phrase "absolute poetry" as the musical critics use the phrase "absolute music," we may, perhaps, without too great presumption submit the following.

Absolute poetry is the concrete and artistic expression of the human mind in emotional and rhythmical language.

This, at least, will be granted, that no literary expression can, properly speaking, be called poetry that is not in a certain deep sense emotional, whatever may be its subject-matter, concrete in its method and its diction, rhythmical in movement, and artistic in form.

That the expression of all real poetry must be concrete in method and diction is obvious, and yet this dictum would exclude from the definition much of what is called didactic poetry. With abstractions the poet has nothing to do, save to take them and turn them into concretions, for, as artist, he is simply the man who by instinct embodies in concrete forms that "universal idea" which Gravina speaks of—that which is essential and elemental in nature and in man; as poetic artist he is simply the man who by instinct chooses for his concrete forms metrical language.

As an example of the absence of concrete form in verse take the following lines from George Eliot's *Spanish Gypsy*:

"Speech is but broken light upon the depth
Of the unspoken, even your loved words
Float in the larger meaning of your voice
As something dimmer."

Without discussing the question of blank verse cadence and the weakness of a line where the main accent falls upon a positive hiatus, "of the unspoken," we would point out that this powerful passage shows the spirit of poetry without its concrete form. The abstract method is substituted for the concrete. Such an abstract phrase as "the unspoken" belongs entirely to prose.

That poetry must be metrical or even rhythmical in movement, however, is what some have denied. Here we touch at once the very root of the subject. Aristotle seems to have assumed that the indispensable basis of poetry is invention; and perhaps the first critic who tacitly revolted against the dictum that substance, and not form, is the indispensable basis of poetry was Dionysius of Halicarnassus, whose treatise upon the arrangement of words is really a very fine piece of literary criticism.

By the poets themselves metre was for long considered to be the one indispensable requisite of a poem, though, as regards criticism, even in the time of the appearance of the *Waverley Novels*, the *Quarterly Review* would sometimes speak of them as "poems"; and perhaps even later the same might be said of romances so concrete in method and diction, and so full of poetic energy, as *Wuthering Heights* and *Jane Eyre*, where we get absolutely all that Aristotle requires for a poem. However, at all events this at least may be said, that the division between poetical critics is not now between Aristotelians and others; it is of a different kind altogether. While one group of critics may still perhaps say with Dryden that "a poet is a maker, as the

name signifies" and that "he who cannot make (that is, invent) has his name for nothing," another group contends that it is not the invention but the artistic treatment, the form, which determines whether an imaginative writer is a poet or, a writer of prose—contends, in short, that emotion is the basis of all true poetic expression, whatever be the subject-matter, that thoughts must be expressed in an emotional manner before they can be brought into poetry, and that this emotive expression demands even yet something else, viz., style and form.

Although many critics are now agreed that "L'art est une forme," that without metre and without form there can be no poetry, there are few who would contend that poetry can exist by virtue of any one of these alone, or even by virtue of all these combined. Quite independent of verbal melody, though mostly accompanying it, and quite independent of "composition" there is an atmosphere floating around the poet through which he sees everything, an atmosphere which stamps his utterances as poetry. This atmosphere is what we call *poetic imagination*.

In order to produce poetry the soul must for the time being have reached that state of exaltation, that state of freedom from self-consciousness, depicted in the lines—

"I started once, or seemed to start, in pain
Resolved on noble things, and strove to speak
As when a great thought strikes along the brain
And flushes all the cheek."

Whatsoever may be the poet's "knowledge of his art" into this mood he must always pass before he can write a truly poetic line. For, notwithstanding all that may be said upon poetry as a fine art, it is in the deepest sense of the word an "inspiration." No man can write a line of genuine poetry without having been "born again" (or as the true rendering of the text says, "born from above"), and then the mastery over those highest reaches of form which are beyond the ken of the mere versifier comes to him as a result of the change.

It might almost be said, indeed, that Sincerity and Conscience, the two angels that bring to the poet the wonders of the poetic dream, bring him also the deepest, truest delight of form. It might almost be said that by aid of sincerity and conscience the poet is enabled to see more clearly than other men the eternal limits of his own art—to see with Sophocles that nothing, not even poetry itself, is of any worth to man, invested as he is by the whole army of evil, unless it is in the deepest and highest sense good, unless it comes linking us all together by closer bonds of sympathy and pity, strengthening us to fight the foes with whom Fate and even Nature, the mother who bore us, sometimes seem in league—to see with Milton that the high passion which in English is called love is lovelier than all art, lovelier than all the marble Mercuries that "await the chisel of the sculptor" in all the marble hills.

Varieties of Poetic Art.—We have now reached the inquiry: What varieties of poetic art are the outcome of the two kinds of poetic impulse, dramatic imagination and lyric or egotistic imagination? Allowing for all the potency of external influences, we shall not be wrong in saying that of poetic imagination there are two distinct kinds—(1) the kind of poetic imagination seen at its highest in Aeschylus, Sophocles, Shakespeare, and Homer, and (2) the kind of poetic imagination seen at its highest in Pindar, Dante, and Milton, or else in Sappho, Heine, and Shelley. The former, being in its highest dramatic exercise unconditioned by the personal or lyrical impulse of the poet, might perhaps be called *absolute* dramatic vision, the latter, being more or less conditioned by the personal or lyrical impulse of the poet, might be called *relative* dramatic vision. It seems impossible to classify poets, or to classify the different varieties of poetry, without drawing some such distinction as this, whatever words of definition we may choose to adopt.

For the achievement of all pure lyric poetry such as the ode, the song, the elegy, the idyll, the sonnet, the stornello, it is evi-

dent that the imaginative force we have called *relative vision* will suffice. And if we consider the matter thoroughly, in many other forms of poetic art—forms which at first sight might seem to require absolute vision—we shall find nothing but *relative vision* at work.

Even in Dante, and even in Milton and Virgil, it might be difficult to trace the working of any other than *relative vision*. And as to the entire body of Asiatic poets, it might perhaps be found (even in view of the Indian drama) that *relative vision* suffices to do all their work. Indeed the temper which produces true drama is, it might almost be said, a growth of the Western mind. For, unless it be Semitic, as seen in the dramatic narratives of the Bible, or Chinese, as seen in that remarkable prose story *The Two Fair Cousins* translated by Rémusat, absolute vision seems to have but small place in the literatures of Asia. The wonderfulness of the world and the romantic possibilities of fate or circumstance, or chance—not the wonderfulness of the character to whom these possibilities befall—are ever present to the mind of the Asiatic poet. It was left for the poets of Europe to show that, given the interesting character, given the Achilles, the Odysseus, the Helen, the Priam, any adventure happening to such a character becomes interesting.

What then is this absolute vision, this true dramatic imagination which can hardly be found in Asia—which even in Europe cannot be found except in rare cases? Between *relative* and *absolute vision* the difference seems to be this, that the former only enables the poet, even in its very highest exercise, to make his own individuality, or else humanity as represented by his own individuality, live in the imagined situation, the latter enables him in its highest exercise to make special individual characters other than the poet's own life in the imagined situation.

"That which exists in nature," says Hegel, "is a something purely individual and particular. Art, on the contrary, is essentially destined to manifest the general." And no doubt this is true as regards the plastic arts, and true also as regards literary art, save in the very highest reaches of pure drama and pure lyric, when it seems to become art no longer—when it seems to become the very voice of Nature herself. The cry of Priam when he puts to his lips the hand that slew his son is not merely the cry of a bereaved and aged parent, it is the cry of the individual king of Troy, and expresses above everything else that most naive, pathetic, and winsome character. Put the words into the mouth of the irascible and passionate Lear and they would be entirely out of keeping.

Lyric, Epic, and Dramatic Singers.—It may be said then that, while the poet of *relative vision*, even in its very highest exercise, can only, when depicting the external world, deal with the general, the poet of *absolute vision* can compete with Nature herself and deal with both general and particular. If this is really so, we may perhaps find a basis for a classification of poetry and of poets. That all poets must be singers has already been maintained. But singers seem to be divisible into three classes: first the pure *lyrists*, each of whom can with his one voice sing only one tune; secondly the *epic poets*, save Homer, the bulk of the narrative poets, and the quasi-dramatists, each of whom can with his one voice sing several tunes; and thirdly the true dramatists, who, having like the nightingale of Gongora many tongues, can sing all tunes.

It is to the first-named of these classes that most poets belong. With regard to the second class there are not of course many poets left for it, the first absorbs so many. But, when we come to consider that among those who, with each his one voice, can sing many tunes are Pindar, Firdausi, Jami, Virgil, Dante, Milton, Spenser, Goethe, Byron, Coleridge, Shelley, Keats, Schiller, Victor Hugo, the second class is so various that no generalization save such a broad one as ours could embrace its members. And now we come to class three, and must pause. The third class is necessarily very small. In it can only be placed such names as Shakespeare, Aeschylus, Sophocles, Homer, and (hardly) Chaucer.

These three kinds of poets represent three totally different kinds of poetic activity.

With regard to the first, the pure *lyrists*, the impulse is mere

egocism Many of them have less of even relative vision at its highest than the mass of mankind They are often too much engaged with the emotions within to have any deep sympathy with the life around them Of every poet of this class it may be said that his mind to him "is kingdom is" and that the smaller the poet the bigger to him is that kingdom To make use of a homely image—like the chaffinch whose eyes have been pricked by the bird-fancier, the pure lyricist is sometimes a warbler because he is blind Still, he feels that the Muse loves him exceedingly She takes away his eyesight, but she gives him sweet song And his song is very sweet, very sad, and very beautiful, but it is all about the world within his own soul—its sorrows, joys, fears, and aspirations

With regard to the second class the impulse here is no doubt a kind of egocism too, yet the poets of this class are all of a different temper from the pure lyricists They have a wide imagination, but it is still relative, still egocistic They have splendid eyes, but eyes that never get beyond seeing general, universal humanity (typified by themselves) in the imagined situation Not even to these is it given to break through that law of centrality by which every "me" feels itself to be the central "me"—the only "me" of the universe, round which all other spurious "me's" revolve This "me" of theirs they can transmute into many shapes, but they cannot create other "me's"—nay, for egocism, some of them scarcely would, perhaps, if they could

The third class, the true dramatists, whose impulse is the simple yearning to create akin to that which made "the great Vishnu yearn to create a world," are, "of imagination all compact"—so much so that when at work "the divinity" which Iamblichus speaks of "seizes for the time the soul and guides it as he will"

The distinction between the pure lyricists and the other two classes of poets is obvious enough But the distinction between the quasi-dramatists and the pure dramatists requires a word of explanation before we proceed to touch upon the various kinds of poetry that spring from the exercise of relative and absolute vision Sometimes, to be sure, the vision of the true dramatists—the greatest dramatists—will suddenly become narrowed and obscured, as in that part of the *Oedipus Tyrannus* where Sophocles makes Oedipus ignorant of what every one in Thebes must have known, the murder of Laius And again, finely as Sophocles has conceived the character of Electra, he makes her, in her dispute with Chrysothemis, give expression to sentiments that, in another play of his own, come far more appropriately from the lofty character of Antigone in a parallel dispute with Ismene And, on the other hand, examples of relative vision in its furthest reaches can be found in abundance everywhere, especially in Virgil, Dante, Calderon, and Milton

In Coleridge's "Ancient Mariner" we find an immense amount of relative vision of so high a kind that at first it seems absolute vision When the ancient mariner, in his narrative to the wedding guest, reaches the slaying of the albatross, he stops, he can proceed no farther, and the wedding guest exclaims:—

"God save thee, Ancient Mariner,
From the fiends that plague thee thus!
Why look'st thou so?" "With my cross-bow
I shot the albatross"

But there are instances of relative vision—especially in the great master of absolute vision, Shakespeare—which are higher still—so high indeed that not to relegate them to absolute vision seems at first sight pedantic Such an example is the famous speech of Lady Macbeth in the second act, where she says:—

"Had he not resembled
My father as he slept, I had don't"

Marvellously subtle as is this speech it will be found, if analysed, that it expresses the general human soul rather than any one special human soul Indeed, Leigh Hunt records the case of a bargeman who, charged with robbing a sleeping traveller in his barge, used in his confession almost identical words—"Had he not looked like my father as he slept, I should have killed as well as robbed him." Again, the thousand-and-one cases (to be found in every literature) where a character, overwhelmed by some

sudden surprise or terror, asks whether the action going on is that of a dream or of real life, must all, on severe analysis, be classed under relative rather than under absolute vision—even such a fine speech, for instance, as that where Pericles, on discovering Marina, exclaims—

"This is the rarest dream that e'er dull sleep
Did mock sad fools withal"

even here, we say, the humanity rendered is general and not particular, the vision at work is relative and not absolute The poet, as representing the whole human race, throwing himself into the imagined situation gives us what general humanity would have thought, felt, said, or done in that situation, not what one particular individual and he alone would have thought, felt, said, or done

Now what we have called absolute vision operates in a very different way So vividly is the poet's mere creative instinct at work that the *ego* sinks into passivity—becomes insensitive to all impressions other than those dictated by the vision—by the "divinity" which has "seized the soul." Shakespeare is full of examples Take the scene in the first act of *Hamlet*, where Hamlet hears for the first time, from Horatio, that his father's ghost haunts the castle Having by short sharp questions elicited the salient facts attending the apparition, Hamlet says, "I would I had been there" To this Horatio makes the very commonplace reply, "It would have much amazed you" Note the marvellously dramatic reply of Hamlet—"Very like, very like! Stayed it long?" Suppose that this dialogue had been attempted by any other poet than a true dramatist, or by a true dramatist in any other mood than his very highest, Hamlet, on hearing Horatio's commonplace remarks upon phenomena which to Hamlet were more subversive of the very order of the universe than if a dozen stars had fallen from their courses, would have burst out with "Amazed me!" and then would have followed an eloquent declamation about the "amazing" nature of the phenomena and their effect upon him But so entirely has the poet become Hamlet, so completely has "the divinity seized his soul," that all language seems equally weak for expressing the turbulence within the soul of the character, and Hamlet exclaims in a sort of meditative irony, "Very like, very like!" It is exactly this one man Hamlet, and no other man, who in this situation would have so expressed himself.

While all other forms of poetic art can be vitalized by relative vision, there are two forms (and these the greatest) in which absolute vision is demanded, viz, the drama, and in a lesser degree the Greek epic, especially the *Iliad* This will be seen more plainly perhaps if we now vary our definitions and call relative vision *egocistic imagination*; absolute vision *dramatic imagination*.

The nature of this absolute vision or true dramatic imagination is easily seen if we compare the dramatic work of writers without absolute vision, such as Calderon, Goethe, Ben Jonson, Fletcher, and others, with the dramatic work of Aeschylus and of Shakespeare While of the former group it may be said that each poet skilfully works his imagination, of Aeschylus and Shakespeare it must be said that each in his highest dramatic mood does not work, but is worked by his imagination Note, for instance, how the character of Clytemnestra grows and glows under the hand of Aeschylus The poet of the *Oedipus* had distinctly said that Agasthus, her paramour, had struck the blow, but the dramatist having imagined the greatest tragic female in all poetry, finds it impossible to let a man like Agasthus assist such a woman in a homicide so daring and so momentous And when in that terrible speech of hers she justifies her crime (ostensibly to the outer world, but really to her own conscience), the way in which, by sheer magnetism of irresistible personality, she draws our sympathy to herself and her crime is unrivalled out of Shakespeare and not surpassed even there

Epic and Drama Compared.—Much has been said as to the scope of these. If in epic the poet has the power to take the imagination of his audience away from the dramatic centre and show what is going on at the other end of the great web of the world, he can do the same thing in drama by the chorus, and also

by the introduction into the dramatic circle of messengers and others from the outside world. But as regards epic poetry, is it right that we should hear, as we sometimes do hear, the voice of the poet himself as chorus bidding us contrast the present picture with other pictures afar off, in order to enforce its teaching and illustrate its pathos? This is a favourite method with modern poets and a still more favourite one with prose narrators. Does it not give an air of self-consciousness to poetry? Does it not disturb the intensity of the poetic vision? Yet it has the sanction of Homer, and who shall dare to challenge the methods of the great father of epic? An instance occurs in *Iliad* v. 58, where, in the midst of all the stress of fight, the poet leaves the dramatic action to tell us what became of the inheritance of Phaenops, after his two sons had been slain by Diomedes. Another instance occurs in iii. 243-244, where the poet, after Helen's pathetic mention of her brothers, comments on the cause of their absence, "criticizes life" in the approved modern way, generalizes upon the impotence of human intelligence—the impotence even of human love—to pierce the darkness in which the web of human fate is woven. Thus she spoke (the poet tells us), but the life-giving earth already possessed them, there in Lacedaemon, in their dear native land—

ὥς φάτο τοὺς δ' ἤθη κάτεχεν φωνίσσας αἶα
ἐν Λακεδαίμονι αἶδη, φίλῃ ἐν πατρίδι γαίῃ

This, of course, is "beautiful exceedingly," but, inasmuch as the imagination at work is egotistic or lyrical, not dramatic, inasmuch as the vision is relative, not absolute, it does not represent that epic strength which we call specially "Homeric."

The deepest of all the distinctions between dramatic and epic methods has relation, however, to the nature of the dialogue. Aristotle failed to point it out, and this is remarkable until we remember that his work is but a fragment of a great system of criticism. In epic poetry, and in all poetry that narrates, whether the poet be Homer, Chaucer, Thomas the Rhymer, Gottfried von Strassburg, or Turgidus, the action, of course, is moved partly by aid of narrative and partly by aid of dialogue, but in drama the dialogue has the quality of suggestiveness and subtle inference which we do not expect to find in any other poetic form save perhaps that of the purely dramatic ballad. In ancient drama this quality of suggestiveness and subtle inference is seen not only in the dialogue but in the choral odes. The third ode of the *Agamemnon* is an extreme case in point, where by a kind of *double entendre* the relations of Clytemnestra and Aegisthus are darkly alluded to under the cover of allusions to Paris and Helen. Of this dramatic subtlety Sophocles is perhaps the greatest master, and certain critics have been led to speak as though irony were the heart-thought of Sophoclean drama. But the suggestiveness of Sophocles is pathetic (as Professor Lewis Campbell well pointed out), not ironical. This is one reason why drama more than epic seems to satisfy the mere intellect of the reader, though this may be counterbalanced by the hardness of mechanical structure which sometimes disturbs the reader's imagination in tragedy.

The Lyric Imagination.—But we must now give undivided attention to pure egotistic or lyric imagination. This, as has been said, is sufficient to vitalize all forms of poetic art save drama and the Greek epic. It would be impossible to discuss adequately here the Hebrew poets, who have produced a lyric so different in kind from all other lyrics as to stand in a class by itself. As it is equal in importance to the Great Drama of Shakespeare, Aeschylus, and Sophocles, we may perhaps be allowed to call it the "Great Lyric." The Great Lyric must be religious—it must, it would seem, be an outpouring of the soul, not towards man, but towards God, like that of the God-intoxicated prophets and psalmists of Scripture. Even the lyric fire of Pindar owes much to the fact that he had a childlike belief in the myths to which so many of his contemporaries had begun to give a languid assent. But there is nothing in Pindar, or indeed elsewhere in Greek poetry, like the rapturous song, combining unconscious power with unconscious grace, which we have called the Great Lyric. It might perhaps be said indeed that the Great Lyric is purely Hebrew

But, although we could hardly expect to find it among those whose language, complex of syntax and alive with self-conscious inflexions, bespeaks the scientific knowings of the Western mind, to call the temper of the Great Lyric broadly "Asiatic" would be rash. It seems to belong as a birthright to those descendants of Shem, who, yearning always to look straight into the face of God and live, could (when the Great Lyric was sung) see not much else.

Though two of the artistic elements of the Great Lyric, unconsciousness and power, are no doubt plentiful enough in India, the element of grace is lacking for the most part. The Vedic hymns are both nebulous and unemotional, as compared with Semitic hymns. And as to the Persians, they, it would seem, have the grace always, the power often, but the unconsciousness almost never. This is inevitable if we consider for a moment the chief characteristic of the Persian imagination—an imagination whose wings are not so much "bright with beauty" as heavy with it—heavy as the wings of a golden pheasant—steeped in beauty like the "tiger-moth's deep damasked wings." Now beauty of this kind does not go to the making of the Great Lyric.

Then there comes that poetry which, being ethnologically Semitic, might be supposed to exhibit something at least of the Hebrew temper—the Arabian. But, whatever may be said of the oldest Arabic poetry, with its deep sense of fate and pain, it would seem that nothing can be more unlike than the Hebrew temper and the Arabian temper as seen in later poets. It is not with Hebrew but with Persian poetry that Arabian poetry can be usefully compared. If the wings of the Persian imagination are heavy with beauty, those of the later Arabian imagination are bright with beauty—brilliant as an Eastern butterfly, quick and agile as a dragon-fly or a humming-bird. To the eye of the Persian poet the hues of the earth are (as Firdausi says of the garden of Afrasiab) "like the tapestry of the kings of Ormuz, the air is perfumed with musk, and the waters of the brooks are the essence of roses." And to the later Arabian no less than to the Persian the earth is beautiful, but it is the clear and sparkling beauty of the earth, as she "wakes up to life, greeting the Sabaeen morning," we feel the light more than the colour. But it is neither the Persian's instinct for beauty nor the Arabian's quenchless wit and exhaustless animal spirits that go to the making of the Great Lyric; far from it. In a word, the Great Lyric, as we have said, cannot be assigned to the Asiatic temper generally any more than it can be assigned to the European temper.

The Ode.—In the poetry of Europe, if we cannot say of Pindar, devout as he is, that he produced the Great Lyric, what can we say of any other European poet? The truth is that, like the Great Drama, so straight and so warm does it seem to come from the heart of man in its highest moods that we scarcely feel it to be literature at all. Passing, however, from this supreme expression of lyrical imagination, we come to the artistic ode. Whatever may have been said to the contrary, enthusiasm is, in the nature of things, the very basis of the ode, for the ode is a mono-drama, the actor in which is the poet himself, and, as Marmontel has well pointed out, if the actor in the mono-drama is not affected by the sentiments he expresses, the ode must be cold and lifeless. But, although the ode is a natural poetic method of the poet considered as a prophet—although it is the voice of poetry as a fine frenzy—it must not be supposed that there is anything lawless in its structure. "Pindar," says the Italian critic, Gravina, "launches his verses upon the bosom of the sea, he spreads out all his sails; he confronts the tempest and the rocks; the waves arise and are ready to engulf him, already he has disappeared from the spectator's view, when suddenly he springs up in the midst of the waters and reaches happily the shore." Now it is this Pindaric discursiveness, this Pindaric unrestraint as to the matter, which has led poets to attempt to imitate him by adopting an unrestraint as to form. Although no two odes of Pindar exhibit the same metrical structure (the Aeolian and Lydian rhythms being mingled with the Doric in different proportions), yet each ode is in itself obedient, severely obedient, to structural law. This we feel, but what the law is

exactly no metrist has perhaps ever yet been able to explain

It was a strange misconception that led people for centuries to use the word "Pindaric" and irregular as synonymous terms; whereas the very essence of the odes of Pindar (of the few, alas! which survive to us) is their regularity. There is no more difficult form of poetry than this, and for this reason when in any poetical composition the metres are varied, there must be a reason for such freedom, and that reason is properly subjective—the varying form must embody and express the varying emotions of the singer. But when these metrical variations are governed by no subjective law at all, but by arbitrary rules, supposed to be evolved from the practice of Pindar, then that very variety which should aid the poet in expressing his emotion crystallizes it and makes the ode the most rigid of all compositions. Great as Pindar undoubtedly is, it is deeply to be regretted that no other poet survives to represent the triumphal ode of Greece—the digressions of his subject matter are so wide, and his volubility is so great.

The great difficulty of the English ode is that of preventing the apparent spontaneity of the impulse from being marred by the apparent artifice of the form, or, assuredly, no writer subsequent to Coleridge and to Keats would dream of writing an ode on the cold Horatian principles adopted by Warton, and even by Collins, in his beautiful "Ode to Evening."

Fervour being absolutely essential, we think, to a great English ode, fluidity of metrical movement can never be dispensed with. The more billowy the metrical waves the better suited are they to render the emotions expressed by the ode, as the reader will see by referring to Coleridge's "Ode to France" (the finest ode in the English language according to Shelley), and giving special attention to the first stanza—to the way in which the first metrical wave, after it has gently fallen at the end of the first quatrain, leaps up again on the double rhymes (which are expressly introduced for this effect), and goes bounding on, billow after billow, to the end of the stanza. Not that this fine ode is quite free from the great vice of the English ode, rhetoric. If we except Spenser, and in one instance Collins, it can hardly be said that any English writer before Shelley and Keats produced odes independent of rhetoric and supported by pure poetry alone. But fervid as are Shelley's "Ode to the West Wind" and Keats's odes "To a Nightingale" and "On a Grecian Urn" they are entirely free from rhetorical flavour. Notwithstanding that in the "Ode on a Grecian Urn" the first stanza does not match in rhyme arrangement with the others, while the second stanza of the "Ode to a Nightingale" varies from the rest by running on four rhyme-sounds instead of five, vexing the ear at first by disappointed expectation, these two odes are, after Coleridge's "France," the finest regular odes perhaps in the English language.

The main other varieties of lyrical poetry, such as the idyll, the satire, the ballad, the sonnet, etc., are treated in separate articles (T. W. D., X.)

MODERN DEVELOPMENTS IN BRITISH POETRY

This note purports only to deal with the principal developments of British verse in the 20th century. The difficulty, however, is to decide when that century began. We cannot, unhappily, for this purpose permit the composers of almanacs to settle the question. Something more subtle than arithmetic is at work. What we have actually to do is to isolate the moment at which Victorianism was definitely spent and something new was born. From that point of view an attempt will be made to show that the new period was precipitated not earlier than 1910 with the Georgians. Till then we are still in the spacious days of great Victoria.

The '90s were, of course, essentially Victorian, in the sense that every blind reaction is an integral part of that from which it reacts. The Rhymers' club was not that new way of saying "yes" which alone is the mark of a new movement. It was merely spinted contradiction, or even what we should now call a rather blatant exhibition of an inferiority-complex. When Arthur Symonds, for example, wrote his defence of the prostitute, with cock-robin self-consciousness, he was not so much shocking the suburbs as Lord Tennyson. When Ernest Dowson fainted prettily with

Pierrot, or invited Cynara to share his exquisite self-deprecation, he was not in fact languid or corrupt. He was protesting against the heartiness of Dickens and the incorruptibility of King Arthur. In that way a queer self-condemned poetry of artifice arose, which had its roots neither in life nor in the refusal of life, but in the rejection of the poet laureate. That, however amusing or lively, is not a broad enough basis for a new period of literature.

Poetry of the '90s.—Two objections may fairly be raised to this interpretation of the '90s. On the one hand the names of Robert Bridges, Thomas Hardy and Rudyard Kipling will be advanced as proving that at that time there was a volume of virile and important verse being written which was influenced neither by hating nor distaste for Victorianism. On the other hand, it will be pointed out that W. B. Yeats and A. E. Housman—two of the most considerable poets of our time—had both fully established themselves in the '90s. Having regard to the profound influence of *A Shropshire Lad* an objector might go so far as to claim that the 20th century began not in 1906 but ten years earlier in 1896.

Yet these objections, though serious, are not valid. In every period there are distinguished writers who do not influence, and are not influenced by their contemporaries in their sphere of creation. That is essentially true, though for different reasons, of Bridges, Hardy and Kipling. Robert Bridges in such a poem, for example, as "I have loved flowers" permanently enriched the English treasury. But it has that curiously withdrawn quality, that affinity to the grave unswerving mould of the classic, which distinguishes all his work. Both in his simplicity here, and his metrical experiments and complexities elsewhere, Bridges is neither Victorian nor post-Victorian. He contributes, but he neither borrows nor influences. So, too, with Hardy. That reluctant expression, that constant effect of breaking a chisel on obdurate stone, may be admired. It can never be imitated, and it is doubtful whether any one would seek to imitate it. Standards that apply to no other poet, and to no other poetry, have been applied to Hardy, and by those standards he has by some been adjudged triumphantly successful. But he has no disciples as he had no master. To some his poetry may stand out like Stonehenge in a great plain, and in these it will inspire awe and perhaps worship. But it will remain as rugged, as isolated, and to many as unmanageable as those great monoliths. Kipling again, though incomparably the most popular poet of his time, is not, and could not be, a poet's poet. In so far as he was a brilliant and sometimes vicious pamphleteer, he was bound to suffer the fate of all politicians. As the author of *Barrack Room Ballads* he created not so much a new school of verse as a new army, just as in his poems of empire he joined hands with Cecil Rhodes and Joseph Chamberlain, and turned his back on Parnassus. When he consented to be a poet, as in such a perfect lyric as the *Valour and Innocence* poem in *Rewards and Fairies*, he did not affect his fellow poets because they had been frightened away by the outcries of the imperial burcina. The small body of his real verse will be winnowed out by time from the great quantity of chaff, but its effect will not be felt till the separation is complete.

W. B. Yeats did start, or was an important part of, a new and fertile period. But it was an Irish and not an English period. It is indeed one of the curiosities of literature (and races) that the Celtic revival so little influenced poetry in the sister-island. Yeats, "A. E." and James Stephens affected the English hardly at all. It is, however, true that for Ireland the 20th century began in the '90s and what a century! Yeats and the Abbey Theatre, rather than all the politicians who spoke and died for Erin, were the fathers of the Revolution. Poets in Ireland always, more than elsewhere, have been recognized as

"the movers and shakers Of the world for ever"

Yeats wrote the first draft of the Constitution of the Free State in "The Lake-isle of Innisfree."

The answer to the objectors, therefore, remains. The typical poets of the '90s did not look forward eagerly, but backward contemptuously. They were not creating, they were for the most part sneering. The more considerable names either like Yeats belonged to Irish literature, or like the other three belonged to themselves only, or with Kipling to himself and certain echoes

overseas But there is still A. E. Housman In his case it is certain that he did profoundly influence his fellow writers, but it is more open to question whether it was not rather with the last enchantment of the old than with the first of the new age Perhaps Housman is no more than Robert Louis Stevenson signalling in vain from his Pacific island to the future. Because, though this has not been generally accepted, if at all, it is Stevenson in verse that was the most potent influence in the early part of the 20th century, and that influence was exerted in part at least through Housman, a disciple so unconscious of his master that he would certainly have repudiated him Yet the two are in essence the same—poets of comment and not of participation They have each a small neat explanation of the events they so competently, and sometimes so endearingly, describe The older man was the more human, the younger the better poet But Housman carried on the Stevenson note of deliberate interpretation with feeling introduced from without Housman attracted, and deserved to attract, general attention, but when his *Last Poems* was published in 1922 it became clear that he belonged to the world of Stevenson and not to ours His lads found the brook of the 20th century too broad for leaping They do not lie on the further side, but they stand there a little wistful and dim against a background of end-of-the-century self-consciousness They belong to the horizon whose margin fades behind us "for ever and for ever as we move"

Predecessors of the New Age.—Of the writers who carry over from the '90s to the first decade of the 20th century (for purposes of the almanac) none can be saluted even as the St John the Baptist of the New World Three at least deserve mention as writers of importance, though each must be denied the title of the forerunner—John Davidson, "Michael Field" and Stephen Phillips Of these Davidson in his baffled fury, his fundamental inability to clench with his hated antagonist because he never recognized him, is nearest to being the prophet He did not hate Victoria, or the Victorians He did not hate the gently anaemic Rhymers But what inspired his fits of temper, that sometimes rose almost into a genuine poetry of hate? Life, of course, but it is doubtful whether he ever knew exactly what in life it was that bit him Had it ever declared itself then Davidson might have set the trumpet of the herald to his mouth As it was, the instrument was something of a broken reed. "Michael Field" was the name chosen by those two remarkable women Katherine Bradley and Edith Cooper, aunt and niece, who composed their poems together For all their lovely cadence the verses never could have been more than a museum piece in a living world of letters Though there is in bulk a surprising quantity of their work, and though much of it will endure, yet even while it was written it had the air of a gracious antique It was a little as though those delicate fingers had discovered a lost art, and were, like Count Caloveghia in Norman Douglas' *South Wind*, moulding a faun with the enigmatic ecstasy of some disciple of Praxiteles Their best poems had an old and final ring.

Stephen Phillips is a very different case, and much more difficult to assess. In his poetic youth the fixed stars of poetry were crowded by the critics to give place to this new and larger luminary Within less than a quarter of a century he passed "unwept, unhonoured and unsung" So much so that when a posthumous play of his was published the writer who had undertaken the preface used it to indicate his author's remarkable shortcomings The truth about Stephen Phillips' rise and fall has not been told yet, and certainly the present estimate of his work is unfair to the writer who rediscovered the blank verse line. The rhetoric of *Herod* will disappear. It was inspired rather by Beer-bohm Tree than the terrarch But "Marpessa" will quietly and in due course climb to its modest place among the quieter candles of the night. For the purpose of this essay, however, Stephen Phillips is important because of the disappointment he provoked It was believed that the great tradition of English verse that Swinburne had for all his exotic beauty failed to renew, had returned The blank verse line is the most English and at its best the most decisive of metres. In Stephen Phillips it was hoped that it had resumed its old immortal mastery in a new prevailing way.

Stephen Phillips had some of the manner but none of the substance to restore the accent of the heroes He had a genuine singing impulse, and hands fit for a flute with two stops He was asked to play the organ in the Albert hall He should have been strong enough to refuse, but the blame attaches not a little to all the noisy pack of fawning critics who bayed him on to his doom Whoever's the fault, at least he left no mark on his successors.

They were pressing on At the very moment when the world was beginning to doubt its new idol, and in their doubt of him renewing their despair in poetry in general, the New Age was beginning in Oxford with a swarthy malcontent called James Flecker, at Cambridge with a group which Rupert Brooke led by unquestioned right, and outside Cambridge, but still in the polite world, with a certain Walter Ramal (Walter de la Mare) and a much less certain John Masefield, and outside the world altogether with W. H. Davies, who was not so much a man on the tramp as a bird on the wing But before all these gathering rivulets converged into the broad flood of Georgianism that forced its way ever widening into the threshold of World War I and, beyond it, strained and parcelled into the swamps of death, there were still the names of Herbert Trench, Sturge Moore, Henry Newbolt and Laurence Binyon, each with his individual claim and contribution. While roaring and laughing by their side, like two huge children in H. G. Wells's *Food of the Gods*, Hilaire Belloc and G. K. Chesterton shouted to each other across the world, and "when all church bells were silent, their caps and bells were heard"

It is perhaps not necessary to attempt to range the first three in this list Herbert Trench was a far from negligible poet, but he wrote in the grand manner at a time when events were conducting themselves in a manner at once small and obscene. His verse was too much a stranger to the times in which he lived ever to be at home there He speaks, therefore, always a little like a foreigner. Sturge Moore, also a poet of distinction, perhaps influenced his generation of writers more by his personality than his work, interesting and diverse as it is He has to his credit not merely a brilliant anthology of "Michael Field," but a solid body of mature and constructive criticism Henry Newbolt, who is at times unfairly bracketed with Alfred Noyes as a poet of "patriotism," has suffered by succeeding with his worst work "Drake's Drum" had (and continues to have) almost a music-hall success The result is that Newbolt has quite unfairly been classified as a minor Kipling—another partisan of the white man's beneficent destiny to take up his dividends But that is wholly unjust to a poet with a clear perception of realities, and an almost humble readiness to adapt his manner to his subject He came a little too early to belong to the new movement. If there had been no new movement his name would have stood very high Nor need we reclassify Hilaire Belloc and G. K. Chesterton They refused to be treated as grown-up poets They were Trinculo, Falstaff or Father Christmas in *The Christmas Carol*, and they deceived the world into believing them to be mere assassins They almost deceived themselves, but not quite Both, when they hated, wrote poetic satire unequalled since Pope, and Chesterton, at least, when he loved had a star hidden up his sleeve In vain he assured his audience to the contrary Why, his very words are on fire!

But Belloc and Chesterton stood outside the main stream of development, watching it as though two players in a football match should stand among the spectators applauding heartily In the circumstances it is difficult to accuse them of desertion it is better to take them for what they are—and to be thankful. We may turn from them to the players, who are thinking and who thought of nothing but the game

Georgian Poetry.—The name "Georgian poetry" was coined in the first anthology of contemporary poets published in 1911 under the editorship of Edward Marsh, to whom, and to Harold Monro the publisher of this and the subsequent volumes, modern British poetry owes much But the name is misleading, and has constantly misled critics It has been assumed that it represented a single school of writers with the same aim and the same method, much as were exhibited in the case of painting by the Pre-Raphaelites. This is in fact a quite false view. The contributors

to the Georgian volume—and to Georgian poetry—represented at least five divergent streams, their only link being a common passion for verse, and a common response to something in the age which was evoking it. Those who believe that the name is more than convenient shorthand may be asked to explain what community of aim and method are represented by de la Mare, Masfield, Hodgson, Drinkwater, Rupert Brooke, Flecker, Harold Monro, D. H. Lawrence and W. H. Davies, to name only nine of the leading figures in the revival. Can the dark Arabian musician mute his strings while Saul Kane is smashing a beer-bottle with a hammer? Would the Song of Honour be audible among the mild country sounds of the Cotswolds? How would the young men "into cleanness leaping" endure the doubtfully delicious neighbourhood of "Yasmun," and what would happen in Harold Monro's week-end cottage if two of D. H. Lawrence's lovers set about breaking up the eloquent crockery in the course of their noisily stark embraces? And would W. H. Davies's night-ingles sing through it all like choir boys when the organ's loud? The wealth and the strength of the period consists in its amazing diversity. It was the great achievement of Edward Marsh and Harold Monro to find a common meeting place for all these vigorous tendencies, but they had the wisdom to make no attempt to assimilate them.

It is difficult, if not impossible, to explain why one period rather than another should be rich in poetry. It is, for example, maintained that great verse generally coincides with some great national excitement, either of victory or defeat. Men sang, this view would maintain, best when they are most disturbed, and poetry, like trade, follows the battle-flag. This theory could easily be destroyed by instances both from England and France, and there is another theory which better explains the periods of fertility that supervene, as did the Georgian, on a long period of barrenness. It may perhaps be stated that poetry goes in long cycles for two reasons. First because it is the most intensive form of art. It is a divine shorthand, and can summarize in a page what may require a volume in prose. Poetry therefore is liable quickly to absorb its material. In the second place, though mankind never wants much poetry, it always demands a little. Poetry is in a sense the ultimate luxury of the human mind. It is a luxury that no men want all the time, few men want much of the time, but that all men must have some time. So great a need and so vast a desire do in the long run precipitate their object, and thus after silence song is born.

The Georgian period may have owed something to the stormy days in which it was generated. Imperialism had seen itself in the mirror of the Boer War and found that it looked uncommonly like a skeleton. Industrialism which for a century had been an affair of capital was with urgent creaks and groans becoming a problem of labour. Victorian comfort was changing into the lurid extravagance of Edwardianism. The oil-engine was challenging the printing-press for the control of the soul of man.

Here were conditions which called for examination, explanation, defence and condemnation, and if the prose-writers—Wells, Bennett, Galsworthy and Shaw—were at work, how and why should the poets be still? They weren't. But poetry is a subtler thing than prose. It is less like a photograph than a picture, less like a picture than a face seen by a lightning flash and remembered in a dream. Therefore it is not surprising that this grossly confused age should express itself supremely in a poet of sheer and airy music like Walter de la Mare, or in so consciously exquisite a craftsman as Flecker. These two with Masfield, Davies and Brooke stand out as the leading names of the period.

It is not our business to range as much as to record. The world was in fact brought to the realization of the re-birth of poetry not by Brooke, nor by the first Georgian anthology, nor by the publication of Flecker's *Bridge of Fire*, nor even by the establishment of the Poetry Bookshop in 1912. It was not to the marvel of *The Listeners* that the gates swung open, but to the huge hammer-blows of *The Everlasting Mercy* published in the *English Review*. The effect of that poem was almost comparable to the excitement induced by the appearance of *Don Juan*. Poetry with Masfield had once again ceased to be a matter for poets and

coteries: it had become the possession of the people.

By that one blow Masfield flung the door of public interest wide, and the rest of the waiting poets flooded through it with a shout. The period is so rich that in the first place there must be a catalogue of names like the Homeric catalogue of the ships—Lascelles Abercrombie, Gordon Bottomley, Rupert Brooke, W. H. Davies, John Drinkwater, F. S. Flint, John Freeman, Ralph Hodgson, W. W. Gibson, Gerald Gould, D. H. Lawrence, Walter de la Mare, Harold Monro, John Masfield, Thomas Goult, Charlotte Mew, Edward Shanks, Fredegond Shove, J. C. Squire, Anna Wickham, and of the Irish, W. B. Yeats, "A. E." James Stephens, Padraic Colum, Francis Ledwidge, Seumas O'Sullivan and Dr Douglas Hyde. And when it is recalled that all belong to the pre-War period, it is reasonable to suggest that Victorianism was dead, that a new and fertile period had begun. It is difficult to classify material so various, or in respect of work so recent to identify the prevailing influence, particularly as these influences are still working themselves out. Certain of these poets, it was clear from the outset, whatever their individual merits, would not be likely to found a school. Lascelles Abercrombie and Gordon Bottomley, for example, both engaged in revising the blank verse line and, if possible, in re-establishing the poetic drama, were necessarily monks of verse. With such preoccupations they would be bound to stand outside the main stream. Both added notably to the intensification of poetic language, and Bottomley in *Gruech* wrote a play in verse which in time will be recognized as a permanent part of British dramatic effort. But they were not likely to impinge on the work of their fellows. D. H. Lawrence, if a poet at all, was one so savagely individual, so arrogantly physical, that he must have abashed even his admirers. He reached the extreme of remorseless resignation to the senses. He might be endured; he could not be copied. Charlotte Mew, Fredegond Shove and Anna Wickham of the women all had their own self-centred emotions. In each case their output was limited to the altar of their spiritual nature. No other poets of their period reached such continuous intensity of expression, but its very merit made it fatiguing. They are all three poets whose poems should be lived with like a great picture rather than caught suddenly like the colour of a flower. Finally, of those not likely to fit into a scheme or to herald a new world those two distinguished poets Gerald Gould and Ralph Hodgson should be mentioned. Both were poets of discontent with their age. Gerald Gould carried into action what Ralph Hodgson immortalized expressed in such a poem as "The Gipsy Girl." But each had his own secret. Gould was on a pilgrimage; he was not sure whither, nor could he guide others. But he must seek. Ralph Hodgson of all his age saw loveliness most directly and strongly. He recorded it, and was struck dumb by the very completeness of his utterance.

These were then all poets who belonged to no school. But of the rest it might have been expected that de la Mare, Flecker or Masfield might each have set a fashion, though in fact it was Brooke who with Drinkwater and Harold Monro created that general attitude to which Freeman, Squire, Shanks and later Martin Armstrong, F. W. Harvey and Edmund Blunden attached themselves—the attitude to which the generic term "Georgian" has tended to be specifically applied. Of these in time Squire assumed the leadership, and he will be entitled to special memory if not as the founder at least as the saviour of a school of poetry.

De la Mare founded no school, though his rhythms have effected a profound revolution in the structure of English verse. No poet writing for the next 50 years will or can be unaffected by those fairy declensions, those elfin ascents. De la Mare need not fear mortality. His accent is now a part of English verse. He will continue to have imitators of his manner, but he is too incorrigibly delicate in substance to prevail upon the mind of other poets. Flecker perhaps failed of influence because of his long illness and untimely death. A poet cannot found a correspondence school, and Flecker, except for the earliest years of his output—the Oxford and Cambridge years—was first an exile in the East, and then a dying man in a Swiss sanatorium. It is, even so, surprising that "The Old Ships" should drag no lesser ships in their shining wake, or that no later pilgrims should have set out on "The

Golden Journey to Samarkand"

Effects of the War.—It is a question whether Masefield might not have created a school, if his violence had not been outpointed by the War. Strength and beauty, ranging hand in hand, were an intoxicating sight for all men, but most of all for poets. And it might have been supposed at least that Masefield would restore the narrative poem to its proper place in English poetry. He has not, and it is more than likely that the War, which encouraged pastoral poetry, the verse of retreat from uproar, may have equally turned men's minds from poetry, like Masefield's, of conflict and tumult.

However that may be, it is true that when war had with its usual foul impartiality murdered good and evil alike, it was to Brooke and the poets of release that the world for a moment turned. Brooke burst into fame with his War sonnets consecrated by his death in that Greek island. He became for the moment the expression of the youth of the world, gladly offering itself to wholesale assassination. But behind that momentary magnificence were the more enduring meadows of Grantchester. In these the wracked world might find peace. In these—or by the trees, whose whisper Freeman overheard, in the long wholesome stretches of Drinkwater's Cotswolds, by the harsher northern uplands of Wilfrid Gibson, in Harold Monro's most endearing consolation of the country cottage, or with the birds and the moon of Squire. This was a corporate offer to the world, and it was eagerly accepted.

For the moment. Because it was the habit of the War to make and break its idols almost simultaneously. Hardly had the new recruits flocked to the banner, hardly had Edward Shanks and Martin Armstrong added their conspiracy of release, when the poets of hatred burst upon the world like an angry shell. Robert Graves, Robert Nichols, Wilfred Owen, Siegfried Sassoon one after another blasted the romantic assumption that war was the consecration of youth by fire. In the teeth of a world staggering under its weight of stupid ugliness, these poets flung the single word "Murderers." The other poetry grew for the moment strangely dumb and pale. Men were listening to this new and abominable accusation—and even the fields, the birds and the moon could not distract them from it.

The name of Edward Thomas should be mentioned in this connection. Thomas was a much older man than the other poets here mentioned, and had written much before the War. But the War in some way released his response, and his reputation—growing and deserved—is wholly post-War. Because of the circumstances in which he wrote Thomas was entirely a poet for posterity. He could do nothing to arrest the doom of silence which the exhaustion of the War was suddenly to impose. Relentlessly this poison-gas of despair advanced till a period that had seemed to be most fertile since the Elizabethan, ended choking in the fog of the spirit that denies. By the end of the decade which had seen its origin Georgian poetry was spent, and the war poetry with it. Because it seemed that the poets, who had exposed its horrors and cursed its originators, were content to forget, or at least to live back into peace. Wilfred Owen was quiet, for ever, Robert Nichols turned to prose and play writing, Siegfried Sassoon at long intervals reminded the world of his genius. Only Robert Graves remained to write new forms of verse in the desperate hope of escaping from the memories he had permanently established in traditional shapes.

After the War.—And thereupon the silence smashed in 1910 began slowly to settle again. The Georgian period is over, and the war-period is over. There have been two later revolts, one known as "the Imagist" headed by F. S. Flint, with Transatlantic sanction, another led by Edith, Osbert and Sacheverell Sitwell. The first revolt like the poetry against which it protested has apparently ended. Flint, Richard Aldington and the Americans "H. D." and Ezra Pound, have contributed some ravishing melodies in free verse. They seem now to be replaced by verse not so much of freedom but in dissolution. They cannot compete, and they are wisely content to let the beauty they have made speak for itself. The Sitwell family on the other hand, and in a world of demal, affirm that with a slight shifting of the vision,

a little readjustment of values, living beauty can still be restored. At a time when verse was in active danger of dying of suffocation, they breathed new life into it. Their work at least is not dead.

For the rest of the most recent work there should be mentioned Edmund Blunden and Humbert Wolfe. Blunden, though associated with the Georgian school, has lived at first hand with his fields and his farms. To read him is not like paying a visit to the country but like living there. Humbert Wolfe attempted both satire and verse that is accused of a facile romanticism. His *Requiem* was in some quarters regarded as making an advance on his earlier work, but with him, as with the Sitwells, for the moment we must be content with saying that he continued the attack.

Two things have still to be said. Among the greatest of the names in contemporary poetry are the Irish poets, who have only been mentioned, but not discussed. That was for the reason given above, that Yeats created the new Irish poetry and had far less effect on purely English verse than Housman. But the body of English literature is one and indivisible, and though it is possible in the light of the strong impulse given by Yeats to see Irish verse of the century separately, it must at least be mentioned here. All of it, as it was bound to be, is informed by a passionate consciousness of Ireland. But if the matchless rhythms of Yeats turned back to legend for consolation and hope, if "A. E." plunged into a mysticism as profound as Blake's, though, unlike Blake's, regulated by a sweet humanity, James Stephens was already looking forward. He has found truth through laughter, the laughter of a thrush. He has probably more than the other two influenced the latest developments of Irish verse. Padraic Colum and Seumas O'Sullivan are not of the same order as these, though both are poets of distinction. Colum has the quiet dignity of the inspired peasant, while O'Sullivan writes in the immediate shadow of Yeats. There remain Francis Ledwidge, who died young after an early lyric promise of almost torturing loveliness, and Bertram Higgins and Austin Clarke who are going steadily forward in the paths laid down by Yeats and his peers.

(H. W. O. X.)

United States; Modern Developments.—Modern American poetry, characteristic of the 20th century, attempted a complete fusion of romanticism and realism. Carl Sandburg defined it as a "synthesis of hyacinths and biscuits." It was experimental and, to a large extent, anti-traditional. It sought to find fresh subject matter and unexploited material as opposed to "literary" conventions, it placed its emphasis on the local scene instead of on foreign or mythical regions; it cultivated a native idiom rather than the customary poetic diction. As early as the middle of the 19th century Walt Whitman had invited the Muse to migrate from Greece and Ionia, to "cross out those immensely overpaid accounts, that matter of Troy and Achilles' wrath, and Aeneas', Odysseus' wanderings," and turn from retrospections, recording proofs of the past, to the American continent—

For know a better, fresher, busier sphere, a wide, untrod domain awaits, demands you

Whitman and Emily Dickinson provided the way for the changes which followed. The pioneer vitalism of the former proclaimed a new force and unity through affirmation of the democratic spirit, the puritan mysticism of the latter achieved another kind of vigour which encouraged the use of daring metaphors and audacious turns of phrase. It took time to establish the new forces. The first edition of Whitman's *Leaves of Grass* was published in 1855 and Whitman prefaced a "deathbed edition" in 1891. Emily Dickinson's first posthumous volume was published in 1890, but no attempt at a biography of Emily Dickinson was written until 1924 and volumes of further unpublished poems kept appearing as late as 1935.

What has been called "the new era in American poetry" manifested itself suddenly in 1913. Edwin Markham's "The Man With the Hoe" had already struck the social conscience, but there was little to rouse the aesthetic consciousness. A number of small magazines devoted themselves exclusively to poetry; controversy was in the air, every month another new name was a signal for dispute which augmented the poetic "renaissance." *General Whitman Booth Enters Into Heaven* (1913) by Vachel Lindsay (1879—

1931) and *The Congo* (1914) brought excitement and a curiously syncretized music into verse, Lindsay's *Collected Poems* (1923) gave America its wide-swinging jazz in terms of literature. A missionary and evangelist at heart, Lindsay combined revivalism and ragtime, he preached the Gospel of Beauty through a saxophone.

Robert Frost's *A Boy's Will* appeared in England in 1913, but it was *North of Boston* (1914) which fully revealed Frost's union of playfulness with profundity and his gift for suggestive understatement. A restrained but distinctive tone of voice rose from all his subsequent work, six volumes of which were assembled in *Collected Poems* (1939), and showed him to be a farmer by circumstance, a philosopher by instinct, and a teacher by experience. Though his backgrounds were those of New England, his half-whimsical, half-sombre lyrics and monologues gave regionalism a universal amplitude and traditionalism a new direction.

The year 1914 marked the rise of free verse and the Imagist movement, a movement which recalled the program of the French Symbolists and which was divided between poetry and propaganda. Amy Lowell (1874-1925) was its militant champion, her own craftsmanship, at its best in *Selected Poems* (1928), preoccupied itself with enamelled images, vivid surfaces and the swiftly changing contours of the external world.

John Gould Fletcher, another Imagist, intensified motion with emotion, his *XXIV Elegies* (1935) are a far cry from the unrelated "colour symphonies" of *Goblins and Pagodas* (1916) "H D," who, with Ezra Pound, was one of the first Imagists, revealed a cumulative tensing beneath the stripped technique of her *Collected Poems* (1925). Edgar Lee Masters' *Spoon River Anthology* (1916) explored the limbo between prose and verse in a set of sociological epitaphs; its disillusioned gossip and documentation of the "small town" gave rise to a school of satire and self-criticism, of which Sinclair Lewis's *Main Street* (1920) was a prose counterpart.

The ranging impulses and far-flung creative energies extended throughout the country and into the mid-twenties. Edwin Arlington Robinson had been writing for years (his concise *Children of the Night* appeared as early as 1897), but *The Men Against the Sky* (1916) was the first of his characteristically astringent works to draw an audience which reached great numbers with *Tristram* (1927), his voluminous *Collected Poems* (1937) appeared two years after his death. Carl Sandburg first blended folk-stuff and fantasy, slang and mysticism in *Chicago Poems* (1916), his *The People, Yes* (1936) added national significance to the peculiar fusion. Edna St. Vincent Millay's remarkable *Renaissance* (1917) was succeeded by ten volumes which displayed her virtuosity and which, at the best, engagingly combined the voice of a precocious, eager child and the mind of an experienced, disillusioned woman. Her later work evoked varying degrees of enthusiasm; several critics deprecated the "destructive role of unofficial feminine laureate" which Miss Millay seemed called upon to assume in such collections as *Conversation at Midnight* (1937) and *Huntsman, What Quarry?* (1939). Sara Teasdale (1884-1933) became something of a vogue with *Reveries to the Sea* (1915), but the graver music of her *Dark of the Moon* (1926) was almost unnoticed. Elmer Wylie (1885-1928) strengthened the notes sounded by the contemporary singers, her lyrics and sonnets grew from the adroitness of *Nets to Catch the Wind* (1921) to the exaltation of the posthumously published *Angels and Earthly Creatures* (1929).

The strain of lyrical poetry was swelled by Léonie Adams, Louise Bogan, Genevieve Taggard, Jean Starr Untermeyer, and Dorothy Parker, whose wry flippancies were collected in *Not So Deep as a Well* (1936). A still more subtle music was registered in Conrad Aiken's *Selected Poems* (1929), in (or in spite of) the typographical oddities of E. E. Cummings, and in the modern ballads of William Rose Benét and Stephen Vincent Benét, whose *John Brown's Body* (1928) was panoramic in scope and epic in effect. Efforts to sound the "realistic" implications of the American scene were made by Kenneth Fearing, Muriel Rukeyser, and the pioneering William Carlos Williams, whose *Complete Collected Poems 1906-1938* were applauded alike by radicals and conservatives. Robinson Jeffers unleashed a violent, and often un-

controlled, power in a series of volumes from *Roan Stallion* (1926) to *Such Counsels You Gave to Me* (1938). Archibald MacLeish shaped words into surprisingly suspended cadences in *Poems 1924-1933*, fitted them into a new type of poetic drama in *Panic* (1935), put them to work on the radio and on the sound-track in *Land of the Free and Air Road* (1938).

A definite and seemingly determined attempt to join traditional metaphysical poetry with indigenous accents was expressed by a group calling itself "The Fugitives"; its leading exponents were John Crowe Ransom, Allen Tate, Donald Davidson and Robert Penn Warren. Their verse was alternately teasing and tortuous, the very richness of their allusive material made it difficult. Equally fascinating to the student and equally forbidding to the average reader were the abstract elegances of Wallace Stevens, the verbal legerdemain of Hart Crane, the crowded imagery of Horace Gregory, and the erudite intricacies of two celebrated expatriates Ezra Pound and T. S. Eliot. Eliot's work was the most considerable, it ranged from the baffled frustration of *Purloined and Other Poems* (1917) through the drought and disintegration of *The Waste Land* (1922) to the desperate faith of Eliot's later religious plays and essays. Finally there were the prodigies, notably Nathalia Crane, whose *The Janitor's Boy* (1924) was published when its author was not quite eleven, George Dillon, who won prizes in his teens and whose *Boy in the Wind* (1927) was published in his twenty-first year, and Merrill Moore, a psychiatrist, who wrote many of his poems in shorthand, and whose third volume, starkly entitled *M* (1938), contained 1,000 autobiographical sonnets (L. U.).

POEY Y ALOY, FELIPE (1799-1891), Cuban naturalist, was born in Havana on May 26, 1799. He received his degree in law at the University of Madrid (1820) but abandoned practice to devote himself to natural history. He returned to Cuba and formed a collection which he carried back to Paris. Here he remained until 1833, publishing many articles and his *Centurie de Lepidopteres de L'ile de Cuba* (1832). He became professor of zoology and comparative anatomy in the University of Havana in 1842 and in 1863 was appointed to the chair of botany, mineralogy and geology. From 1873 until his death at Havana on Jan. 28, 1891, he was professor of philosophy and belles lettres. His magnum opus is the *Catálogo razonado de los peces cubanos*, an atlas of ten volumes with over 1,000 of his own drawings, and describing about 800 tropical fish, about half of which he first made known to science.

POGGIO (1380-1459) Gian Francesco Poggio Bracciolini, Italian scholar of the Renaissance, was born in 1380 at Terranuova, a village in the territory of Florence. He studied Latin under John of Ravenna, and Greek under Manuel Chrysoloras. His distinguished abilities and his dexterity as a copyist of mss brought him into early notice with the chief scholars of Florence. Coluccio Salutati and Niccolò de' Niccoli befriended him, and in the year 1402 or 1403 he was received into the service of the Roman curia. His functions were those of a secretary; and, though he profited by benefices conferred on him in lieu of salary, he remained a layman to the end of his life. It is noticeable that, while he held his office in the curia through that momentous period of 50 years which witnessed the Councils of Constance and of Basle, and the final restoration of the papacy under Nicholas V, his sympathies were never attracted to ecclesiastical affairs. Nothing marks the secular attitude of the Italians at an epoch which decided the future course of both Renaissance and Reformation more strongly than the mundane proclivities of this apostolic secretary, heart and soul devoted to the resuscitation of classical studies amid conflicts of popes and antipopes, cardinals and councils, in all of which he bore an official part. Thus, when his duties called him to Constance in 1414, he employed his leisure in exploring the libraries of Swiss and Swabian convents. The treasures he brought to light at Reichenau, Weingarten, and above all St. Gall, restored many lost masterpieces of Latin literature, and supplied students with the texts of authors whose works had hitherto been accessible only in mutilated copies. In one of his epistles he describes how he recovered Quintilian, part of Valerius Flaccus, and the commentaries of Asconius Pedianus at St. Gall.

Manuscripts of Lucretius, Columella, Silius Italicus, Manilius and Vitruvius were unearthed, copied by his hand, and communicated to the learned. Wherever Poggio went he carried on the same industry of research. At Langres he discovered Cicero's *Orations*

for *Caecina*, at Modt Cassino a ms of Frontinus. He also could boast of having recovered Ammianus Marcellinus, Nonius Marcellus, Probus, Flavius Capet and Eutyches. If a codex could not be obtained by fair means, he was ready to use fraud, as when he bribed a monk to abstract a Livy and an Ammianus from the convent library of Hersfeld.

Poggio embraced the whole sphere of contemporary studies, and distinguished himself as an orator, a writer of rhetorical treatises, a panegyrist of the dead, a violent impugner of the living, a translator from the Greek, an epistolographer and grave historian and a facetious compiler of *fabliaux* in Latin. Of his moral essays it may suffice to notice the dissertations *On Nobility*, *On Vicissitudes of Fortune*, *On the Misery of Human Life*, *On the Infelicity of Princes* and *On Marriage in Old Age*. These compositions belonged to a species which, since Petrarch set the fashion, were very popular among Italian scholars. They have lost their value, except for the few matters of fact which are embedded in a mass of commonplace meditation, and for occasional brilliant illustrations.

Poggio's *History of Florence*, written in avowed imitation of Livy's manner, requires separate mention, since it exemplifies by its defects the weakness of that merely stylistic treatment which deprived so much of Brunetti, Carlo Aretino and Bembo's work of historical weight. A somewhat different criticism must be passed on the *Facetiae*, a collection of humorous and indecent tales expressed in such Latin as Poggio could command. This book is chiefly remarkable for its unsparing satires on the monastic orders and the secular clergy.

Among his contemporaries Poggio passed for one of the most formidable polemical or gladiatorial rhetoricians, and a considerable section of his extant works are invectives. One of these, the *Dialogue against Hypocrites*, was aimed in a spirit of vindictive hatred at the vices of ecclesiastics, another, written at the request of Nicholas V, covered the anti-pope Felix with scurrilous abuse. But his most famous compositions in this kind are the personal invectives which he discharged against Filelfo and Valla. All the resources of a copious and unclean Latin vocabulary were employed to degrade the objects of his satire, and every crime of which humanity is capable was ascribed to them without discrimination. In Filelfo and Valla Poggio found his match, and Italy was amused for years with the spectacle of their indecent combats. About the year 1454 Poggio finally retired to Florence, where he was admitted to the burghership, and on the death of Carlo Aretino in 1453 was appointed chancellor and historiographer to the republic. He had already built himself a villa in Valdarno, which he adorned with a collection of antique sculpture, coins and inscriptions. In 1435 he had married a girl of 18 named Vaggia, of the famous Buondelmonte blood. His declining days were spent in the discharge of his honourable Florentine office and in the composition of his history. He died in 1459, and was buried in the church of Santa Croce. A statue by Donatello and a picture by Antonio del Pollajuolo remained to commemorate a citizen who chiefly for his services to humanistic literature deserved the notice of posterity.

Poggio's works were printed at Basle in 1538, "ex aedibus Henrici Petri." Dr Shepherd's *Life of Poggio Bracciolini* (1802) is a good authority on his biography. For his position in the history of the revival, see Voigt, *Wiederbelebung des classischen Alterthums* (3rd ed., 1893) and Symonds, *Renaissance in Italy* (1875-86). (J. A. S. X.)

POGLIZZA (Serbo-Croatian, Poljica), a tract of mountainous land in Dalmatia, Austria, formerly the seat of an independent republic. The territories of Poglizza lay chiefly within the south-easterly curve made by the river Cetina before it enters the Adriatic at Almissa (Omîš). They also comprised the fastnesses of the Mossor range (4,500 ft.) and the fertile strip of coast from Almissa to Stobrež, 10 mi W N W. The population of Poglizza numbered 6,566 in 1806. In the following year, however, the republic incurred the enmity of Napoleon by rendering aid to the Russians and Montenegrins in Dalmatia; and it was invaded by French troops, who plundered its villages, massacred its inhabitants, and finally deprived it of independence.

See the *Annuario Dalmatico* for 1885 (published at Zara); and A. Fortis, *Travels into Dalmatia* (1778).

POINCARÉ, JULES HENRI (1854-1912), French mathematician, was born at Nancy, on April 29, 1854. He studied at the École Polytechnique, devoting himself to scientific mining, and took his degree in 1879. He was lecturer at Caen and then was transferred to the University of Paris in 1881, lecturing first on physical mechanics, then on mathematical physics, and ultimately on astronomical mechanics.

Poincaré's work falls into three main divisions, his work in pure mathematics, in astronomy and in physics. Most important is his work in pure analytical mathematics, he took the main points of an existing theory, simplified it and then developed it beyond all recognition. In this way he opened up new fields for the mathematician and gave new material to the mathematical physicist. In pure analytical mathematics a good deal of his work is on the theory of functions. He developed automorphic functions and his work on the "Fuchsian" functions he applied to the non-Euclidean geometry of Lobatchevski, he also wrote a number of papers on Abelian functions. Poincaré's work on differential equations is also important, here he extended the work of Cauchy, he dealt with linear differential equations on the lines of Riemann and Fuchs and he wrote a number of papers on the differential equations which occur in physics. In astronomy he dealt chiefly with the theory of orbits, he began with an idea due to Hill and investigated the general problem of three bodies. In addition to his purely mathematical and scientific work he also wrote on philosophy. He died in Paris on July 17, 1912.

His works include *Cours de physique mathématique*, 10 vol (1889, etc.), *Leçons de la mécanique céleste* (1905, etc.), *Théorie de Maxwell et les oscillations hertziennes* (1907), *La théorie du potentiel newtonien* (1899), *Science d'hypothèse* (1903), *La valeur de la science* (1904), *Science et méthode* (1908).

POINCARÉ, RAYMOND (1860-1934), French statesman, was born at Bar-le-duc on Aug. 20, 1860, the son of Nicolas Poincaré, a distinguished civil servant and meteorologist. Educated at the university of Paris, Raymond was called to the Paris bar, and was for some time law editor of the *Voltaire*. He had served for over a year in the department of agriculture when in 1887 he was elected deputy for the Meuse. He made a great reputation in the chamber as an economist, and sat on the budget commissions of 1890-91 and 1892. He was minister of education, fine arts and religion in the first cabinet (April-Nov. 1893) of Charles Dupuy, and minister of finance in the second and third (May 1894-Jan. 1895). In the succeeding Ribot cabinet Poincaré became minister of public instruction. Although he was excluded from the Radical cabinet which followed, the revised scheme of death duties proposed by the new ministry was based upon his proposals of the previous year. He became vice-president of the Chamber in the autumn of 1895, and in spite of the bitter hostility of the Radicals retained his position in 1896-97.

In March 1906 Poincaré became minister of finance in the Sarrien Government, but he gave up his portfolio to Caillaux in October of the same year, when Sarrien was succeeded by Clemenceau as prime minister. During the next five years, though he still continued to exercise a powerful influence in the senate, Poincaré devoted himself mainly to his legal career. In 1909 he was elected a member of the French Academy. In Jan. 1912, Caillaux, who had been prime minister since the beginning of the previous year, resigned, whereupon Poincaré formed a government in which he himself held the portfolio of foreign affairs.

Poincaré's cabinet constituted an *entente nationale*, and his first aim was to pursue a more definite foreign policy. In home affairs the problem which presented the greatest difficulties was that of electoral reform. Poincaré induced the chamber to pass a proportional representation bill. But above all diplomatic affairs claimed his constant attention, for during the negotiations with Germany which took place in consequence of the dispatch of a gun-boat by that country to Agadir, certain incidents had occurred during the Caillaux administration which had produced a feeling of disquietude in regard to foreign policy. Poincaré therefore sought to re-establish a continuity of policy; and though he maintained courteous relations with Germany his main

endeavour was to prove that France would remain faithful to both friends and allies. The ratification by the senate of the Franco-German Treaty of Nov. 4, 1911, was followed by France's definite establishment in Morocco.

Almost immediately after the establishment of the Poincaré Government, an incident had occurred which temporarily obscured the friendly relations between France and Italy. The Italians, who at that moment were at war with the Turks, seized two French mail-steamer, the "Carthage" and the "Manouba," which were on their way to Tunis, on Jan. 16 and 18, 1912. But Poincaré, by his calmness and resolution, succeeded in re-establishing amicable relations between the two countries. By the end of October Italian sovereignty in Libya was recognised, and by a mutual declaration of the two Governments, full liberty of action was granted to France in Morocco and to Italy in Libya. When in the autumn of 1912 the Balkan War broke out, Poincaré made every effort possible to prevent the conflagration from spreading. Nevertheless the succession of European crises, combined with the ever-increasing menace from Germany and Austria-Hungary, rendered it necessary to take precautions, and Poincaré induced parliament to vote a programme of naval construction, through the strengthening of Franco-British relations it became possible to concentrate the whole of the French fleet in the Mediterranean.

On Jan. 17, 1913, Poincaré was elected president of the republic in place of Fallières. In power, he endeavoured to cement the friendships and strengthen the alliances of France (See FRANCE, HISTORY). At a later stage, his enemies at home and abroad criticised him severely for this policy, yet it is hardly reasonable because a man is sufficiently far-seeing to apprehend a storm and make preparations for it, to accuse him of wishing to hasten it. He claimed that he did his utmost to avert war, holding that the way to prevent the conflict was for those powers against whom the menace was directed to present a powerful and united front, thus making it imprudent to attempt any act of aggression.

In July 1914 Poincaré went to Russia on a visit which had been planned for some time past. He was on his way home, having arranged to visit the three Scandinavian capitals, when the news of the Austrian ultimatum to Serbia reached him. After a short stay in Stockholm he returned hastily to Paris, and in a letter to King George V he pleaded for a clear declaration that the *entente cordiale*, if necessary, would prove its strength on the battlefield, pointing out that such a statement would have a restraining effect on the policy of Vienna and Berlin. Throughout the World War he continued to perform his duty with the same energy and discretion as before, though sometimes he visited the front, he never placed any obstacle whatever in the way either of the Government or of the army. In Nov. 1917 he gave proof of his vision and disregard of self by placing in power Clemenceau, who, though undoubtedly the man of the moment, was one with whom he had little sympathy. During the critical months of 1918, Poincaré revealed an inflexible resolution and a supreme confidence in the ultimate victory.

During the peace negotiations divergence of views again became apparent between Poincaré and Clemenceau. On more than one occasion the president found it necessary to write to the prime minister pointing out the errors which, from his point of view, were being committed. His counsels, however, were not followed, and at the beginning of 1920, after having completed seven years as president, he left the Elysée and was shortly after re-elected senator for the department of the Meuse. In Jan. 1922, the Briand cabinet having resigned, Poincaré once more became prime minister and minister for foreign affairs. He made it his chief aim to insist on the fulfilment by Germany of her obligations in regard to reparations. During the first year of his new government he failed to arrive at any agreement on this subject with the British cabinet, whose views differed so widely from his own. The Inter-Allied Conference in London in Aug. and Dec. 1922 produced no result. A further conference took place in Paris on Jan. 2 and 5, 1923. But Poincaré rejected the proposals drawn up by Bonar Law.

At this moment, the Reparations Commission, with Britain dissenting, having declared that Germany had failed to fulfil her

obligations in regard to the delivery of coal and coke, Poincaré, in agreement with Belgium, undertook the occupation of the Ruhr (q.v.). At first this measure involved merely a method of control, but gradually, owing to the passive resistance of the Germans, it became necessary to exploit the railways and to some extent also the mines by means of Franco-British supervision. But by autumn the passive resistance had ceased, and Poincaré awaited the German proposals which never came. He then accepted the American suggestion that a group of experts should be given the task of finding the solution of the reparation problem, this resulted in the adoption of the Dawes Plan. But Poincaré had made up his mind not to withdraw from the Ruhr until he was satisfied that this plan was being carried out.

During the first three months of 1924 Poincaré had to face a financial crisis due to the state of the exchange. Not without difficulty he induced parliament to vote new taxes and succeeded in saving the situation. But from now onwards he had to withstand strenuous opposition from the parties of the Left consisting of the Radicals and Socialists. The policy of these groups met with a marked success at the general elections of May 11, 1924, and resulted in a majority for the Left which now formed a coalition under the name of the Cartel des Gauches. Immediately the results were announced, Poincaré stated that he would retire on the day when the new Chamber was to assemble, which took place on June 1, 1924.

Thenceforward he took his place in the senate, intervening only rarely in political debates. But he was to come into power once more. When, in the middle of the summer of 1926, the financial crisis, which successive cabinets since 1924 had been unable to check, became more and more serious public opinion saw in him the only man capable of meeting the situation. After the fall of the Briand-Caillaux cabinet, which only lasted a few weeks, and of the Herriot cabinet, which only existed a few hours, Poincaré, in the last days of July, formed a ministry which included both moderate Republicans and Radical-Socialists, and had as its object the stabilization of French finances by means of a policy of national union. Public opinion was immediately reassured. At the beginning of August the ministry caused the national assembly, meeting at Versailles, to pass, as articles embodied in the constitution, and therefore not at the mercy of political changes, regulations for the establishment of an automatic sinking-fund, to which would be attributed funds which could not be touched (death duties, revenues from the tobacco monopoly, etc.).

In three months he succeeded in raising the value of the franc from 264 francs to the pound sterling, to 124. This rate was achieved in Dec. 1926, and thenceforward the value of the franc did not fluctuate. For a year and a half Poincaré, who had restored a strict financial equilibrium, maintained this stabilization of the currency *de facto*. The general election of April 1928 having returned a majority which approved of his policy, a law was voted in June by the new assembly, and by the senate, establishing the stabilization *de jure*. It was one of the most successful operations of this nature in history. Withdrawal of the Radical-Socialist support from his government, engineered by Caillaux, caused his resignation on Nov. 7, 1928, but he formed a new ministry on Nov. 12. He resigned because of illness, on July 27, 1929. Poincaré undertook the publication of an important work in 10 volumes, entitled *Un service de la France; neuf années de souvenirs*, the plan of which is to describe the sequence of events from 1911 to 1920 and the rôle which he himself played in them. Four of these volumes appeared in 1926, 1927 and 1928 under the titles of *Le lendemain d'Agadir*, *Les Balkans en jeu*, *L'Europe sous les armes*, and *L'Union sacrée*. He died Oct. 15, 1934.

See H. Girard, *Raymond Poincaré* (1913); E. Charton, *L'Angleterre et M. Poincaré* (1923); S. Huddleston, *Poincaré* (1924); Sir George Arthur, ed., *Memoirs of Raymond Poincaré* (1929). (P. B.)

POINSETTIA, a popular greenhouse winter-flowering shrub of the family Euphorbiaceae. The *Euphorbia pulcherrima* of gardens, a native of Mexico and Central America, with its scarlet bracts, stands high among decorative plants. The white-bracted sort, var. *alba*, is not so effective, but the double-flowered, var. *plenissima*, in which the inflorescence is branched, is as brilliant

as the type, and keeps long in flower.

They are propagated by cuttings in spring. When taken off with a heel, cuttings strike freely in brisk heat. They require good turfy loam, with an addition of one-sixth of leaf mould and a little sand, and should be kept in a heat of from 65° to 70° at night, with a rise of 10° by day. About August they may be inured to a heat of 50° at night, and should be placed out of doors for a month under a south wall in the full sun. This treatment matures and prepares them for flowering. In autumn they must be removed to a house where the temperature is 50° at night, and by the end of September some of them may be put in the greenhouse, where they will come into flower, the remainder being placed under heat later for succession.

POINT, in finance, the unit used to estimate or quote the changes in market price of securities, commodities or exchange. In the security market a point is 1% or $\$1$ per share of stock or $\$10$ per bond. Variations in securities are quoted as low as one-hundredth of a point, $12\frac{1}{2}$ cents on stock and $\$12\frac{1}{2}$ on bonds. In commodities such as cotton, coffee and sugar the point is one one-hundredth cent per pound, and no fractional points are quoted. Thus in cotton a decline or advance of one-fourth cent a pound would be 25 points or $\$12\frac{1}{2}$ per bale. A point in exchange is one one-hundredth cent. Thus an advance in sterling from $486\frac{1}{2}$ to $486\frac{3}{4}$ would be a ten-point rise. In the English market stock is quoted at so much per £100 and the loss of a point would not necessarily mean the loss of 1% . If, for example, £100 worth of stock were quoted at "£87, dropped one point," this would be equivalent to £86. On the other hand, £100 stock quoted at "£237, gained one point" would indicate that the closing price was £238.

POINT SETS. A point set is a collection of points selected from a given space. The study of the properties of point sets constitutes that branch of mathematics known as point sets, or the theory of sets of points. Generally speaking, the properties of a point set may be classified under two heads, (1) topological and (2) metric. For a description of the former see TOPOLOGY. A brief introduction to the metric properties of point sets is given below.

The Problem of Measure.—In order to approach the subject by as simple an example as possible, let us confine ourselves to the case where the given space is an ordinary straight line, L . If P and Q are distinct points of L , then the point set consisting of P and Q together with all points between them is called an interval and is denoted by $[P, Q]$. Let us imagine that we have a common foot rule which can be applied to L in order to measure lengths. Then given an interval $[P, Q]$ we can measure its length and say that it is a certain number of feet. Of a single point we would say, in accordance with the ordinary geometry notion, that its length is zero. If we are given two intervals which have no point in common, it is not natural to speak of the length of the set of points which they represent, the word "length" being usually applied only to connected pieces. In this case we shall use the word "measure," and say that the measure of this point set is the sum of the lengths of the two intervals.

However, when we speak of a point set on L , this does not necessarily imply that we are thinking of an interval, a single point or a set of intervals, we sometimes mean to indicate a set of points which contains no connected portion, ϵ , which contains no interval. One might be tempted to say that since a point has length zero, the "measure" of such a set would be the sum of the lengths of its individual points; ϵ , the sum of a set of zeros, and hence zero. Such a hasty decision would not lead to very fruitful results, however, for the following reason. If we determine upon a "measure" for two point sets, A and B , which have no points in common, the sum of their measures should naturally be the measure of the point set which is made up by them taken together. Thus, above, we have stated that the measure of a set consisting of two intervals with no common point is the sum of the lengths of those intervals. Now any interval $[P, Q]$ can easily be shown to be the sum of two sets A and B each of which fails to contain any interval, and if we arbitrarily call the measure of both A and B zero, the sum of their measures would be zero, which is not the length of $[P, Q]$, no matter how small the length of $[P, Q]$. In

other words, we want a measure of a set of points which will correspond to the ordinary idea of length.

We have now introduced what is known, in the theory of sets of points, as the problem of measure. There have been several methods devised for finding a measure of an arbitrary set of points. We shall describe, briefly, the theory of Lebesgue measure, which is the foundation of the Lebesgue theory of integration.

Lebesgue Measure.—A set, A , is said to be covered by a collection, G , of intervals, when every point of A is in some interval of G . If the set of intervals G is denumerable, then we shall say that it is a covering of A . (A set is called denumerable if its elements can be "tagged" with positive integers in such a way that no two elements of the set are "tagged" with the same integer.) If the sum of the lengths of the intervals of G exists, let us call this the sum-length of the covering. Now of all possible coverings of A consider the corresponding sum-lengths, and let N be the largest number which is not greater than any of these sum-lengths. Then N is called the exterior measure of A and is denoted by $m_e A$. Suppose, now, that $[P, Q]$ is some interval, whose length we shall denote by d , such that all points of A are within $[P, Q]$. Let B be the set of all points of $[P, Q]$ that do not belong to A , and let $m_e B$ denote the exterior measure of B , found just as $m_e A$ was found. If it happens that $m_e A + m_e B = d$, then $m_e A$ is accepted as the measure of A , and is what is known as the Lebesgue measure of A . Of course we know at the same time that $m_e B$ is the Lebesgue measure of B , and in accordance with our ideas of length we have required that the sum of the two measures give the length of $[P, Q]$. To be sure, the Lebesgue measure of a set of points may not exist, but it does exist for all ordinary point sets. Indeed it is not at all easy to give an example of a set of points which has no Lebesgue measure, and all those examples which have been given make use of certain methods which are held to be unacceptable by many mathematicians.

For the measure of a set of points in a plane, areas are employed. Thus, the measure of the set of all points in a square is the area of the square. And to get the measure of a general plane point set M , a covering of M is made by means of squares. In three dimensions cubes are employed, and we deal with sum-volumes.

The introduction of the notion of measure has led to an enriching of the content of general analysis that could hardly have been realized otherwise. The effect has been felt not only in mathematics itself, but in the closely allied fields of mechanics and dynamics.

BIBLIOGRAPHY.—*Encyklopädie der mathematischen Wissenschaften*, Band III, Heft 7 (1924), in ss. 18–20c will be found a summary of various kinds of measure, on p. 858 are given references to applications of the notion of measure to problems in physics, astronomy, etc. E. POISON. Toxicology is the science which embodies the knowledge of the sources, characters and properties of poisons, the symptoms which they produce, the nature of their fatal effects and the remedial measures which should be employed to combat their actions or effects.

Poison is a substance which, when taken into the mouth or stomach, or when absorbed into the blood, is capable of affecting health seriously or of destroying life by its action on the tissues with which it comes into contact immediately or after absorption.

The Legal Aspect.—The law does not require that a poison should be defined further than as a substance which, when administered, is injurious to health or life. The law on the subject, as applicable to England, is contained in the Offences Against the Person act, 1861, sections II, 22, 23 and 24. With regard to poisons and abortion, sections 58 and 59 are relevant.

Section II states that whosoever shall administer, or cause to be administered to, or to be taken by, any person, any poison, or other destructive thing with intent to commit murder shall be guilty of felony. Section 22 contains the administration of substances calculated to enable the commission of a crime. It provides that any person shall be guilty of felony if unlawfully,

with intent thereby to enable himself or any other person to commit an indictable offense (or to assist any other person in committing such an offense) (a) applies or administers (or attempts to apply or administer) to any person any chloroform, laudanum or other stupefying or overpowering drug, matter or thing, or (b) causes (or attempts to cause) such drug, matter or thing to be administered to, or taken by, any person. Sections 23 likewise makes it a felony for any person unlawfully and maliciously to administer to, or cause to be administered to, or taken by, any other person, any poison or other destructive or noxious thing, so as thereby to endanger the life of such person, or so as thereby to inflict upon such person any grievous bodily harm. Section 24 enacts that if the substance was administered with intent only to injure, aggravate, or annoy, the person who administered or caused it to be administered shall be guilty of a misdemeanor. Relating to abortion, section 58 states that every woman being with child, who with intent to procure her own miscarriage, shall unlawfully administer to herself any poison, or other noxious thing, and whosoever, with intent to procure the miscarriage of any woman, whether she be, or be not with child, shall unlawfully administer to her, or cause to be taken by her, any poison or other noxious thing, shall be guilty of felony. Finally, section 59 states that whosoever shall unlawfully supply or procure any poison or other noxious thing, knowing that it is intended to be unlawfully used, with intent to procure the miscarriage of any woman, whether she be with child or not, shall be guilty of a misdemeanor.

To constitute a "noxious thing," it has been held that there must not only have been intentional administration of a noxious substance, but it must have been administered in sufficient quantity to be noxious. Within the meaning of the Offences Against the Person act, a noxious thing means a thing that will produce the effect mentioned in the statute, namely to produce miscarriage. If a substance actually produced miscarriage, that fact is sufficient to establish that it is a noxious thing. A vegetable decoction of a harmless character which as such would not produce a miscarriage is not a noxious thing. The Offences Against the Person act is applicable to England. By Scots law, to cause death by poisoning is a capital crime at common law. At common law, an attempt to poison is also a crime. Under statute, an attempt to poison is punishable by death, whether the administration of the poison was with intent to murder, to disable or to do some grievous bodily harm.

It would appear that the term "grievous bodily harm" is intended to be applied when the injury causes some measure of pain or inconvenience to the affected person, and so affects the health of that person.

The Sale of Poisons.—The following are the statutes governing the sale of poisons in Great Britain. Pharmacy and Poisons act, 1933, Poisons rules, 1935, Poisons (Colouring) rules, 1936, and statutory rules and orders made in connection with the Pharmacy and Poisons act, 1933, Dangerous Drugs act, 1951, and statutory regulations and orders made in connection with them, Therapeutic Substances act, 1925, and Therapeutic Substances regulations, 1931-44.

The objects of these acts, put broadly, are to control the sale of poisons to the public and to reduce the danger to human life from indiscriminate sale by unqualified persons. The Dangerous Drugs acts regulate the use of drugs of addiction such as opium, morphine and cocaine. With certain exceptions, only duly qualified and registered pharmacists and registered medical practitioners are permitted to sell poisons.

In the United States, the Caustic Poison act, 1927, safeguards the distribution and sale of certain dangerous caustic or corrosive acids, alkalies or other substances in interstate and foreign commerce. This act names 12 materials which are classified as dangerous: caustic or corrosive substances hydrochloric acid, sulphuric acid, nitric acid, carbolic acid, oxalic acid, salt of oxalic acid, acetic acid, hypochlorous acid, sodium hydroxide, potassium hydroxide, ammonium hydroxide and silver nitrate. The Food, Drug, and Cosmetic act, 1938, successor of the Food and Drugs act, 1906, prohibits the movement in interstate commerce of

adulterated and misbranded food, drugs, devices and cosmetics. Both the Caustic Poison act and the Food, Drug, and Cosmetic act are enforced by the food and drug administration. The U.S. public health service administers the Virus, Serum and Tissue act, 1902, which provides for the maintenance of potency and purity of biological products. The Harrison Narcotic act, 1914, and the Marihuana act, 1937, are administered by the bureau of narcotics of the U.S. treasury department. These acts regulate the importation, sale or giving away of preparations of opium or coca leaves and of marijuana, respectively.

Poisoning.—Poisoning may be accidental, suicidal or homicidal. By far the commonest type is poisoning from accidental causes. In spite of the precautions taken by the state in the sale of poisons, far too little care is taken by the public in the safeguarding of poisons in their possession. As a result, these are frequently taken by mistake instead of other substances of a harmless nature, or often an overdose is taken from pure carelessness. Thus, oxalic acid crystals when purchased in a paper packet may be transferred to an unlabelled bottle or jar and then taken by mistake for Epsom salts which they closely resemble. Similarly, tablets of corrosive sublimate have been taken by mistake instead of such harmless tablets as Blaud's pills. It is the duty of every individual possessing a substance of poisonous nature to take the utmost care that this is correctly labelled and kept safely guarded under lock and key.

Two poisons very commonly responsible for poisoning are lysol and carbon monoxide. Both are usually present in the average home.

Carbon monoxide is responsible annually for many deaths as the result of accident or suicide. It is a constituent of illuminant gas, for example, town gas, when prepared in the vertical retort, may contain as much as 22% of carbon monoxide. Defective gas heaters, especially in bathrooms, and fractured gas pipes and mains may provide a source of poisoning. Exhaust gases from internal-combustion engines also cause poisoning. It has been estimated that such gases contain from 1% to 7% depending on the richness of the mixture.

Self-administration of barbiturates is a dangerous practice, since the patient having already become confused by an initial dose of a barbiturate compound may continue, on the same occasion, to take further and possibly fatal quantities of the drug without realizing the danger. This is the possible explanation of some of the acute and even fatal cases of barbiturate poisoning which might otherwise appear inexplicable.

ACTION OF POISONS

Poisons may have a local action or a general systemic action after absorption into the circulatory system, or they may act in both ways. Almost all poisons have a general systemic action. Some poisons such as corrosives destroy the mucous membrane or tissues with which they come in contact and cause serious or dangerous injury thereby. Irritant poisons set up a local inflammatory reaction in the mucous membrane of the alimentary tract.

Apart from these local effects, the common result of absorption of a poison is the harmful effect produced on the important organs of the body, for example, the liver, kidneys, heart and nervous system are almost certain to be adversely affected. A poison after absorption attacks all the organs of the body in varying degrees, and it is a mistake to regard poisons as being exclusively selective in their action though some poisons appear to direct the brunt of their attack on a particular system.

Among the conditions affecting the action of a poison may be mentioned the following.

Amount Taken.—From the point of view of dosage, potent drugs can be divided, in an arbitrary manner, into two groups: those in which the lethal dose lies far in excess of the active dose, and those in which it lies close to the active dose. There is a definite distinction between the terms "toxic dose" and "fatal dose," since the former merely causes symptoms of poisoning while the latter induces poisoning to such a degree that death results. The term "fatal dose" when applied to a poison means

the smallest dose which is known to have caused death in an adult. Usually the quantity of a poison taken bears a relation to the effects produced. Exceptions to this rule are substances in the case of which, owing to the quantity taken, vomiting occurs so that most of the poison is expelled, oxalic acid and tartar emetic are examples. Frequently larger doses may be taken without death resulting, but much depends on other factors than quantity, and also on whether adequate treatment has been adopted.

Habit.—A tolerance to some poisons occurs after their repeated use, and in some cases doses far greater than a normal fatal dose may be tolerated without serious symptoms developing. Examples of such drugs are arsenic, morphine, opium, cocaine and alcohol. In the case of some of these poisons their repeated use leads to addiction, with all its pernicious symptoms and effects.

Idiosyncrasy.—Some persons are exceedingly intolerant of certain drugs taken in moderate doses may thus cause in them dangerous or even fatal symptoms. Examples are morphine, cocaine, quinine, iodine, bromine, salicylates and acetylsalicylic acid (aspirin), which in some persons have a severe cardiac depressant action.

Age.—Usually children are much more susceptible to the effects of a poison than adults. The dosage of drugs in the case of children has been fixed by a pharmacological rule, but exceptions to this are morphine, opium and its preparations which are much more toxic than the rule would indicate, on the other hand, children tolerate belladonna preparations better than adults. Aged persons withstand poisons badly.

State of Health.—A relatively small dose, from which a stronger person would probably recover, may kill a weakly person. In disease, drugs are usually much more toxic, and this is especially so where the excretory organs are affected. For example, in nephritis, medicinal doses of such drugs as morphine, salvarsan, hyoscine, etc., often cause dangerous symptoms, likewise in cirrhosis of the liver there is a greatly increased susceptibility to such drugs. In conditions of gastritis or enteritis, drugs like arsenic are especially toxic. On the other hand, in some conditions associated with delirium or pain, large doses of sedative drugs produce little effect provided that the excretory organs are healthy.

Condition and Mode of Administration.—If a poison is taken in solution, by the mouth, it acts much more powerfully than if taken in an insoluble form. For example, an insoluble preparation of arsenic may produce little poisonous effect even in large doses, similarly strychnine given in hard pills has a much-delayed action.

The presence of food in the stomach has a marked influence on the effect of a poison. If the stomach is empty the effect will be rapid, particularly so when the poison is in a soluble form, on the other hand, if the stomach is full, considerable delay may occur in the action of the poison as is well shown in acute arsenical poisoning.

A poison acts most rapidly when inhaled in a gaseous or vaporous form or when injected intravenously, next in order of rapidity, when injected subcutaneously; and least rapidly when ingested. Poisons may be absorbed by the skin or mucous membrane of the vagina or rectum, with fatal result.

Chemical Combination.—Some substances when in certain combinations are very poisonous, but when in others are comparatively innocuous. While the component parts of a mixture may have a poisonous action when administered singly, the compound may be comparatively inert.

Cumulative Action.—Certain poisons tend to accumulate within the body as the result of slow excretion (for example, strychnine, lead, mercury, digitalis and carbon monoxide) and therefore the continued administration of relatively small doses may occasion symptoms of poisoning.

DIAGNOSIS AND TREATMENT OF POISONING

Evidence of Poisoning.—It must be remembered that the symptoms of poisoning may be closely simulated by the symptoms of natural disease, and the greatest care must be taken before a

diagnosis of poisoning is arrived at. Thus, the symptoms of acute arsenical poisoning closely resemble those of cholera or of acute bacterial food poisoning. The only certain differentiation is the finding of arsenic in the vomit, faeces or urine, or of the bacteriological evidence of a cholera or food poisoning infection.

Various factors may provide evidence of poisoning: (1) The symptoms are usually sudden in their onset and they occur after the taking of food or drink, or after exposure to poisonous gases or vapours. (2) If several persons are similarly exposed all are affected more or less with similar symptoms. An exception may occur in the case of bacterial food poisoning, where certain persons may be relatively immune and some may be specially susceptible. (3) The analysis which should always be carried out in suspected cases may reveal the presence of the poison in the vomit, urine and faeces, and possibly also in some articles of food or medicine.

Post-mortem Evidence.—If death occurs, a post-mortem examination should be made only following instructions from the coroner. The post-mortem signs found should be consistent with those occurring from poisoning by the suspected poison. The analysis of the viscera should yield results consistent with that of poisoning by the suspected poison, taking into account the circumstances of administration and death.

Treatment.—The mode of treatment to be adopted varies according to the nature of the poison.

The poison should be removed from the stomach without delay, antidotes should be administered, the poison should be eliminated from the body by natural channels, symptomatic treatment should be undertaken and stimulation of the respiratory and circulatory systems should be resorted to immediately indications present themselves. Emetics are a poor substitute for the emptying and washing out of the stomach by means of the funnel and stomach tube, but they may be employed if the more effective treatment is impossible. Safe emetics are mustard and water, salt and water, ammonium carbonate or apomorphine. The emptying and washing out of the stomach by means of the stomach tube and funnel is, however, contraindicated when poisoning occurs from the corrosive mineral acids or alkalis. In such cases there is a danger of perforation. After the stomach has been emptied and washed out, suitable antidotes should be given, such as chalk and lime water to neutralize oxalic acid and the mineral acids, lime water for carbolic acid. Atropine may be given hypodermically in the case of morphine poisoning. Where morphia and cocaine are taken, the stomach should be washed out with diluted permanganate of potash solution.

Elimination by the bowel is facilitated by colon washes with warm normal saline solution and by free bowel evacuations. The symptoms of poisoning are subdued by the administration of appropriate remedies, thus, pain may be relieved by hypodermic injection of morphine, and the convulsions from strychnine by chloroform inhalation.

CHARACTERISTICS OF DIFFERENT POISONS

Classification.—Poisons may be classified in many different ways, e.g., according to their chemical composition, to their action on the body, to their physical characters, etc.

The following is a convenient and simple classification.

Corrosive Poisons are those which destroy by direct action the tissues with which they come in contact. To this category belong the mineral acids, such as sulphuric, hydrochloric, nitric, etc., the caustic alkalis, such as caustic soda, caustic potash, ammonia, carbolic acid, metallic poisons, such as corrosive sublimate, zinc chloride, silver nitrate. The last-mentioned will also be considered under irritant poisons. It should be remembered that corrosive poisons in diluted condition lose their corrosive effect and become irritants.

Irritant Poisons.—These poisons by their direct action on the mucous membrane set up inflammation. Examples are* oxalic acid and its soluble salts; arsenic compounds and antimony compounds, most of the metallic poisons in solution, phosphorus, bromine; iodine, boric acid, etc.

Systemic Poisons which act on the nervous system or other important organs such as the heart, liver, lungs or kidneys without

having any special irritant or corrosive effect. This group includes the majority of poisonous substances such as the vegetable poisons or their alkaloids, hydrocyanic acid and its salts, chloral, chloroform, alcohol, ether, hypnotic drugs such as veronal, sulfolal, etc. Certain poisons affect the liver and produce toxic jaundice (for example, tetrachlorethane, trinitrotoluene, picric acid, etc.), while others, such as cantharides and turpentine, involve the kidneys.

Gaseous Poisons such as chlorine, carbon monoxide and coal gas, carbon dioxide, etc. (see *War Gases*, below)

Poisonous Foods such as mushrooms, shellfish and food contaminated with dangerous pathogenic bacteria

CORROSIVE POISONS

Symptoms.—Corrosive poisons produce severe symptoms immediately they are taken—a burning pain in the mouth, throat and oesophagus and pain referred from the stomach and intestines. Vomiting occurs quickly and the vomit contains blood which may be altered in colour by the action of the poison, often also shreds of destroyed mucosa are present. Collapse occurs early, and perforation is common when, should the patient survive, signs of general peritonitis develop.

An examination of the patient will show signs of the corrosive action of the poison on the mouth and throat, and marked tenderness will be present on palpation over the stomach and intestine. Corrosive poisons if swallowed in poisonous quantity are usually fatal within 24 hours unless immediate treatment with a suitable antidote is adopted.

Should the patient survive the immediate effects of the poison, serious aftereffects result from damage to the alimentary tract, and in the case of volatile corrosives serious pulmonary complications often ensue. Post-mortem examination shows evidence of the destructive action of the poison on the mucous membrane of the mouth, throat, oesophagus and stomach, there being often extensive haemorrhage in the underlying tissues.

Among examples of corrosive poisons may be named:

The Corrosive Mineral Acids.—These include *sulphuric acid*, commonly known as oil of vitriol; it is used in various industries and in all chemical laboratories. It is a most powerful corrosive in the concentrated form, whether taken internally or applied externally as in cases of "vitriol throwing." One drachm has caused death in an adult, and half that quantity in a child.

Hydrochloric acid is known also as muriatic acid or spirits of salts. It is used largely for industrial and chemical purposes and is a common article of domestic use. It is readily obtainable and is very commonly used for suicidal purposes. It is a most dangerous corrosive and one drachm has caused death in an adult.

Nitric acid, known as aqua fortis and red spirit of nitre, is used for industrial and chemical purposes. It is a most dangerous corrosive and produces characteristic yellow staining of the tissues with which the strong acid comes in contact. The vapour of the acid, if inhaled into the lungs, often produces an acute fatal form of pneumonia which is a common cause of death in nitric acid poisoning.

Other mineral acids such as *hydrofluoric*, *phosphoric* and *sulphurous* acids in concentrated form produce similar effects.

Treatment.—The treatment of poisoning by corrosive mineral acids consists in giving as soon as possible harmless alkaline remedies such as magnesia powder, milk of magnesia, lime water or chalk. These should be administered freely, and plenty of egg albumen (white of egg) should also be given, since this tends to neutralize the acid by forming a protein combination, and also it has a soothing effect on the damaged mucosa.

The stomach should not be washed out for fear of perforation. Pain is relieved by the free use of morphine hypodermically, and after the swallowed acid has been neutralized food should be withheld by the mouth and normal saline given as freely as can be retained per rectum. In urgent cases of circulatory shock, caused by fluid loss and blood concentration, continuous intravenous infusion of normal saline, or saline with glucose, should be carried out.

The Caustic Alkalies.—Among these may be named the following: *caustic potash* or potassium hydrate or potash lye is a

powerful corrosive, and *potassium carbonate*, known as salt of tartar, has a similar but less powerful effect. Both are used industrially. Forty grains of caustic potash have caused death.

Caustic soda or sodium hydrate or soda lye is a powerful corrosive and quite as dangerous as caustic potash. It is commonly used industrially.

Ammonia, liquid ammonia or spirits of hartshorn, is used largely for domestic and industrial purposes. It is also used in the form of smelling salts when mixed with carbonate of ammonia. It is a powerful corrosive poison and in addition the vapour has a very injurious effect on the lungs, giving rise to bronchopneumonia which may assume a septic type.

As regards treatment following ingestion, harmless acid drinks such as diluted vinegar, lemon juice, citric or tartaric acid should be given freely. Olive oil or egg albumen may be usefully employed. Pain should be relieved by the free use of morphine hypodermically and nourishment should not be given by the mouth, but rectal feeding adopted.

Corrosive Organic Acids.—*Carbolic acid*, or phenol, is commonly used as a disinfectant for domestic and surgical purposes. Allied preparations such as creosote or cresol have a similar poisonous effect. Lysol is a combination of cresol with soap and is similar in action to phenol.

Carbolic acid and the allied substances have a powerful corrosive action causing necrosis of the tissues with which they come in contact, the superficial part of which becomes of whitish appearance, the deeper parts becoming dark red as a result of haemorrhage into them. Carbolic acid is one of the poisons most frequently used by suicides, and owing to its common use for domestic purposes is also a frequent cause of accidental poisoning.

The symptoms caused by carbolic acid are those of corrosive poisoning, but owing to its local anaesthetic action vomiting may be absent and pain may be less marked. If death does not result from shock, the profound effect of the poison on the nervous system causes paralysis of the respiratory and cardiac centres, with rapid feeble pulse and stertorous breathing, coma develops in severe cases and is usually followed by death. Death has also resulted from absorption by the skin, and from rectal injections in solution. Usually death occurs within three to four hours following ingestion of a large dose.

The aim of treatment is to limit the absorption of the poison, to sustain the patient and to aid the elimination of the poison from the system. The stomach should be washed out by means of a soft stomach tube with diluted saccharated lime water or fresh lime water, by this means the phenol is converted into calcium phenate which is not poisonous. Alternatively, thorough gastric lavage, using a 10% solution of glycerine, or plain water, should be carried out without delay until the washings no longer emit an odour, and a quantity of medicinal paraffin should be left in the stomach. Egg albumen, since it precipitates phenol, will delay absorption. When necessary, rectal feeding should be adopted for several days.

IRRITANT POISONS

The more important irritant poisons will be considered under this heading (*vide list above*), but it must be remembered that many of the general poisons (*e.g.*, savin, cantharides, etc.) have an irritant action on the stomach and intestines in addition to their special action on important organs and nerve centres.

Oxalic acid occurs in colourless crystals resembling Epsom salts, it is very soluble in water. *Salts of sorrel* or *salts of lemon* is the quadroxalate of potash, it is a white powder very soluble in water. Both of these substances are commonly used for domestic purposes, *e.g.*, for cleaning straw hats, removing ink stains, cleaning brasses, etc. They are frequently the cause of accidental and of suicidal poisoning.

When swallowed in solution the typical symptoms of irritant poisoning are set up, but in addition the poison when absorbed into the system has a profound depressant action on the heart and nervous system. Thus an acrid burning taste is experienced and pain occurs which is referred from the throat, oesophagus and

stomach and later possibly from the intestines. Vomiting is common, the vomit being very acid, and giving positive results to the tests for oxalic acid. It often contains blood. Unless immediate treatment is adopted collapse speedily occurs, the patient becoming cold, pale and faint with a rapid feeble pulse, at this stage death from syncope may occur. In some cases nervous symptoms such as unglings and numbness, muscular spasms, convulsions, delirium and coma occur, but these symptoms are uncommon. Owing to the rapid absorption of the poison death is likely to occur rapidly (e.g. within an hour), but it may be delayed.

For treatment, fresh lime water or, preferably, saccharated lime water which is 15 times as strong, should be given in large quantities and it should be mixed with calcium carbonate in the form of chalk or whiting. Since oxalic acid has only slight corrosive action the stomach should be washed out immediately if no antidote is at hand. It is best to give the antidote freely if immediately available and after a few minutes to wash out the stomach thoroughly with a soft stomach tube and funnel, and then finally introduce a pint of lime water made into a thin cream with an ounce of chalk, leaving this mixture in the stomach. Intravenous injections of calcium chloride or gluconate (calcium Sandoz) are recommended.

Arsenic is the most important of the irritant poisons and owing to the tasteless property of many of its compounds and preparations it is the commonest poison used for homicidal purposes.

The most notable and commonest compound is arsenious acid, arsenous oxide or white arsenic. It exists in the form of a white powder or in lumps of a white porcelainlike appearance. The powdered form resembles powdered sugar or flour and when mixed with food is almost tasteless. It is sparingly soluble in cold water, which will dissolve only 0.03 to 0.06 g. in 30 ml. About 4 g. in 30 ml., however, will be held in boiling water. When mixed with alkaline substances, white arsenic becomes freely soluble.

Commercial preparations containing white arsenic mixed with alkalis such as sodium hydrate or carbonate are weed killers, sheep-dip and wood preservatives which may contain from 20% to 40% of white arsenic. Copper arsenite (Scheele's green), lead arsenate and other arsenical preparations are used as insecticides for the spraying of fruit trees. Rat poisons may contain arsenic as the active ingredient. Wallpapers which formerly often contained green pigment (Scheele's green) or the yellow sulphides of arsenic are now coloured with arsenic-free pigments, arsenic being prohibited from use. White arsenic, if sold for other than medicinal purposes, must be mixed with a dye of distinctive colour which is water soluble.

Accidental contamination of food with arsenic has occurred in the past. Thus in 1900 a beer poisoning epidemic occurred as the result of the use of commercial glucose which contained arsenic in the preparation of beer. Prosecutions have been brought for the presence on apples of prohibitive amounts of arsenic alleged to have been caused by spraying of trees (*See ADULTERATION*).

When arsenic is taken by the mouth in poisonous quantities, symptoms of acute gastrointestinal irritation such as vomiting, diarrhoea and abdominal pain usually occur within a few hours. Death may ensue within a period varying from several hours to several days. A dose of 0.12 g. of arsenic has caused death, though larger quantities have been taken without fatal result. In acute arsenical poisoning the heart, kidneys and other organs are seriously affected so that the poison has a systemic action in addition to its irritant properties to the stomach and intestines.

Chronic arsenical poisoning occurs when small quantities of arsenic are absorbed over long periods. The gastrointestinal symptoms may be slight, but other symptoms, such as gradual loss of weight, alopecia, skin rashes and pigmentation and conjunctivitis, become manifest.

In suspected acute arsenical poisoning the diagnosis can be made certain by analysis of the vomit, urine and faeces. In chronic cases additional information may be obtained by analysis of the hair and nails.

Antimony is an irritant poison like arsenic. Tartar emetic or potassium antimony tartrate is one of the most commonly used

compounds. It has on several occasions been used for homicidal purposes owing to the possibility of its being administered without detection by taste or smell.

Metallic poisons if taken by the mouth give rise to irritant poisoning. Examples are:

In large doses, the common salts of lead will cause gastrointestinal irritation. Acute poisoning by lead is rare. Chronic lead poisoning is caused by continued absorption of small quantities of lead and is a dangerous condition as it causes disease of the kidneys, blood vessels, heart and nervous system. Lead tetraethyl is a very poisonous organic compound of lead. It is used commercially as a constituent of ethyl gasoline, and is claimed to counteract "knocking" or "pinging" in motor engines. On inhalation in sufficient quantity it is extremely toxic. The sulphate of copper (blue vitriol) and other copper compounds are irritant poisons. The use of copper salts as a colouring matter of foodstuffs such as preserved green vegetables is reprehensible, and has often led to legal action. The Public Health (Preservatives, etc. in Food) regulations of England, 1925-40, prohibited all save scheduled colours and limited the preservatives to benzoic and sulphurous acids and sodium or potassium nitrate, and these only in specified amounts in certain foods.

Zinc salts are irritant poisons. The sulphate of zinc (white vitriol) occurs in crystals like Epsom salts for which it has been taken in mistake. Zinc chloride has a corrosive as well as an irritant action.

Barium salts, except for the quite insoluble sulphate, are irritant poisons and may also act on the cardiovascular or nervous system.

Chromates especially potassium bichromate are powerful irritant poisons.

The yellow variety of phosphorus is intensely poisonous and formerly was widely used in the manufacture of matches. Yellow phosphorus is used as a constituent of some vermin exterminators. The substance, in addition to being a gastrointestinal irritant, is a deadly poison to the liver and kidneys.

Acute mercurial poisoning usually arises from the taking of mercuric chloride (corrosive sublimate) or from the bismode of mercury, both of which are extensively used as disinfectants for medical purposes. The immediate symptoms are those of acute gastrointestinal irritation (vomiting, abdominal pain and diarrhoea) but they are generally followed by suppression of urine and symptoms of acute ulcerative colitis which latter symptoms are commonly fatal. Chronic mercurial poisoning is characterized by inflammation of the mouth and gums.

SYSTEMIC POISONS

The systemic poisons include the following:

Prussic or Hydrocyanic Acid—Hydrocyanic acid is one of the best known poisons and a very deadly one. In the pure state it is said to kill with lightninglike rapidity. It is met with in commerce only in a dilute state. In Great Britain two kinds of acid are commonly sold—the pharmacopoeial acid, containing 2% of anhydrous prussic acid, and Scheele's acid, containing 4% to 5%. About four millilitres of the 2% acid may cause death.

Hydrocyanic acid and the cyanides must be regarded as true protoplasmic poisons since they arrest the activity of all forms of living matter by inhibiting tissue oxidation and suspending vital functions. Such poisons not only inhibit the enzymic activities, but also act upon the central nervous system.

Given in fatal doses, the symptoms of prussic acid poisoning set in with great rapidity, and, in consequence of the readiness with which the poison is absorbed from the stomach and diffused through the circulation, the onset of symptoms is reckoned by seconds rather than by minutes. Occasionally the victim may be able to perform a few voluntary actions before loss of consciousness. There is first a very brief stage of difficult breathing and slow action of the heart, with a tendency for the organ to stop in the state of dilatation. With widely dilated pupils of the eye, the patient is then seized with violent irregular convulsive movements. The rhythm of the respiratory movements is disturbed, and the countenance assumes a bluish colour. The patient collapses with complete loss of muscular power, and the third or

apneustic stageris reached, in which there are slow gasping respirations, loss of pulse and paralysis of motion. Death is frequently preceded by spasms. The lightninglike character of the illness and the speedy death of the patient, coupled with the peculiar odour of the acid in the breath and atmosphere around the body, seldom leave any doubt as to the nature of the case.

Other soluble cyanides, more especially cyanide of potassium, a salt largely used in photography and in the arts, are highly poisonous but are slightly less rapid in action than hydrocyanic acid.

When the poison has been swallowed, the stomach should be washed out immediately and free lavage established. A suitable medium for the purpose is water at body temperature containing a 5% to 10% solution of sodium thiosulphate, or a mixture of the sulphates (ferrous and ferric) of iron followed by a solution of potassium carbonate to form Prussian blue which is inert. Sodium thiosulphate (10 to 50 ml of 20% solution) or methylene blue (50 ml of 1% solution) may be administered intravenously, provided there is time for either of these preparations to act. Ammonia inhalations, artificial respiration and oxygen, with or without carbon dioxide (7%), should be used to stimulate respiration. In desperate cases, a slow venous injection of five millilitres of a 25% solution of coramine has been recommended. Stimulation of the cardiac and respiratory centres may be effected by injections of lobeline and cardiazol.

Strychnine and Strychnine-Yielding Plants.—The alkaloids strychnine and brucine, as well as the plants in which they are found, all act in the same manner, being highly poisonous and causing death after spasms of a severe character. Many vermin killers contain strychnine as their active ingredient.

Strychnine and all substances containing that alkaloid usually produce their effects within 10 or 15 min. The patient complains of stiffness about the neck, and his aspect exhibits terror. There is an impression of impending calamity or death. Very speedily the head is jerked back, the limbs extended, the back arched (opisthotonos) so that the body may rest on the head and heels only. In a few moments these symptoms pass off, and there is complete relaxation of the spasm. The spasmodic condition speedily returns, and is brought about by the slightest touch or movement of the patient. Accessions and remissions of the tetanic state ensue rapidly till the patient succumbs, usually within half an hour of the administration of the poison.

The best treatment is to put the patient under the influence of chloroform and wash out the stomach with a solution of potassium permanganate in water, four grams in two gallons. To follow, medicinal charcoal in water is recommended, and this should be freely given and removed from time to time. Sodium amylal or phenobarbital sodium should be given intravenously. Only a sufficient quantity to put the patient to sleep should be given, or, if convulsions are present, only enough to stop them.

Nicotine.—The alkaloid nicotine is obtained from the plant *Nicotiana tabacum* and has a pungent, acrid taste. Its content in tobacco leaves varies from 0.6% to 6%. Poisoning may be caused by absorption through the skin, by inhalation or by ingestion. Industrial poisoning caused by commercial preparations, such as fertilizers and fumigants, has occurred.

Cases of acute poisoning are comparatively rare, but subacute and chronic symptoms may result from the immoderate use of tobacco. When nicotine is absorbed in poisonous dose, the outstanding symptoms are those of successive central and peripheral stimulation, nausea, sickness, tachycardia, cardiac oppression and irregularity and severe prostration and cardiovascular collapse may become manifest. Treatment consists of gastric lavage when the poison has been ingested. Strong coffee or a hypodermic injection of coramine should be given.

Opium.—In consequence of the extent to which opium, its preparations and its active alkaloid morphia are used for the relief of pain, poisoning by opium is of frequent occurrence. It is largely used by suicides, and children, being very susceptible to its influence, frequently die from misadventure after administration of an overdose of the drug. The ordinary preparations of opium are the drug itself, which is the inspissated juice of the

oriental poppy, and the tincture, commonly known as laudanum. Opium contains a variety of more or less active principles, the chief of which is the alkaloid morphia, which is present in good opium to the extent of about 10% in combination with meconic acid, which is physiologically inactive.

The treatment of opium poisoning is governed by the condition of each case in relation to the time of intake. It consists of free gastric lavage with warm water and then with two grams of potassium permanganate in two gallons of warm water. The use of medicinal charcoal is beneficial. In coma, the airway should be kept clear, the patient catheterized and artificial respiration and inhalations of oxygen, or of oxygen with 7% carbon dioxide, should be employed if thought necessary.

Heron.—This is an artificial derivative of morphia (diacetyl morphia hydrochloride) and is more toxic than morphia. It has been largely used medicinally. It is a dangerous drug of addiction.

Belladonna.—The belladonna, or deadly nightshade, *Atropa belladonna*, contains an alkaloid, atropine, which is largely used by oculists to procure dilatation of the pupils of the eye. The brown or black berries of the plant have been eaten by children, who are attracted by their appearance. Besides dilatation of the pupils, belladonna produces rapid pulse, hot, dry, flushed skin with an eruption not unlike that of scarlatina, soreness of the throat with difficulty in swallowing, and intense thirst and delirium.

The treatment consists of gastric lavage with a solution of 1 in 5,000 of potassium permanganate. Excitement should be controlled by sedatives or mild hypnotics. Lumbar puncture may prove beneficial in certain cases.

Stramonium, hyoscyamus (henbane), hyoscyamine, hyosine and scopolamine all produce symptoms similar to atropine poisoning, the narcotic effects being more marked.

Aconite.—The ordinary aconite, wolfsbane or monkshood (*Aconitum napellus*), and an alkaloid extracted from it, aconitine, are perhaps the most deadly of known poisons. A dose of 0.004 g of aconitine has proved fatal to man. The root of aconite has been eaten in mistake for that of horse-radish. All the preparations of aconite produce a peculiar burning, tingling and numbness of the parts to which they are applied. When given in large doses they produce violent vomiting, as a rule, more or less paralysis of motion and sensation and great depression of the heart, usually ending in death from syncope. Intelligence remains unaffected till almost the last.

The treatment consists of free gastric lavage with a solution composed of 12 g of tannic acid in two gallons of warm water. Tannic acid (12 g in 180 ml of tepid water) should be given and followed by animal charcoal suspended in water. Cardiac and respiratory stimulants should be administered in accordance with clinical indications. Artificial respiration and oxygen inhalations may prove necessary.

Cocaine.—Cocaine is the active alkaloid of coca leaves—*Erythroxylon coca*—and is chemically methyl benzoylecgonine. The hydrochloric salt is the commonly used preparation. It is a powerful deliriant narcotic poison. If taken by the mouth, given hypodermically or otherwise absorbed, it may cause delirium and coma. Sometimes convulsions and sudden death occur. It acts on the heart and may cause fatal syncope. Cocaine is a dangerous drug of addiction (see DRUG ADDICTION).

Organic Compounds Used as Hypnotics.—These if taken in excessive doses act as poisons, and the symptom which attracts attention is the deep coma produced.

Examples are, chloral, veronal and its derivatives, medonal, propional, luminal, sulfonal, trional and tetralol. Any hypnotic drug taken in excessive quantity will act as a coma-producing poison. (See BARBITURIC ACID, SULFONAL GROUP, THE.)

GASEOUS POISONS

Gaseous poisons include the following.

Carbon Monoxide.—Poisoning by carbon monoxide may occur from coal gas, water gas or from exposure to the suffocating fumes of fires, smoky gases and stoves, also from the fumes of gas heaters and internal-combustion engines.

The diagnosis may be made at once from the clinical symptoms of drowsiness, collapse and coma, and the cherry-red colour of the face, body and mucous membranes. Examination of the blood will make the diagnosis certain, since the presence of carboxyhaemoglobin may be readily detected by the spectroscope.

The treatment consists in giving oxygen with 7% carbon dioxide freely, and employing artificial respiration if necessary. The use of carbon dioxide is important since it stimulates breathing and breaks down the carbon monoxide-haemoglobin molecule. The body warmth must be maintained. This is important since carbon monoxide disturbs the heat-regulating centre with reduction in the processes of oxidation. Stimulants administered hypodermically will also prove beneficial.

Carbon Dioxide or Carbolic Acid—This occurs in coal mines from chokedamp or afterdamp. Cells of houses, wells, brewers' vats, lime kilns, etc., frequently contain large quantities of carbolic acid gas.

The treatment consists in fresh air, rest, oxygen, artificial respiration if necessary, and employment of warmth and stimulants.

Sulphuretted Hydrogen—This occurs from contamination of the air with sewer gas, and from the gases evolved when iron slag becomes moistened with water. The gas is frequently produced in various chemical processes.

The treatment consists in giving the patient plenty of fresh air. Oxygen and stimulant treatment must be used.

WAR GASES

Despite the fact that a mixture of gases may be employed, it is customary to classify war gases into four groups: (1) gases producing irritation of the lungs (choking gases), (2) gases producing irritation of the nose (nasal irritants), (3) gases producing irritation of the eyes (lachrymators), and (4) gases producing irritation of the skin (vesicants).

Group 1 includes phosgene, diposgene, chlorine and chloropierin. All these gases when inhaled produce rapid bronchial and pulmonary irritation which may lead to death within a day or two from cardiac failure brought about by inflammatory oedema. A later fatal complication results from bronchopneumonia.

Group 2 includes smokes which are liberated from the highly toxic arsenical compounds diphenylamine chlorarsine, or DM, diphenyl chlorarsine, or DA, and diphenyl cyanarsine, or DC. These are capable of causing profound sensory disturbance which in warfare diminishes physical capacity and undermines morale.

Group 3 includes ethyl iodacetate, or KSK, bromobenzyl cyanide, or BBC, and chloroacetophenone, or CAP. The vapours of these substances produce transient irritating effects on the eyes, which water copiously. If the liquids from which these vapours arise are brought into contact with the eyes severe and permanent damage may result.

Group 4 includes bis β -chloroethylsulphide, or mustard gas, and β -chlorovinylidichlorarsine, or lewisite. These liquids give off toxic vapours which affect the lung, eye and skin on account of their irritant action. In their liquid form such fluids cause severe burning with destruction of the tissue with which they are brought into contact. Their power of penetration of the skin is very considerable since they are capable of producing lipid solubility. Mustard gas has a delayed action and on this account serious delay in treatment may occur. Lewisite acts much more rapidly. The arsenic content of lewisite when absorbed by the skin may produce tissue damage in the secretory and urinary systems. (See CHEMICAL WARFARE.)

FOOD POISONING

Food poisoning may be defined as poisoning induced by the ingestion of food-containing toxic principles, metallic or otherwise, or pathogenic organisms. Thus poisoning may arise from vegetable poisons, including fungi, animal poisons, including shellfish; chemical poisons, and bacterial food poisons, including botulism. It must not be forgotten, however, that sensitivity to certain food items may exist in a given individual and may give rise to manifestation of illness, such as signs and symptoms of gastrointestinal disorder, or to a skin lesion urticarial in character.

So-called mushroom poisoning is usually caused by the ingestion of toxic fungi instead of edible mushrooms. Such fungi frequently belong to the genus *Amanita*, especially the species *phalloides* and *muscaria*. Poisoning by the edible mussel, *Mytilus edulis*, is not uncommon, and the illness usually assumes a mild form, with urticarial manifestations, occasionally accompanied by asthma. Little need be said of chemical poisons which may contaminate food, since many of these have already been described.

True bacterial food poisoning, frequently, although not invariably, associated with canned food, was formerly termed ptomaine poisoning, but after the discovery that ptomaines, chemical substances related to amines, are harmless when administered by the mouth, this misleading term fell into disuse. Bacterial food poisoning is principally caused by various strains of the *Salmonella* group, and the commonest are perhaps *S. aertrycke* and *S. enteritidis* of A. Gartner, the latter occurring in outbreaks. In 1945 at Stoke-on-Trent, Eng., about 30 cases of food poisoning occurred. There were six deaths, and the cause of all the deaths was *S. enteritidis*. *Clostridium botulinum*, a sporing anaerobe, whose normal habitat is garden soil, produces a fatal type of food poisoning. The exotoxin which this organism secretes is one of the most powerful yet discovered. The condition of poisoning which is produced is known as botulism or allantois. Its manifestations consist of paralysis of the muscles of the eyes and eyelids, the larynx and finally of the respiratory centre. The outbreak in Europe are most frequently caused by meat or meat foods, while those in the U.S. have generally been traced to vegetable products. An outstanding British outbreak occurred in Scotland at Loch Maree in 1922, when all of eight persons who ate sandwiches filled with potted duck paste died. The incubation period is usually less than 48 hr. and may be as short as 4 hr.

POISON FISH (*Synanceia verrucosa*), an ugly, rather shapeless, tropical, marine-bottom fish, of the family Scorpaenidae, reaching a length of about one foot, inconspicuous as it lies partly buried in the sand or in some hollow of a rock or coral bottom, which it commonly does.

Though veiled in skin, the spines of the dorsal fin of the poison fish have large poison glands at their bases and can inflict a severe wound. Like the related lion fish (*P. v.*) this species is found in the Indian ocean, East Indies and eastward into Polynesia (see SCORPEN FISHES).

(J. T. N.)

POISON GAS: see CHEMICAL WARFARE.

POISON HEMLOCK: see WATER HEMLOCK.

POISON IVY, the name commonly applied to several, mostly white-fruited, trifoliate species of woody vines or shrubs of the genus *Toxicodendron* (family Anacardiaceae), native to North America. The forms with bushy habit and lobed leaflets are often called "poison oak," especially in the western United States. The common poison ivy (*Toxicodendron radicans*), the most widespread species, abundant in eastern North America and less common westward, is a variable species with a bushy or climbing habit, leaves with three leaflets which may be smooth and glossy or hairy, entire, toothed or lobed. Many of these not too constant variations have been designated as separate species or varieties.

The more common of these forms with their ranges are *T. quercifolium*, with deeply lobed leaflets, Maryland to Texas, *T. radicans* *rydbergii*, with thicker leaves, Great Plains to Rocky mountains, and *T. diversilobum*, with leaflets mostly scalloped on the margin, Pacific coast. The poison sumac (*T. vernix*), native in swamps from Quebec to Minnesota and south to Texas and Florida, is a tall bush or small tree with pinnately compound leaves with 7 to 13 entire leaflets and drooping, axillary clusters of persisting white fruits. All species of *Toxicodendron* are poisonous to touch, producing in many persons a severe inflammation of the skin or dermatitis. Sumacs with red fruits are nonpoisonous. The toxic principle, urushiol, is produced in the resinous juice of the resin ducts of the leaves, flowers, fruits and bark of stems and roots but not in the pollen grains. Being almost nonvolatile, the urushiol may be carried from the plant on clothing, shoes, tools, soil, by animals, by smoke from burning plants, to persons who never go near the poison ivy plants. Poisoning may occur if clothing is worn a year after contact with poison ivy.

The remedies and preventive treatments used against poisoning from contact with species of *Toxicodendron* are legion. With the exception of the following, none should be used without the advice of a physician. Either before exposure, or immediately after it is discovered that contact has been made with the plant, wash the exposed parts of the body thoroughly with water and an alkaline laundry soap. Lather the parts well and let the lather dry on. Repeat this treatment every three or four hours, leaving the dry lather on between applications. Avoid only soaps or washing with alcohol to prevent spreading the toxic material.

(W. C. M.)

POISONOUS PLANTS.

It is not practicable to divide the members of the vegetable kingdom into poisonous and nonpoisonous plants. Most of the 250,000 known species of plants are harmless, only a relatively few are poisonous under ordinary conditions, others are poisonous only under special conditions. Poisonous plants under natural conditions contain or produce physiologically active substances in quantities sufficient to cause death or a disease condition when eaten, or sometimes when touched, by man or animals.

In general the toxic properties of poisonous plants result from the presence, in some or all parts of the plant, of one or more organic compounds such as alkaloids, glucosides, resins and organic acids. Alkaloids are responsible for the toxic properties in certain members of the families Liliaceae, Amaryllidaceae, Papaveraceae, Ranunculaceae, Leguminosae and Solanaceae. Among the glucosides that yield toxic substances upon hydrolysis are those produced in wild cherries (*Prunus* spp.), flax (*Linum* spp.), corn cockle (*Agrostemma githago*), foxglove (*Digitalis purpurea*) and various members of the mustard family, Cruciferae. Resinoids containing toxic substances occur in poisonous members of the heath family Ericaceae, water hellebore (*Cicuta maculata*) and milkweeds (*Asclepias* spp.).

Not all parts of a poisonous plant are equally toxic. In some the toxic principle is mostly concentrated in the seed (e.g., corn cockle (*Agrostemma githago*)), in others the root is the most toxic part (e.g., water hellebore, *Cicuta maculata*). Some plants are toxic only in certain stages of development. The cocklebur (*Xanthoxylum orientale*) is very poisonous in the seedling stage and harmless in later stages of growth. Other plants are poisonous when eaten green but are harmless after they are thoroughly dried and the toxic principle is dissipated.

Some plants (e.g., certain locoweeds, *Astragalus* spp.) vary greatly in their toxicity, depending upon the type of soil on which they grow.

Most cases of poisoning from eating toxic plants occur in animals, comparatively few occur in man. Some plants, such as water hellebore (*Cicuta maculata*), poison hemlock (*Conium maculatum*) and locoweeds (*Astragalus* spp.), produce characteristic symptoms in animals poisoned by eating them. Many poisonous plants, although belonging to widely unrelated plant families, may produce identical symptoms because their toxic principle is the same, e.g., species of wild cherries (*Prunus* spp.), sorghum (*Holcus* spp.) and arrowgrass (*Triglochin maritima*) all produce the same symptoms because the toxic principle in them is prussic acid, which under certain conditions is released by the hydrolysis of glucosides produced in them. Another example of a disease caused by widely different plants is trembles, caused by white snakeroot (*Eupatorium rugosum*) in the eastern United States and by the rayless goldenrod (*Aplopappus heterophyllus*) from western Texas to Arizona and adjacent Mexico. In these plants the toxic principle is tremetol, which, being soluble in the fat of milk, may be transmitted from diseased cows through the milk to humans, causing the disease known as milk sickness. Some plants (e.g., scouring rushes [*Equisetum* spp.] and locoweeds [*Astragalus* spp.]) may produce different types of diseases, acute or chronic, depending upon whether an animal eats a large quantity of the plants at one time or small quantities repeatedly for a considerable time.

Among cultivated plants the following poisonous species, originating mostly in the old world, are common and widely grown in the temperate regions: castor bean (*Ricinus communis*), daphne (*Daphne mezereum*), foxglove (*Digitalis purpurea*), lily-of-the-valley (*Convallaria majalis*), meadow saffron (*Colchicum autumnale*), monkshood (*Aconitum napellus*), larkspur (*Delphinium* spp.), narcissus (*Narcissus poeticus*), oleander (*Nerium oleander*).

Plants Poisonous by Contact.—Most cases of contact poisoning by plants occur in man, animals are rarely poisoned by contact alone. In man certain plants produce a skin poisoning or dermatitis consisting of minor or temporary irritation or a painful inflammation with vesicles or blisters lasting for days or weeks, depending upon the susceptibility of the individual or the severity of the infection. The toxic principle in these plants is often most concentrated in a resinous or milky juice. Among the species which cause many cases of dermatitis may be mentioned the following:

Cashew Family.—Poison ivy and poison oak (*Toxicodendron radicans*) and related forms, common in North America, poison sumac (*Toxicodendron vernix*), eastern North America, poison wood (*Meltopium tozerianum*), of southeastern United States and West Indies, Japanese lacquer tree (*Toxicodendron vernicifluum*), eastern Asia, cashew (*Anacardium occidentale*), widespread in tropical regions.

Spurge Family.—Manchineel tree (*Hippomane mancinella*), common in the West Indies and Central America, sandbox tree (*Hura crepitans*), native to Central American lowlands, spurges (*Euphorbia* spp.), many species, especially some native to Africa and Asia, very toxic, snow-on-the-mountain (*Euphorbia marginata*), an annual native to western North America, widely introduced as an ornamental. A few species of primrose, notably *Primula obconica*, a favourite house plant, several kinds of lady-slipper (*Cypripedium reginae* and *C. parviflorum*), native to eastern North America, the garden pansy (*Pastinaca sativa*), often escaped as a weed, and several species of milkweed (*Asclepias*)

are responsible for dermatitis in many susceptible persons

Photodynamic Plants—Several plants appear to contain substances that sensitize domestic animals to light. If animals with white fur or unpigmented skin eat these plants and are subsequently exposed to strong sunlight they may develop a disease with characteristic symptoms that may result in death. Animals that are not exposed to sunlight subsequent to eating these plants do not develop any symptoms. Some of the widely distributed photosensitizing plants are buckwheat (*Fagopyrum esculentum*), St. Johnswort (*Hypericum perforatum* and *H. crispum*), but clover (*Medicago denticulata*) and puncture vine (*Tribulus terrestris*).

Seleniferous Plants—Several species of plants when growing on certain soils from Cretaceous or Eocene shales take up enough selenium compounds to make them toxic. In several regions in western North America, cattle and horses have been poisoned by eating such seleniferous plants, resulting in alkali disease and blind staggers. Selenium absorbed from seleniferous shales by these plants upon their decomposition is returned to the soil and becomes available and may be taken up by other native plants or by crop plants that are unable to absorb inorganic selenium. By such action crops such as wheat may become poisonous. The locoweeds (*Astragalus bisulcatus*, *A. pectinatus*, *A. racemosus*), wild aster (*Aster commutatus* and *A. zylorhiza*) and prince's plume (*Stanleya bipinnata* and *S. pinnata*) are examples of seleniferous plants of western North America.

Principal Stock-Poisoning Plants—Several forms of bracken or brake-fern (*Pteridium*) occurring in widely distributed places throughout temperate regions from Eurasia to Australia and North America, when eaten fresh or in hay over a prolonged period, are the cause of poisoning of cattle and horses. Horsetail (*Equisetum arvense*) of Eurasia and North America causes an acute or chronic disease, equisetosis. Arrowgrass (*Triglochin maritima*) of Eurasia, North Africa and North America produces prussic acid which poisons cattle and sheep. Darnel (*Lolium temulentum*), native to Europe and introduced in North America, contains a poison in its grains. Death camas (*Zygadenus venenosus*) and related species, all native to North America, contain toxic alkaloids and cause considerable losses among sheep and cattle grazing on ranges in the spring. False hellebore (*Veratrum viride*), widespread in North America, and the European *V. album* contain toxic alkaloids.

Fly poison (*Amanthium muscaetoxicum*) causes losses among cattle and sheep in the eastern United States. Lily-of-the-valley (*Convallaria majalis*), native to Europe and the eastern United States, widely cultivated as an ornamental, contains toxic alkaloids. Star-of-Bethlehem (*Ornithogalum umbellatum*), native to Europe and naturalized in North America, and other species of *Ornithogalum* native to South Africa cause poisoning of cattle and sheep. Meadow saffron (*Colchicum autumnale*), native to Europe and widely introduced in North America, contains toxic alkaloids. Lechuguilla (*Agave lecheguilla*), native to southwestern United States and Mexico, contains a photosensitizing agent and causes poisoning, chiefly of sheep and goats.

Pokeweed (*Phytolacca americana*), native to eastern North America, contains a toxic alkaloid chiefly in the root. Corn cockle (*Agrostemma githago*), native of Eurasia and widely naturalized in most regions where winter wheat is grown, contains a toxic glucoside in its seeds. Monkshood (*Aconitum napellus*), a native of Europe, and *A. columbianum*, native of the mountain

ranges of western North America, both contain toxic alkaloids. Larkspurs (*Delphinium* spp.) contain toxic alkaloids, several species native to western North America cause heavy losses when grazed by cattle. Hellebore (*Helleborus niger* and *H. viridis*), native to Europe and introduced in North America, contain toxic glucosides. Opium poppy (*Papaver Somniferum*), of Asiatic origin and widely introduced in warmer parts of the world, contains several alkaloids. Dutchman's breeches (*Dicentra cucullaria*) and squirrel corn (*D. canadensis*), native to eastern North America, contain toxic alkaloids and cause blind staggers in cattle and sheep. Wild cherry (*Prunus serotina*), a common native tree in the eastern North America, produces a toxic principle in western North America, the cherry laurel (*P. laurocerasus*) of Europe and other species contain a glucoside that may yield prussic acid upon hydrolysis. When the leaves of these plants are eaten by cattle or sheep, death may result quickly.

Several European and North American species of lupines (*Lupinus* sp.) contain toxic alkaloids. In western North America losses among cattle and sheep grazing on lupine seed pods may be large. A number of species of locoweeds (*Astragalus* sp. and *Oxytropis* sp.) native to North America in the region from the Great Plains westward to the Rocky mountains are poisonous and when eaten cause loco disease in cattle and horses. The plants appear to be habit forming, and animals may develop a habit of seeking out locoweeds in preference to other vegetation. The disease may be acute from eating large amounts at one time, or chronic from eating small amounts over a long period. Some, but not all, locoweeds owe their toxic properties to selenium compounds absorbed from the soil.

Precatory bean (*Abrus precatorius*), a native shrub of India, is widely introduced in subtropical regions.

Its seeds contain a toxic substance, abrin, and may poison cattle and sheep. In India immunity has been developed in animals by feeding them very small amounts of the abrin and gradually increasing the dose. Black locust (*Robinia pseudoacacia*), a native tree of eastern North America and widely introduced in Europe, contains a toxic substance in its bark. Horses are sometimes fatally poisoned by eating the bark. Puncture vine (*Tribulus terrestris*), a more or less cosmopolitan weed in the warmer parts of the world, contains a photosensitizing agent and causes a disease, tribulosis, when eaten by animals.

China tree (*Melia azedarach*), a native tree of India widely introduced in many warm regions of the world, including the southern United States, contains a narcotic poison, especially in its fruits. Many species of spurge (*Euphorbia* sp.) native to Africa, Europe and America contain toxic substances in their latex. These plants are not only poisonous when eaten but many of them are poisonous to touch. Covillea (*Karwinskia humboldtiana*), a shrub native to Mexico and the southwestern United States causes a paralytic disease, "limberleg," when the leaves are grazed by cattle and sheep. *Styphium perforatum*, native to Europe but widely naturalized in North America, Australia and North Africa, contains a photosensitizing agent. This species and also *H. crispum* cause the disease osteoporosis or bighead in cattle and sheep.

Water hemlock (*Cicuta vrosa*), native to Europe, and *C. maculata* and *C. douglasii*, native to wet lands in eastern and western North America, contain a resinous substance, cicutoxin, especially in their roots.

Only a small piece of root may kill a cow. Poison hemlock (*Conium maculatum*) and fool's parsley (*Aethusa cynapium*), both native to Europe and naturalized in North America, contain alkaloids in their roots and seeds. Mountain laurel (*Kalmia latifolia*) and sheep laurel (*K. angustifolia*), two native evergreen shrubs of eastern North America, frequently cause death of cattle and sheep when they eat the leaves. Indian hemp (*Apocynum cannabinum*) and dogbane (*Apocynum androsaemifolium*), native to North America, produce a resinous material with toxic substances responsible for poisoning cattle and horses. Oleander (*Nerium oleander*) native to Asia but widely introduced in the warmer parts of the world, contains toxic glucosides. Various domestic animals have been poisoned by eating the leaves.

Whorled milkweeds (*Asclepias glaberrima*, *A. mexicana*) and related species native to western North America have caused death of sheep and cattle grazing on the tops. Black nightshade (*Solanum nigrum*) and European bittersweet (*S. dulcamara*) contain the alkaloidal glucoside solanine in the leaves and berries. Thorn apple (*Datura stramonium*) and related species, native to warmer parts of the world but now widespread, contain toxic alkaloids. Belladonna (*Atropa belladonna*) and henbane (*Hyoscyamus niger*), European species introduced into North America, are poisonous and are also grown as medicinal plants for their powerful alkaloids. Foxglove (*Digitalis purpurea*), native to Europe and naturalized in western

COURTESY NEW YORK COLLEGE OF AGRICULTURE AT CORNELL UNIVERSITY.
FIG 2.—MOUNTAIN LAUREL (*KALMIA LATIFOLIA*). (A) FLOWERING BRANCH. (B) FLOWER.

North America, contains several glucosides, mostly in the leaves. Animals, and rarely people, are poisoned by eating the leaves. White snakeroot (*Eupatorium rugosum*), native to eastern North America, causes the disease trembles in cows and milk sickness in people. Cocklebur (*Xanthium* sp.), widespread in warmer parts of the world, are poisonous in the seedling stages. Ragworts (*Senecio prostratus*, and other species) cause a disease of the liver in cattle and horses in North America, South Africa, parts of Europe and New Zealand.

(W. C. M.)

POISSON, SIMÉON DENIS (1781-1840), French mathematician, was born at Pithiviers in the department of Loiret on June 21, 1781. He studied medicine but gave it up in favour of mathematics. In 1798 he entered the École Polytechnique at Paris, where he attracted the notice of Lagrange and Laplace. Until his death on April 25, 1840, he was almost entirely occupied in mathematical research and in teaching. He was made *professeur suppléant* at the École Polytechnique in 1802, and full professor in succession to Fourier in 1806. In 1808 he became astronomer to the Bureau des Longitudes; and when the Faculté des Sciences was instituted in 1809 he was appointed *professeur de la mécanique rationnelle*. He was the author of more than 300 memoirs and papers. His most important work was on the application of mathematics to physics, and in particular to electrostatics and magnetism. In the field of pure mathematics, his most important works were his series of memoirs on definite integrals, and his discussion of Fourier's series, which paved the way for the classical researches of Dirichlet and Riemann on the same subject.

Besides his many memoirs, Poisson published a number of treatises *Traité de mécanique*, 2 vol., (1811 and 1833), which was long a standard work, *Théorie nouvelle de l'action capillaire* (1831), *Théorie mathématique de la chaleur* (1835); *Supplément* to the same (1837), *Recherches sur la probabilité des jugements*, etc. (1837).

See F. Arago, *Biographie de Poisson*, read before the Académie des Sciences on Dec. 16, 1850. It contains a list of works.

POISSY, a town of northern France, in the department of Seine-et-Oise, 17 mi WNW of Paris, on the railway from Paris to Rouen. Pop. (1946) 13,375. Poissy was the ancient *Pictacum*. The ancient church, dating from the 12th century and restored under E. E. Viollet-le-Duc, affords one of the earliest and best examples of transition from the Romanesque to the Pointed style. The old bridge of Poissy was widened and modernized. The painter J. L. E. Meissonier lived in the town.

POITIERS, a town of western France, formerly capital of Poitou (qv) and now the chief town of the department of Vienne, 61 mi SSW of Tours on the railway to Bordeaux. Pop. (1946) 48,546. Called *Limonium* at the time of the Roman conquest, Poitiers afterward took the name of its Gallic founders, the Pictones or Pictavi. Christianity was introduced in the 3rd cen-

FROM "POISONOUS PLANTS OF U.S.A." BY W. C. MUESCHER, THE MACMILLAN CO.
FIG. 3.—WOOLLY LOCOWEED (ASTRAGALUS HOLLISISSIMUS)

tury, and the first bishop of Poitiers, from 350 to 367, was St. Hilarius. Fifty years later the city had fallen into the hands of the Arian Visigoths and became one of the principal residences of their kings. Alaric II was defeated by Clovis at Vouillé, not far from Poitiers, in 507, and the town became a part of the Frankish dominion. This was the first occasion on which the peoples of northern and southern Gaul met in conflict near the town which was to see them so often join battle. By his victory in 732 over the Mohammedans at Mousais-la-Bataille in this region, Charles Martel proved the saviour of Christendom. Eleanor of Guenne frequently resided in the city and in 1199 entrusted it with communal rights. After the battle of Poitiers in 1356 (see below), Poitou was recognized as an English possession by the treaty of Brétigny (1360), but by 1373 it was recovered by Bertrand du Guesclin.

Between the northwest of the plateau central and the Gâtine, both heights of old rock, lies the relatively low land called the Seuil du Poitou, giving a historic connection between the Paris basin and the basin of the Garonne. In this lowland streams have dissected valleys in the Jurassic rocks, and Poitiers stands on a promontory above the junction of the Boivre and the Clain (a tributary of the Loire by the Vienne), its situation has given it a peculiar importance in military and political history. The town is picturesque, and its streets are interesting for their remains of ancient architecture, especially of the Romanesque period, and the memories of great historical events. Till 1857 Poitiers contained the ruins of a Roman amphitheatre more extensive than that of Nîmes, remains of Roman baths, constructed in the 1st and demolished in the 3rd century, were laid bare in 1877, and in 1879 a burial place and the tombs of a number of Christian martyrs were discovered on the heights to the southeast, the names of some of the Christians being preserved in paintings and inscriptions.

The cathedral of St. Peter was begun in 1162 by Henry II of England and Eleanor of Guenne on the ruins of a Roman basilica. It was completed by 1379 in the Romanesque and Early Gothic styles. The choir stalls (1235-57) are among the oldest in France. The church of St. Jean near the cathedral is the most ancient Christian monument in the country. Built as a baptistry in the first half of the 4th century, it was enlarged in the 7th century.

The church of St. Radegonde, a great resort of pilgrims, commemorates the consort of Clotaire (d. 587), preserving in its crypt the tomb of Radegonde, who founded at Poitiers the abbey of the Holy Cross, and two others reputed to be those of St. Agnes and St. Discola. The choir and tower above the entrance are of the 11th century, while the nave (late 12th century) was built in the Angevin style. Notre-Dame la Grande (late 11th century) represents a much older collegiate church and has a richly sculptured Romanesque façade. The church of Montierneuf (*Monasterium Novum*) was begun in 1077 by William VI, duke of Aquitaine and count of Poitiers, who was buried within its walls, and the choir (13th century modified by the erection of a "lantern") was solemnly consecrated by Urban IV in 1266. Restorations were effected in the 19th century. The beautiful 11th-century tower of St. Porchaire was restored in the 19th century.

Poitiers has a university with various faculties. Trade is in farm produce, wine, wool, honey, goose quills and leather. The industries include the preparation of goose and swan skins, printing and the manufacture of hosiery, brushes, oil, paint and candles.

Counts of Poitiers.—In the time of Charlemagne the county of Poitiers, then part of the kingdom of Aquitaine, was represented by a certain Abbon. Renoul (Ranulph), created count of Poitiers by Louis the Pious in 839, was the ancestor of a family distinguished in the 9th and 10th centuries for its attachment to the Carolingian dynasty. One of his successors, Ebles the Bastard (d. 935), took the title of duke of Aquitaine, and his descendants retained the hereditary name of William. In accordance with the dying wishes of William X his daughter Eleanor was married in 1137 to Louis, the son of Louis VI of France. Sole heiress, she brought her husband Poitou, Saintonge, Anjou, a part of Touraine and Berry, Marche, Angoumois, Périgord, Auvergne, Limousin,

Bordeaux, Agenois and Gascony After a divorce in 1152, Eleanor married the count of Anjou, Henry Plantagenet, who became king of England as Henry II The west of France thus passed into the hands of England Philip Augustus reconquered Poitou in 1204 When Charles VII ascended the throne he united the countship of Poitiers to the crown

BATTLE OF POITIERS

The battle of Poitiers, which was fought on Sept. 19, 1356, between the armies of King John of France and of Edward the "Black Prince," was the second of the three great English victories of the Hundred Years' War From Bordeaux the Black Prince had led an army of his father's Guenene vassals, with which was a force of English archers and men-at-arms, into central France and had amassed an enormous booty King John, hitherto engaged against the army of John of Gaunt, duke of Lancaster, in Normandy, hurried south to intercept the raiding army and to bar its homeward road After an unexpected encounter with the French rear, the Black Prince, by forced marching, was able to slip past the French, but reaching Maupertuis, 7 mi S E of Poitiers, with the king's army in chase, he found himself compelled to choose between fighting and abandoning his spoil He chose the former course, in spite of the enemy's great superiority in numbers (perhaps 16,000 to 6,500), and in order to give his trains time to draw off took up a defensive position on Sept. 18 with a slight hollow in front and a wood behind, between the Poitiers-Bordeaux main road and the Maussou river John, instead of manoeuvring to outflank the English, allowed the cardinal Helie de Talleyrand-Perigord to attempt to negotiate a peace This proving vain, the French army attacked without any attempt at manoeuvre or reconnaissance, and on a front so narrow that the advantage of superior numbers was forfeited Moreover, King John ordered all but the leading line to dismount and to attack on foot (tactics suggested by the success on the defensive of the dismounted English men-at-arms at Crécy and the Scots at Bannockburn), and thus condemned the best part of his army to a fatiguing advance on foot across difficult country in full armour

The French crossbowmen, who might have crushed the relatively few English archers present, were mingled with the mounted men in first line, but, as the latter charged, their advance masked the fire of the

then resumed his march to Bordeaux, making no effort to exploit his military ascendancy And in this he was justified, for he had now in his hands a political key which could yield him all the possible profits of victory, without their military cost

POITOU, a former province of France, roughly corresponding to the modern departments of Vienne, Deux-Sèvres and Vendée The Seuil du Poitou is a low-lying zone of sedimentary rocks, about 60 mi wide, separating two higher countries of older rocks (Limousin in the east, the southern part of the Massif Armoricain in the west) and forming the easiest natural passage between northern and southwestern France

Poitou, which takes its name from the Gallic Pictavi or Pictones, was incorporated by the Romans into Aquitania and was for centuries the northern part of Aquitaine (qv) and, as such, a border country and a battlefield (Vouillé, 507, Poitiers, 732 and 1356, Moncontour, 1569) as well as the meeting place of northern and southern cultures Its golden age (11th-12th centuries) is represented by a great school of Romanesque architecture, sculpture and painting (Saint-Savin) Philip Augustus occupied it in 1204, and the treaty of Paris (1259) recognized the French conquest, after which Poitou was subject to the royal authority (except for a few years after the treaty of Brétigny) From 1417 it was a stronghold of the dauphin Charles, who made Poitiers his capital much more than Bourges Poitou suffered much in the Wars of Religion, its later history was much quieter, apart from the insurrection of the Vendée against the Revolutionary government

BIBLIOGRAPHY—G Chagnolleau *et al*, *Visages du Poitou*, 2nd ed (Paris, 1946), R. Crozet, *Histoire du Poitou* (Paris, 1949), and *L'Art roman en Poitou* (Paris, 1948) (F Cr.)

POKEBERRY or **POKEWEED**, the popular name (from the American Indian *pocan*, applied to any plant yielding a red or yellow dye) of *Phytolacca decandra*, a strong-smelling perennial herb, a native of North America, with ovate-lanceolate sharp-pointed leaves, racemes of small greenish-white flowers and flat-tish berries nearly $\frac{1}{2}$ in in diameter, which contain a crimson juice The young asparagus-like shoots are sometimes used as a potherb, but the roots are poisonous The plant is often cultivated in Europe, and has become naturalized in the Mediterranean region.

POKER, a card game played in various forms throughout the world In the English-speaking countries it is exceeded in popularity only by contract bridge and, in the United States, rummy

In principle poker is an ancient game, almost as old as playing cards themselves, but its name and present form originated in the United States early in the 19th century R F Foster, Scots-born U S student of games, cites an 1834 reference to poker, and no earlier one is known There has since been gradual but continuous change in the form of the game

Poker has countless variants and probably in no two poker games is exactly the same procedure followed, but the fundamentals are constant and one who knows them can easily play in any game

A standard pack of playing cards is used, consisting of 52 cards divided into four suits: spades (♠), hearts (♥), diamonds (♦) and clubs (♣), the suits having no relative rank, each suit has 13 cards ranking ace (high), king, queen, jack, 10, 9, 8, 7, 6, 5, 4, 3, 2 (low) From two to eight players ordinarily participate, taking their seats at random around a table

The object of the game is to win money (or chips or other tokens), for which poker is invariably played, by having the highest-ranking "hand" of five cards, or by "bluffing"—making the other players believe one's hand is best even though it is not The rank of poker hands is based upon the relative infrequency of the combinations which have value. These are, from highest to lowest:

Straight flush five cards of the same suit and in sequence. The ace, king, queen, jack and 10 of one suit are a "royal flush." The ace may also rank low in the sequence 5-4-3-2-ace

Four-of-a-kind, as, all four 6s and any fifth card

Full house, or *full hand* three of one kind and two of another, as 10-10-10-3-3

Flush five cards of the same suit

Straight five cards in sequence, but of two or more suits The ace ranks either high or low, as in a straight flush.

men Had the third body of the French advanced with equal spirit the battle would probably have ended there and then, but the duke of Orleans, who commanded it, was so demoralized by the retirement of the dauphin's division that he led his whole force off the field without striking a blow

Thereupon the king himself advanced furiously with the fourth and last line, and as it came on, the situation of the English seemed so desperate that the prince was advised to retreat But his determined courage was unshaken, seeing that this was the last attack he put his reserve into line, and, rallying around this nucleus all men who could still fight, he prepared not only to repulse but to counterattack the French He dispatched 60 men-at-arms and 100 archers under the Captal de Buch to ride round the flank of the enemy and to appear in their rear at the crisis of the fight Though a mediæval knight, he knew as well as Napoleon at Arcote that when the moral force of both sides has passed its culminating point even a materially insignificant threat

¹The view adopted is that of Sir Charles Oman, *Art of War in the Middle Ages*, AD 378-1485, p 631 (1924).

Three-of-a-kind, or triplets, with any two other cards.
Two pairs, as, A-A-9-9 and any fifth card
One pair

As between two hands having combinations in the same category, the winner is determined as follows

Straight flushes, flushes, straights or no pair the one containing the highest card wins, if these cards are identical in rank, the next highest decides, and so on. *Four-of-a-kind or three-of-a-kind* the one composed of the higher-ranking cards. *Full house* the higher three of a kind. *Two pairs* the highest pair, if these are identical, the higher of the second pairs, if these are identical, the higher of the two unmatched cards. *One pair* the higher pair, if these are identical, the highest of the unmatched cards, and so on.

If two hands are identical they tie

The better of these combinations occur infrequently. There are 2,598,960 possible poker hands, of which 40 are straight flushes, 624 four-of-a-kind, 3,744 full houses, 5,108 flushes, 10,200 straights, 54,912 three-of-a-kind, 123,552 two pairs, 1,098,240 pairs and 1,302,540 with no pair or better. To increase one's chance of holding a good hand, in some games value is accorded to one or more of the following special hands, ranking as follows

Big tiger, or big cat king high, 8 low, no pair

Little tiger, or little cat 8 high, 3 low, no pair.

Big dog ace high, 9 low, no pair

Little dog 7 high, 3 low, no pair, any tiger or dog beats a straight but loses to a flush

Skip straight, as 2-4-6-8-10, or *round-the-corner straight*, as queen-king-ace-2-3, beats three-of-a-kind, loses to a straight

Blaze five "face cards"—kings, queens and jacks. Beats two pairs, loses to three-of-a-kind

Four-flush (played only in stud poker) four cards of the same suit; beats a pair, loses to two pairs

As between two skip or round-the-corner straights or two four-flushes, the highest card decides. As between special hands in any of the other categories, ties are not broken

The Shuffle and Deal.—Any player deals the cards in rotation to his left, one at a time face up, until a jack shows, the player receiving the jack becomes the first dealer. Any player may then shuffle the cards, the dealer last; the player at the dealer's right may cut or not, as he pleases, and the dealer serves the cards, one at a time, face down, in clockwise rotation beginning with the player at his left. The right to deal will then pass from player to player to the left

The most popular variants of poker are:

Draw poker, the game as played in Great Britain and to some extent in the United States, where it originated. Five cards are dealt to each player. The "age"—player at the dealer's left—must make the first bet, called an "ante." All bets go into the centre of the table and form a "pot." A limit is placed on the size of bets, the ante is commonly 10% to 25% of this limit. The next player in rotation may "straddle" (put up double this ante) but must do so "blind" (without looking at his cards). Each player in turn after the ante or straddle may then "call" or "see" by betting the same as the player before him; or may "raise" by calling the previous bet and adding an additional bet to it, or must "drop" out of the pot and discard his hand

When every player has exactly called the last previous bet or raise, or has dropped, each active player in turn beginning with the age may discard one, two or three cards, which the dealer replaces, face down, from the top of the deck. This is the "draw." A player who does not wish to draw is said to "stand pat." The dealer may not serve the last card. If necessary the discards must be shuffled and cut to complete the draw. To avoid this, most draw poker games are limited to seven players.

The active player nearest the left of the age (or of the straddler, if any) must now bet or drop, and so on around until the last previous bet or raise has been exactly called by every player still in the pot. There is then a "showdown," in which the player who made the last bet and each player who called it must place his five cards face up on the table. The highest-ranking hand wins the pot. If no one called the last bet, that bettor wins and need not show his hand

Jack pots is the favourite U.S. draw-poker variant. Each

player antes before the deal. The ante usually is about 5% of the limit. Five cards are dealt, face down, to each. Beginning at the dealer's left, each player in turn may pass or open. To open, a player must have a pair of jacks or any better hand. If no one opens, everyone antes again and the deal passes. If the pot is opened, each player in turn (whether or not he previously passed) may either call, raise or drop. (In other poker variants, however, the term "pass" is equivalent to "drop," and a player who once passes may not re-enter the pot.)

After the draw, any active player, beginning with the one who opened, may bet or may "check"—stay in the pot without betting—until a bet is made, thereafter, each player in turn must either call, raise, or drop. If everyone checks, or when everyone has called the last bet or has dropped, there is a showdown. The opener, to win the pot, must demonstrate that he had "openers." A penalty is usually prescribed for a false opening—usually that the offender must ante for everyone on the next deal.

Stud poker is the most popular of the poker variants played for high stakes in the United States. As many as 14 have been known to participate in a single stud-poker game, but 7 to 9 make the best game. The dealer gives each player one face-down card, called the "hole card," and then one card face up, whereupon the deal is suspended for a round of betting. The player dealt the highest card must make a bet, of identical cards the one dealt first (i.e., nearest the dealer's left) ranks higher. Each player in turn thereafter must call, raise or drop. (To drop, he turns down his face-up card or cards.) When this round of betting is completed, each active player receives another face-up card, and there is another round of betting, and this process is repeated until each player has in all five cards, one of them his hole card. On each of the last three rounds of betting, the player having the highest-ranking combination showing bets first, and may bet or check as in jack pots. After the last round of betting there is a showdown in which the hole cards are shown and the highest-ranking hand of five cards takes the pot.

Seven-Card Stud.—Each player receives two hole cards face down, then four cards face up, with a round of betting after each, then one more card face down and another round of betting. At the showdown each player selects five of his seven cards as his hand.

High-Low Poker.—The highest-ranking poker hand and the lowest-ranking poker hand divide the pot equally. If there is an odd chip the high hand gets it. If two or more hands tie for high or low, they split their half of the pot equally.

High-low seven-card stud became a fad game in the United States in the early 1930s, and is perhaps the most scientific of the poker games. Seven-card stud is played, and at the show down the high and low hands are to split the pot; but each player may select five of his cards as a high hand, and five as a low hand, and perhaps thus win the entire pot. Some play that the ace may count as either the high or the low card in this game, so that the lowest possible hand is 6-4-3-2-ace of two or more suits. "Table stakes" are usually played in this game, as in any poker game for high stakes, the limit for each player is the amount he has on the table at the time.

Wild Cards or "Freaks."—A "wild" card may stand for any card its holder wishes to name. A 53-card pack, including a joker as a wild card, is often used; or the four deuces (2s) may be called wild (in which case the game is called "deuces wild"). "Naturals" are usually played to beat equivalent wild-card combinations, so that three aces will beat one ace and two wild cards. When wild cards are played, the highest possible hand is five-of-a-kind. Serious players scoff at most wild-card variants, but some use the "bug"—the joker used either to represent an ace or to fill a flush or straight. Thus, A-A-bug-6-5 represent three aces, and 8-7-6-bug-4 are a straight, but K-K-bug-6-5 are only a pair of kings.

Irregularities in Poker.—There are no official poker rules. The following remedies are more or less generally applied to irregularities in serious games.

Misdeal. None. If a player at any time has more than five cards or fewer than four, his hand is dead. If a player is dealt four cards, and

does not look at any of them, the dealer must complete his hand after finishing the regular deal. An error in the draw may be corrected only before the next player in turn has drawn.

Betting rules Money once put in the pot may not be removed. A bet out of turn remains in the pot, and when the player's turn comes he may increase it enough to make it constitute a call or raise. An announced bet is not valid until the money is in the pot.

Exposed card During the deal, a player must take it. During the draw, an exposed card is dead and is replaced after the regular draw is completed.

Announcements out of turn If a player announces out of turn that he intends to drop, but keeps his hand, or announces an intention to bet, but does not put the money in the pot, the announcement is meaningless and in turn he may act as he pleases.

Skilful Play—Poker better rewards skilful play than any other card game. Psychology and the "poker face" do not, however, play so great a part in its science as is generally supposed. Patience—the ability to drop time after time until a good hand comes along—is a prime ingredient of the successful poker player. Even more important is the good player's insistence on receiving proper "odds" for every bet he makes. It is 8½ to 1 against improving three-of-a-kind by drawing two cards, and 11 to 1 against improving two pairs by a one-card draw, but these hands are so often good enough to win without improvement that it is generally wise when holding them to raise before the draw. It is 2½ to 1 against improving a single pair by drawing three cards, a pair lower than queens should usually be dropped and no single pair justifies a raise. The odds are 38 to 9 against making a flush by drawing one card to a four-flush, and 39 to 8 against "filling a bob-tail straight" (open at both ends, as 10-9-8-7), so these hands should be dropped unless there is at least five times as much in the pot as it would cost to stay in. An "inside straight" (such as 10-9-7-6) should not be played in any circumstances. In stud poker it is unwise to stay unless one's cards, including the hole card, will "beat the board" (that is, are better than any showing combination of cards); and in no case should one stay against an "open pair" (a pair showing in another player's face-up cards) unless holding a higher pair.

See *Oswald Jacoby on Poker* (1940) for the game as played in the U.S., Maurice Ellinger, *Poker* (1944), for the game as played in England. (A H Mo)

POKOMAM, a group of Indians speaking a Maya dialect who live in southern Guatemala. Their territory runs from the upper part of the Motagua river to the border of Salvador. They inhabit the departments of Chimaltenango (in part), Guatemala, Amatitlán and Jalapa in Guatemala, and at the time of the conquest they extended to Chalchuapa in Salvador. The principal towns where this tongue is spoken are San Martín Jilotepeque, Mixco, Petapa, Jalapa, Jilotepeque and Asunción Mita. They number about 50,000, of whom more than half speak their native tongue. The ancient capital of the Pokomam was the fortress of Mixco situated on a steep hill in the valley of Xilotepeque.

POLA, a seaport of Italy, the capital of the province of Pola, in the district of Venezia Giulia, 86 mi S of Trieste by rail. Pop. (1936) 34,090 (town), 42,259 (commune). It was the principal naval harbour and arsenal of the Austro-Hungarian monarchy until 1918, and is situated near the southern extremity of the peninsula of Istria. It lies at the head of the Bay of Pola, and possesses a safe and commodious harbour almost completely landlocked. An extensive system of fortifications, constructed on the hills which enclose the harbour, defends its entrance, while it also possesses a good roadstead in the large channel of Fasana.

The modern town of Pola lies round the base of a hill formerly crowned by the Roman capitol, and now by a castle of the 17th century. Besides the castle the chief buildings are the cathedral, burned down in 1923 and reconstructed on the lines of a 6th-century Ravenna basilica, the new garrison church, completed in 1898 in the basilica style, with a marble façade, and the Franciscan church dating from the 14th century. To the southwest, along the coast, extends the marine arsenal, which has been dismantled, the large barracks are equally deserted. The chief interest of Pola centres in its fine Roman remains. The most ex-

tensive of these is the amphitheatre built in A.D. 78-211 in honour of the emperors Septimius Severus and Caracalla, which is 79 ft high, 400 ft long and 320 ft wide, and could accommodate about 23,000 spectators. It is remarkable as the only Roman amphitheatre of which the outer walls have been kept intact. The history of Pola begins with its capture by the Romans in 178 B.C. It was destroyed by Augustus because of its espousal of the cause of Pompey, but was rebuilt under the name of Pietas Iulia and was mainly important as a harbour. Later it became the capital of the margraves of Istria, and was captured by the Venetians in 1148. In 1379 the Genoese, after defeating the Venetians in a great naval battle off the coast, took and destroyed Pola, which disappears from history for the next 450 years. It remained under Venetian supremacy to 1797, and fell under Austria in 1815. See T. G. Jackson, *Dalmatia, the Quarnero and Istria*, vol. xi (1887).

POLABS (*Polabian*, *Polabian*), the Slavs (*q.v.*) who dwelt upon the Elbe and eastward to the Oder. Except the Lithuanians they were the last Europeans to be Christianized, their chief sanctuary was at Arcona on the Isle of Rugen. They were converted and conquered in the 12th century and germanized. By the 17th century Slavonic survived only in a tiny patch in the east of Hanover about Luchow, its scanty remains are corrupt.

POLAND (POLSKA), a country of eastern Europe lying between the Baltic sea to the north and the Sudeten and the Carpathian mountains to the south and bounded, from 1945, on the east by the U.S.S.R., on the south by Czechoslovakia and on the west by Germany. (For population, see below.)

PHYSICAL GEOGRAPHY

The main morphological features have been moulded by two great influences: the northward thrust of the alpine fold mountains against the Hercynian plateaus (represented there by the Bohemian massif and the submerged Polish platform which reaches the surface in the Lysagora) and the southward sweep of the Scandinavian ice-sheet. Conditioned by these influences the natural regions tend to form zones running broadly east and west across the country.

In the extreme south, the mountain frontier zone is divided into two sections. The first, composed of the older, much penetrated rocks of the Sudeten mountains, reaches its highest point in Mt. Śnieżka (5,266 ft.), the second, formed by the young fold mountains of the Carpathians, assumes a truly alpine appearance in the High Tatras, the highest point of which, Gerlachovka (8,737 ft.), lies across the frontier in Slovakia. The submontane zone of southern Poland, consisting of upland-rimmed river basins interconnected by narrow gateways, is again capable of subdivision. Thus Silesia, drained northwestward by the Oder, forms a unity centring upon Wrocław (Breslau), bounded on the north by the Trzebnica hills, this basin represents an extension of the great carboniferous deposits of northwestern Europe. The sub-Carpathian basins, on the other hand, occupy a tectonic hollow running from the Moravian gate through the small Oświęcim basin and the Cracow gate to the wide Sandomierz basin drained by the Vistula and San, with the Przemyśl gap separating the latter from the headwaters of the Dniester, within the Soviet frontier. The Little Polish tableland which separates the Silesian and sub-Carpathian basins, consists of the Cracow-Częstochowa limestone plateau (1,653 ft.), opening southeastward to the Tertiary deposits of the Nida basin, and the Holy Cross (Świętokrzyskie) mountains (Lysagora, 2,004 ft.). The southeastern edge of the latter, the level Sandomierz tableland, is noted for its fertile loess deposits. Finally, east of the Vistula the upland rim is represented by the Lublin tableland, with its rich soils derived from chalk marl, and the Rostoczek ridge.

The remainder of Poland is dominated by glacial features. The characteristic east-west sectors of the great rivers and their tributaries (e.g., the lines formed by the Bug-Vistula-Notec-Warta and the Warta-Obra-Oder) mark stages in the successive northward retreat of the ice sheet, when drainage was forced toward the west. Central Poland, an undulating country crossed by the great valleys, is subdivided into the Great Polish and Kujavian lowlands around Poznań and the Mazovian Podlaskian lowlands

around the capital city, Warsaw. The soils are based on fluvio-glacial and fluvial deposits. Further north, breached by the Oder and Vistula in their lower courses, lies the Baltic lake zone, Pomorze (Pomerania) to the west and Mazuria to the east of the Vistula. It is a region of classic moraine topography: the boulder clay, sands and gravels form hummocky ridges, reaching often more than 650 ft in height and interspersed with numerous lake-filled, peaty hollows. The moraine hills descend to a low sandy plain along the Baltic coast. The half-formed deltas of the Oder and Vistula are classic examples of the lagoon-and-bar coastal formation, where the sea currents and prevailing winds drag the river deposits and coastal sands eastward along shore. Modern methods of port maintenance and navigation enabled the old ports to continue their ocean-going trade.

Flora and Fauna.—The natural forests of Poland are transitional between the mainly coniferous stands of northern Europe, closely associated with the podzols, and the deciduous woodlands of central and western Europe growing on the more fertile brown soils. The fauna is that associated with the temperate forests which once covered most of the country apart from the alpine zone of the high mountains. The reindeer, sable and wild horse, however, survive only in tradition, the bear is restricted to the Carpathians, the elk was found in the former northeastern provinces and the beaver in the Polesian marshes, which became Soviet territory.

About 70% of Poland's forests are coniferous, with the pine dominant, followed by spruce. There are few firs, while larches and yews appear only sporadically. The deciduous trees, more characteristic of the southern provinces, are mainly birch, beech, wych-elm, aspen, ash, oak and alder. One of the best-known forests is that of Białowieża, famed for its ancient trees and, up to 1918, its herd of aurochs or European bison (later crossbred with animals of Canadian origin). The main timber products are deal boards, building timber, pit props and fuel. Losses incurred in World War II made it necessary to import certain types of timber, whereas before that war the export of timber accounted for one-fifth of the active foreign trade balance.

Climate.—Climatically, Poland belongs to the major zone which includes eastern Germany, most of Finland and western USSR. It is open to the influence of the prevailing, variable westerly winds, except when these are replaced during winter by the heavy masses of cold air cushioning the interior of the continent. The summers are warm or very warm, according to distance from the sea and latitude, although the latter is offset by the increasing height of the land toward the south. The winters are cold and are particularly unpleasant when pressure conditions are right for the influx of strong winds from the Russian plains. Temperatures are everywhere below freezing point for at least two winter months in the west and three months in the east. The Oder, for example, is frozen for an average of 80 days, the Vistula 80–100 days; and the Baltic harbours, especially where distant from the open sea, are icebound for a considerable period every year.—Świnoujście for 20 days on the average, Szczecin for 61 days. The open Baltic itself is frequently impeded by drift ice, but navigation usually continues along the sea lanes connecting the favourably placed docks of Gdynia-Gdańsk (Danzig). The following figures for the mean January and July temperatures, in degrees Fahrenheit, are typical: Szczecin, 30.4 and 64.9; Warsaw, 26.8 and 65.5; Tomaszów Lubelski, 23.9 and 64. Sniezka, with a range between 19.2 and 46.9 and below freezing point for six months, is typical of conditions in the highest mountain regions, even in the Tatras, however, there are no permanent snows.

Precipitation, in winter mostly in the form of snow, is moderate, 20–27.5 in., except along the southern highland fringe. More falls in the summer half-year, because of the development of thundery conditions in early summer and of the passage of depressions in autumn. The skies are on the whole cloudy, mean cloudiness averaging somewhat less than seven out of ten points; the summers are brighter and less humid, although more rainy, than the winters. Wrocław is representative, with a mean annual rainfall of 23.3 in. and cloudiness of 6.8 points; precipitation is distributed seasonally, in percentages of the total, beginning with

winter, as follows: 16, 24, 38 and 22. Sniezka has a mean annual precipitation of 45.6 in., typical of the narrow mountain fringe.

BIBLIOGRAPHY.—E. de Martonne, "La Pologne," in part 2 of *Europe centrale*, vol. IV of *Géographie universelle*, ed. by L. Gallois and P. Vidal de la Blache (Paris, 1931); W. Nalkowski, *La Pologne, essai géographique* (Paris, 1926).

HISTORY

Polish history begins in the year 963 when a German border knight came into contact with Mieczysław or Mieszko I, who was prince of Poland till 992. The unity of the Polish state, surrounded as it was by other pagan and mostly Slavonic tribes, had been achieved under the descendants of Piast (said to have been either of peasant origin or an official at the court of an older dynasty), who founded the dynasty which gave his people strong and valiant rulers down to 1370. Mieszko's predecessors had succeeded not only in uniting a number of tribes but in establishing a highly developed political community which had neither enjoyed the benefits nor suffered the disadvantages of contact with the high civilizations of western and southern Europe. To meet the dangers that arose when the Germans began to penetrate the barrier formed by the western Slavonic tribes, Mieszko conceived that policy of deliberately adopting western civilization which was the chief object of the rulers of Poland for several centuries. He secured his state from the aggression of his new neighbours by acknowledging himself a tributary of the western emperor Otto I, and removed all danger of a hostile crusade by accepting Christianity for himself and for his people in 966 with the help of the Czech princess Dąbrowka or Dabrowka, whom he had married a year before. Finally he placed all his lands in the hands of the pope, thus inaugurating a close relationship that gave Poland the special protection of the Holy See. He seems to have been successful in gaining Pomorze (Pomerania, *see* the seaboard), but lost part of his eastern territory to Vladimir the Saint.

THE PIAST KINGDOM

Mieszko's son Bolesław I the Mighty (*see* BOLESŁAW I) (992–1025) was one of the great soldiers and statesmen of his time. From the congress of Gniezno (Gnesen) (1000) with his friend the emperor Otto III, where he secured for Poland an independent church, organized in a number of bishoprics under a metropolitan at Gniezno, to his coronation as king (1024), he achieved the transformation of his father's principality into a powerful and independent kingdom. His wars of defense and expansion against Germany and Bohemia ended successfully in 1018, then he turned east and occupied the Russian capital, Kiev, thus recovering the territory lost in the preceding reign. His younger son Mieszko II (1025–34) succeeded him as king, but the power of the kingdom waned in spite of its partial revival under Mieszko II's son Casimir (Kazimierz) I the Restorer (1038–58) and the strong rule of Casimir's son Bolesław II the Bold (*see* BOLESŁAW II) (1058–79). But under Bolesław III Wrymouth (*see* BOLESŁAW III) (1102–38), a nephew of Bolesław II, Poland made great advances. Bolesław maintained the independence of his country when the emperor Henry V invaded Silesia in 1109 by a victory at Głogów. His reign saw a considerable cultural advance, and an anonymous chronicler recorded the earlier history of Poland. He collaborated with Otto, bishop of Bamberg, in converting the Pomeranians to Christianity and occupied the greater part of that province.

The Period of Division, 1138–1314.—Bolesław III divided Poland among his sons, so that Poland, like its neighbours Germany and Kievian Russia, ceased to be a united state for two centuries. The capital was established at Cracow, the ruler of which held the central provinces of Poland together with Pomorze and had "seniority" over his brothers, who ruled over Silesia, Mazovia, Great (or western) Poland and Sandomierz. In each of these principalities there grew up round the Piast prince a powerful upper class consisting of the officials and the clergy headed by the local bishop, a process which modified the *ius ducale* of the monarchical system. This period of divided loyalties laid the country open to many dangers, while the empire remained strong, a ruler like Frederick I Barbarossa in 1157 could assert his claim to Polish allegiance, and a major disaster like the Mongol

invasion in 1241 found the chivalry of Little (or southern) Poland unsupported and the heroic efforts of Prince Henry of Silesia made in vain. Worst of all were the incessant raids of the barbarian neighbours, notably the Lithuanians and Prussians. To avert these, Prince Conrad of Mazovia called in the Teutonic Order, a purely German crusading organization that had lost a sphere for its activities in Palestine. Well established on the northern border, the order was helped by the Poles to occupy not only the borderland but the whole of Prussia, which was speedily colonized mainly by German immigrants. By a brilliant piece of diplomacy the grand master Hermann von Salza persuaded the emperor Frederick II to accept his homage as ruler of the newly acquired lands (1226). The divided Polish states found themselves face to face with a powerful German state on their northern border.

In spite of the political weakness of Poland, of the great Mongol disaster and of the menace from Germany, this age was one of great importance to the development of Poland. In the process of decentralization, each province was able to assert its own individuality, helping its prince and bishop to enlarge its capital city and to intensify their efforts to develop the resources of its small territory. The petty princes were able to imitate western Europe by encouraging the immigration of German peasants, townsmen and artisans, who helped them to raise the level of economic life. The ideal of the 13th-century Polish prince, especially in Silesia, was *melioratio terrae*, to achieve which he was prepared to sacrifice both part of his own sovereign power and vague national ideals. This lack of a Polish patriotism resulted in the loss to Poland of some areas. Lower Silesia and western Pomerania were gradually colonized by Germans. But the economic and cultural advance of the country as a whole was worth the sacrifice. The community thus strengthened was able to maintain its ethnical frontier in spite of political disaster for six centuries. In most of Poland the Germans were ultimately absorbed. The princes further reduced their sovereign power by the granting of charters to different groups and individuals. The Jews, whom crusading zeal had expelled from nearly every country, were granted the right to settle in Poland, to maintain their own schools and to practise their religion. For the Poles they were skilled middlemen who made an important contribution to the economic life of the country but who were never absorbed as the Germans were and hampered the formation of a Polish middle class. The achievements of this period of division, in spite of its difficulties and weaknesses, can be appreciated through a comparison of the low social and economic situation in the 12th century with the resources available to the revived monarchy after 1305, whereby the rulers were able to reunite the divided principalities and to preside over the rapid development of a state that had no need to copy the social and economic life of its neighbours.

Wladyslaw I, 1314-33.—The idea of reuniting the Polish principalities in one state first appears in the experiments of the princes of Silesia, especially in those of Henry I the Bearded. These princes failed partly because they gradually succumbed to the attraction of German civilization and joined the empire under Czech auspices. Przemyslaw II of Great Poland actually assumed the royal title in 1295, but the real task of reunion was undertaken, at a time when Poland had come under the rule of Czech kings, by the hard-fighting Wladyslaw Lokietek (Ladislas the Short) (see WLADISLAUS) of Kujavia. The idea was strongly supported by the ecclesiastical leaders. These men had represented for a long time the links that bound Poles together and led the enlightened magnates who realized that a divided Poland would suffer extinction at the hands of such powerful neighbours as Bohemia, Brandenburg, Hungary and the Teutonic Order. Wladyslaw cleverly availed himself of the support of Hungary and of the traditional protection of the Holy See. After occupying Little Poland in 1305 and Great Poland in 1314, he was crowned king of Poland in 1320 as Wladyslaw I (1314-33). He had many disappointments, the Teutonic Order seized Pomerania in 1308, his country long continued to suffer from the raids of the pagan Lithuanians, and he never reigned over Silesia or Mazovia, which preferred to do homage to John of Bohemia. But he held his own

against the order in the battle of Plowce (1332), strengthened his position by his diplomatic friendship with Hungary (which was sealed in 1320 by his daughter Elizabeth's marriage to the new Angevin king Charles I) and ended for a time the Lithuanian raids by marrying his son Casimir to Anne (Aldona), daughter of the grand duke Gedymin, in 1325.

Casimir III the Great, 1333-70.—Unlike his father, Casimir was born in the purple and was a man of peace. A realist and a shrewd diplomatist with a zest for the Latin culture that he learned at the court of his sister in Hungary, he was ready to make great sacrifices to secure the independence, unity and prosperity of his kingdom. Happily for Poland the decline of the empire, the disunity of Germany, the weakness of Russia and the death of the last great khan of the Tatars lessened the dangers on the western and eastern frontiers. Poland had to face in the south the powerful kingdom of Bohemia, whose king in 1355 was crowned emperor as Charles IV, and in the north the great military strength of the Teutonic Knights. Basing his foreign policy on a close alliance with Hungary, he was content to allow Charles IV, another lover of peace, to hold Silesia, and to give up his claim to Pomerania and the border districts held by the order. As compensation for this loss of Polish territory, he found himself able by inheritance and diplomacy to annex Halicz and to begin that policy of conciliation with the Lithuanian princes which was to bring such important results later on. His own prestige grew abroad, and he made Poland a full member of the European community. By thus gaining for Poland a long period of peace and security, he was able to make great changes in the internal relations of the country. He codified the laws of Great and Little Poland and succeeded in persuading these two rival states to co-operate, while the local officials of Little Poland became national ministers. The princes of Mazovia were persuaded to acknowledge Casimir as their king. He acquired great wealth, reformed the currency and introduced western methods in town and country. He befriended the Jews, improved the position of the peasants and encouraged the immigration of Germans and Armenians, so that the cities grew in size and prosperity, especially Cracow and Lwow. He was a great builder and was said to have "found a country of wood and left a country of stone." The administration was made more efficient, and it was mainly to train young men in law that Casimir founded the University of Cracow in 1364. He encouraged learning and was able, through the Italian influences at the court of Hungary and the French connections of Prague, to raise the level of learning among the Poles to western European standards. By his foresight, his patience and genius for creation and adaptation, this great statesman made possible the strong and prosperous position of the Polish kingdom during his lifetime and its great development in the next two centuries.

Louis I of Hungary, 1370-82.—Having no sons, Casimir III bequeathed his kingdom to his sister Elizabeth's son Louis I of Hungary (1370-82), already one of the leading rulers of central Europe, who continued the co-operation of his two realms in the spirit of his predecessor. Like Casimir, he left no sons, and the future of central Europe depended to some extent on the fate of his two daughters. After an interregnum of two years the Poles accepted his younger daughter Jadwiga as their queen (1384-98) and consummated the efforts of Casimir III to conciliate the pagan rulers of Lithuania by arranging the marriage of Jadwiga to Jagiello, grand duke of Lithuania, who became king of Poland as Wladyslaw II (1386-1434).

Social and Constitutional Development, 1138-1384.—The social structure of the Polish state at the time of the dynastic union with Lithuania was very different from what it had been under the early kings. In the period of division there had grown up round each prince a class of ecclesiastical and lay magnates whose function was at first to advise and later to share with the prince the government of his principality. In addition to this privileged class, the general mass of the gentry, organized in their clans, each with its coat of arms and slogan, was becoming conscious of its own importance as a social and political element in the country. As the prince gradually lost his monopoly of political and legal power by the grant of charters to various groups, this

body, which came to be called the *szlachta*, began to share political privileges with the magnates. The extinction of the Piast dynasty gave them the opportunity by the pact of Koszyc (Kosice) in 1374 to obtain from Louis a number of privileges, the *magna carta* of Poland. The chief of these was the right to pay no taxes beyond a certain sum unless they had expressly consented to them. During the period of division the church which had established its position at the synod of Leczyca in 1180, played a leading part, not only in the social and moral life of the community but also as the sole factor of unity between the numerous principalities. The inhabitants of the towns had received charters mainly under Magdeburg law to encourage the settlement of Germans. Besides Wrocław (Breslau) and Poznań, the two great cities Cracow and Łwów grew to prosperity on the great eastern trade route. These towns, though at first largely foreign in race, became integral members of the community, able to aid and to advise the prince and to attain political importance. The peasants, with the rise of the gentry, lost in social standing but gained economically by the rights granted under Magdeburg law in the reign of Casimir III—a situation that only slowly worsened as serfdom grew up a century later. From the small body of educated men who made the court of Bolesław III superior to that of the early kings (with the famous Otto, later bishop of Bamberg, and the anonymous scholar who wrote the first history of Poland), through the spread of western social and moral ideas (at first chiefly by the Cistercians) to the writing of a real historical work by Wincenty Kadłubek (d. 1223), the great progress of learning in the Polish community can be followed, only temporarily interrupted by the Mongol invasions. The great problem of the Poles was to seek and assimilate western institutions and ideas while retaining and cherishing their own native civilization. They were forced to learn mainly from the Germans. But the political exploitation of this position by the latter led to the rise of strong anti-German feeling and to the practice of seeking models in Italy, France or the Low Countries in preference to Germany. The union of Poland and Lithuania was a mortal blow to the position of the Teutonic Order, the greatest German power on the Polish border.

THE JAGIELLON DYNASTY

Jadwiga and Władysław II Jagiello.—The magnates of Cracow, Casimir III's pupils and successors, were able to instruct the girl queen and the pagan king in the arts of government. One of the first acts of the new king was to receive Christianity for himself and his people. The Lithuanians, unlike the Ruthenian members of their grand duchy who were Orthodox, joined the western Catholic Church. So the Poles gained by peaceful agreement what the German Knights had sought by violence during a century and failed to win the conversion of the last great body of pagans in Europe. The very reason for the existence of the order had gone, and it would have to struggle to preserve its territories which included Pomorze with Danzig (Gdańsk) and the whole of Prussia. But the settlement was delayed for some time, partly because of Jadwiga's religious scruples against fighting a crusading body, and partly because Władysław Jagiello had to solve the difficult problem of Lithuania, where he had a rival in his cousin Vytautas (Witold). The order exploited this situation so adroitly that the king was forced to recognize Vytautas as grand duke of Lithuania. This arrangement was successful for a time, and in 1409 the aggression of the order provoked the two cousins to join their forces against their common enemy. Advancing into Prussia they completely defeated the Knights in the great battle of Grunwald (Tannenberg) in 1410. Unfortunately, though the victory was followed by the union of Horodlo (1413), which established in Lithuania institutions based on those of Poland, the two cousins did not always agree, and Poland was exposed in the south to the hostility of Sigismund of Bohemia, who had succeeded to the possessions of Louis of Hungary in 1387 and to the German kingdom in 1410. Jagiello lost his wife Jadwiga in 1398 and remained without male issue by his next two wives; but his fourth, whom he married in 1422, the Lithuanian princess Sophia, Holczanska, gave him what Poland needed, two sons.

Throughout his long reign he continued to collaborate amicably with the Polish leaders or, occasionally, to oppose them, knowing well that the union with Lithuania depended on his own person. He suffered great anxiety from the ambitions of Vytautas, who was a great warrior and statesman and planned to conquer the Tatars and to annex Moscow. Beloved by the Lithuanian people, Vytautas died in 1430. Władysław Jagiello died in 1434, after a reign of 48 years, at a great age. He was, like most of his family, a prudent, tolerant and tenacious ruler, and he founded a dynasty that was to be one of the greatest in Europe.

Władysław III, 1434-44.—Jagiello was succeeded by his ten-year-old son Władysław III, the chief position in the realm being held by the most eminent of the Cracow magnates, Zbigniew Oleśnicki, bishop of Cracow and one of the previous king's chief advisers, who became a cardinal. Oleśnicki had to deal with a number of urgent problems: the spread of Hussitism among the gentry, the threat to European civilization from the Turks on the Danube, the possibility of the recovery of Silesia from the Czechs and of Pomorze from the Teutonic Order, and the dangerous rise of rebellion in Lithuania among the Orthodox Ruthenians. A highly cultured scholar, a great orator and diplomatist, he played a leading part in the council of Basel. The Lithuanian rebels, though supported by the master of Livonia (the Knights of the Sword had been amalgamated with the Teutonic Order in 1237), were decisively defeated in 1435 near Wilkomierz (Vilkomir, Ukmergė). A churchman, Oleśnicki was, like Queen Jadwiga, prepared to conciliate the Teutonic Order and to concentrate the national forces against the heretical Czechs (so as to recover Silesia) and against the Turk in the south. He failed in the first project, and his great crusade, which involved securing the throne of Hungary for Władysław III (who thus became Ulászló I of Hungary), was brought to a disastrous end by the defeat at Varna (1444), where Władysław was killed and his supporter John Hunyadi routed. Until his death was certain, Poland remained without a ruler for three years (1444-47), when Władysław II Jagiello's second son, Casimir, who had made himself popular in Lithuania, ascended the Polish throne. (A B Bo)

Casimir IV, 1447-92.—The difficulties which confronted Casimir were great. He recognized not only the vital necessity of the maintenance of the union between the two states but also the fact that the chief source of danger to the union lay in Lithuania. For political reasons, during the earlier years of his reign, Casimir was obliged to reside for the most part in Lithuania, and his interest in the grand duchy was always resented in Poland, where, to the very end of his reign, he was regarded with suspicion. In particular, he could never rely on adequate Polish support in the struggle, which he inherited from his predecessors, with the Teutonic Order.

The struggle assumed a new form in 1454, when Casimir accepted the suzerainty offered to him by the Prussian league, which had repudiated the authority of the order and needed a protector. The acquisition of the Prussian lands was vital to the existence of Poland. It meant the command of the principal rivers of Poland, the Vistula and the Niemen, and the acquisition of a seaboard with its corollaries of sea power and commerce. Yet, except in the border province of Great Poland, which was interested commercially, the king received little support, military or financial, and it was only with his victory at Puck (Sept. 17, 1462) that he obtained any decisive success against the order. The war was ended in 1466 by the second treaty of Toruń (Oct. 14), by which Poland recovered the provinces of Pomorze, Chełmno and Michalów, with the bishopric of Warmia (Ermland), numerous cities and fortresses, including Marienburg, Elbing, Danzig and Toruń. The territory of the Knights was now reduced to Prussia proper, embracing, roughly speaking, the district between the Baltic, the lower Vistula and the lower Niemen, with Königsberg as its capital. For this territory each grand master within nine months of his election was in future to render homage to the Polish king, who undertook not to make war or to engage in any important enterprise without Prussian consent. Prussia had now become a Polish province, and Poland had acquired a seaboard.

The whole foreign policy of Casimir IV was influenced by the

Prussian question. At the beginning of the war both the empire and the papacy were against him. He therefore allied himself with George of Podebrad, whom the Hussites had placed on the throne of Bohemia. On the death of George (1471), Casimir's eldest son, Vladislav (i.e., in Polish, Wladyslaw), was elected king of Bohemia by the Utraquist party, despite the determined opposition of Matthias Corvinus (Matthias I Hunyadi), the king of Hungary, who thenceforward deliberately set about traversing all the plans of Casimir. He encouraged the Teutonic Order to rebel against Poland, he entertained at his court anti-Polish embassies from Moscow, he encouraged the Tatars to ravage Lithuania, he thwarted Casimir's policy in Moldavia. His death in 1490 came, therefore, as a distinct relief to Poland, and all danger from the side of Hungary was removed when Vladislav, already king of Bohemia, was elected king of Hungary also.

It was in the reign of Casimir IV that Poland first came into direct collision with the Turks. The Jagellons, as a rule, prudently avoided committing themselves to any political system which might irritate the still distant but much-dreaded Turk, but when their dominions extended so far southward as to embrace Moldavia the observance of a strict neutrality became exceedingly difficult. Poland had established a sort of suzerainty over Moldavia as early as the end of the 14th century, but at best it was a loose and vague overlordship which the hospodars repudiated whenever they were strong enough to do so. The Turks themselves were too much occupied elsewhere to pay much attention to the Danubian principalities till the middle of the 15th century, and it was not till 1484 that they became inconvenient neighbours to Poland. In that year a Turkish fleet captured the strongholds of Kilis and Akkerman, commanding, respectively, the mouths of the Danube and Dniester. This aggression seriously threatened the trade of Poland, and induced Casimir IV to accede to a general league against the Porte. In 1485, after driving the Turks out of Moldavia, the Polish king, at the head of 20,000 men, proceeded to Kolomyja on the Pruth, where Bayezid II, then embarrassed by an Egyptian war, offered peace, but as no agreement concerning the captured fortresses could be arrived at, hostilities were suspended by a truce. During the remainder of Casimir's reign the Turks gave no trouble.

John Albert and Alexander.—The death of Casimir was followed by the temporary separation of Poland and Lithuania and by a strong anarcho-catholic reaction in Poland itself. Casimir's third son, John Albert, was elected king of Poland, and his fourth son, Alexander, became grand duke of Lithuania. On the death of John Albert in 1501, Alexander succeeded him as king, and the union of Poland and Lithuania assumed a more definite character, the senate of each country agreeing that in future the king of Poland should always be grand duke of Lithuania. The acquisition of Lithuania was essentially the result of a new danger which had arisen in the east. Till the accession of Ivan III in 1462 Moscow had been a negligible factor in Polish politics. During the earlier part of the 15th century the Lithuanian princes had successfully contested Muscovite influence even in Pskov and Great Novgorod. Many Russian historians even maintain that, but for the fact that he had simultaneously to cope with the Teutonic Order and the Tatars, Vytautas would have extinguished struggling Moscow altogether. But since the death of Vytautas (1430) the military efficiency of Lithuania had sensibly declined, and the natural attraction of the Orthodox Greek element in Lithuania toward Moscow threatened the integrity of the grand duchy. During the reign of Alexander, who was too poor to maintain any adequate standing army in Lithuania, the Muscovites and Tatars ravaged the whole country at will and were prevented from conquering it altogether only by their inability to capture the chief fortresses. In Poland, meanwhile, Alexander had practically surrendered his authority to an incapable anarchy, while the dependent states of Prussia in the north and Moldavia in the south made strenuous efforts to break away.

Sigismund I, 1506-48.—Fortunately for the integrity of the Polish state, the premature death of Alexander in 1506 brought upon the throne his capable brother Sigismund, the fifth son of Casimir IV. Eminently practical, Sigismund I recognized that

the first need of Poland was a standing army, that Poland, in order to hold its own, must in future follow the example of the west and wage its warfare with trained mercenaries. The great financial and military liberties of the Polish gentry for long prevented both the organization of an adequate national army and the development of a modern fiscal system. Much of the internal history of Sigismund's reign turns on the various proposals made toward these ends, most of which were defeated or mutilated by the aristocratic opposition in the *sejm*. The long, open frontiers of the Polish kingdom invited invasion, and the misfortunes which fell on Poland at a later time largely resulted from the failure of the defensive measures proposed by Sigismund and his advisers. Throughout his reign, the king was hampered by lack of resources. In 1525 he was compelled to grant autonomy to the province of Prussia instead of annexing it, he was unable to succour his unfortunate nephew, Louis II of Hungary, against the Turkish peril, or to prevent the occupation of one Lithuanian province after the other by the Muscovites.

To this period belong the first attempts to provide for the defense of the *dnieks pola*, or "savage steppe," as the vast plain was called which extended from Kiev to the Black sea. In the reign of Alexander, the fugitive serfs who had escaped into this wilderness (they were subsequently known as Kazaks, or Cossacks, a Tatar word meaning "freebooters") had been formed into companies (c. 1504) and placed at the disposal of the frontier *starostas*, or lord marchers, of Kaniov, Kameniec Podolski (Kamenets-Podolsk), Cherkask on the Don and other places. But these measures proved inadequate, and in 1533 the lord marcher Ostafi Daszkiewicz, the hero of Kaniov, which he had successfully defended against a countless host of Turks and Tatars, was consulted by the diet as to the best way of defending the Ukraine permanently against such incursions. The veteran expert advised the populating and fortifying of the islands of the Dnieper. But nothing was done officially. The selfish prudence of Bona Sforza, Sigismund's second wife, did more for the national defense than the Polish state could do. To defend her immense possessions in Volhynia and Podolia, she converted the castles of Bar and Krzemieniec into first-class fortresses and placed the former in the hands of her Silesian steward, who acquitted himself so manfully of his charge that "the Tatars fell away from the frontier all the days of Pan Petrycz," and a large population settled securely beneath the walls of Bar, henceforth known as "the bastion of Podolia."

The most important political event in eastern Europe during the reign of Sigismund was the collapse of the ancient Hungarian monarchy at Mohacs in 1526. After the death of King Louis in the battle, the emperor Ferdinand and John Zapolya, voivode of Transylvania, competed for the vacant crown, and both were elected almost simultaneously. In Poland Zapolya's was the popular cause, and he also found powerful support in the influential and highly gifted Laski family, represented by the Polish chancellor and his nephews Jan and Hieronymus. Sigismund, on the other hand, favoured Ferdinand of Austria. He argued that the best way to keep the Turk from Poland was for Austria to incorporate Hungary, in which case the Austrian dominion would be a strong and permanent barrier against a Moslem invasion of Europe. History more than justified him, and the long duel which ensued between Ferdinand and Zapolya (see *HUNGARY: History*) enabled the Polish monarch to maintain to the end a cautious but observant neutrality. More than once, indeed, Sigismund was seriously compromised by the diplomatic vagaries of Hieronymus Laski, who entered the service of Zapolya (since 1520 the protégé of the sultan) and greatly alarmed both the emperor and the pope by his disturbing philo-Turk proclivities. As a result of Laski's intrigues, the new hospodar of Moldavia, Petrylo, after doing homage to the Porte, intervened in the struggle as the foe of both Ferdinand and Sigismund, and besieged the grand hetman of the crown, Jan Tarnowski, in Obertyn, where, however, the Moldavians (Aug. 22, 1531) sustained a crushing defeat, and Petrylo was slain. Nevertheless, so anxious was Sigismund to avoid a collision with the Turks that he forbade Tarnowski to cross the Moldavian frontier and sent a letter of explanation to Constantinople. On the death of John Zapolya, the Austro-Polish

alliance was still further cemented by the marriage of Sigismund's son and heir, Sigismund Augustus, with the archduchess Elizabeth. In the reign of Sigismund was effected the incorporation of the duchy of Mazovia with the Polish crown, after an independent existence of 500 years. In 1526 the male line of the ancient dynasty became extinct, and on Aug. 26 Sigismund received the homage of the Mazovians at Warsaw, the capital of the duchy and before long of the whole kingdom.

(R N B, F M S, X)

Sigismund II Augustus, 1548-72.—Already in the 15th century the University of Cracow had brought forth humanist scholars of European repute and begun to attract distinguished lecturers and numerous students from abroad. Thanks to Sigismund I's marriage to a Sforza of Milan, the royal court at Cracow became the home of the highest Renaissance art of Italy, and the royal castle on Wawel hill at Cracow, rebuilt by Italian architects and their Polish disciples, became one of the finest monuments of Renaissance style north of the Alps. Under Sigismund II the third great spiritual factor of the age, next to humanist scholarship and Renaissance art—the doctrine of the Reformation—entered potently into Poland's intellectual life, uniting with Italian culture on the common ground of literature and helping to produce the first great age of Polish poetry and prose. There followed the clash between the New Learning and the strong tradition of Poland's chivalrous Catholicism, the difficulties with the Scandinavian powers and the rising empire of the Moscow tsars, the dilemma produced between the evolution of the Polish parliamentary system and the Renaissance tendency toward the strengthening of central government authority. Even a king of genius could be only partially successful in coping with all these tasks, and the reign of Sigismund II, in many respects one of the most brilliant in Polish annals, left the seeds of decay and failure behind it.

Reformation and Counter Reformation.—The new king having shown his temper by marrying a lady of the noble house of Radziwiłł without asking for the opinion of the senate, the reign began in a storm of demands for constitutional guarantees to secure the parliamentary "gentry democracy" against the powers of the crown and the nobility. The king resolutely allied himself with Austria abroad and with the bishops and the nobles at home, against a threatened revolt of the gentry. In doing so, he had to take the bishops' side in the issue between the Reformation and Catholic orthodoxy, and he affirmed this by an edict against heresy in 1550. But this act only opened up the long-maturing dispute about the creation of a national church after the recent example of Henry VIII of England. The king, a man of enlightened mind, the first Polish monarch who habitually used the vernacular language instead of Latin at public functions, showed in many ways a sympathetic understanding for the tendencies of the new era. The influence of the Bohemian Hussite movement of 100 years before combined with nascent modern nationalism to inspire definite programs for a Reformed Polish state church with Polish ritual, independent of Rome, and with a priesthood subject to government authority. The large Greek Orthodox element among the citizens of the eastern provinces of the monarchy furnished an additional stimulus, which gave strength to such demands as that for the abolition of clerical celibacy in the Lutheran fashion. The bishops resorting to high-handed measures of repression, the *sejm* of Piotrków in 1552 voted, at the king's own suggestion, the suspension of clerical courts for a twelve-month. This was extended afterward and solemnly renewed by another *sejm* in 1555, during which masses were actually said in Polish and the communion was administered in two kinds. A religious interm of about ten years followed, during which Protestantism in Poland flourished exceedingly. Presently reformers of every shade of opinion, even those who were tolerated nowhere else, poured into Poland, which speedily became the battleground of all the sects of Europe. Soon the Protestants became numerous enough to form ecclesiastical districts of their own. The first Calvinist synod in Poland was held at Pinczów in 1550. The Bohemian Brethren, expelled from their own country, ultimately coalesced with the Calvinists at the synod of Kozminek (Aug. 1555). In the *sejm* itself the Protes-

tants were absolutely supreme and invariably elected a Calvinist to be their marshal. The king, however, perceiving a danger to the constitution in the violence of the gentry, not only supported the bishops but quashed reiterated demands for a national synod. The *sejm* of 1558-59 indicates the high-water mark of Polish Protestantism. From this time forward it began to subside, gradually but unmistakably, chiefly because of the division among the reformers themselves. From the chaos of creeds resulted a chaos of ideas on all imaginable subjects, politics included. The anti-Trinitarian heresy proved to be the chief dissolvent, and from 1560 onward the relations between the Lutherans and the Calvinists were fratricidal rather than fraternal, Jan Łaski (*q v*) vainly strove to unite all Polish Protestants round the Helvetic standard, and a federation of all Poles of the Reformed faith—the "concord of Sandomez," 1570, predominantly Calvinist in character—met resolute Lutheran opposition and led to nothing.

While the strong individualism of the Polish national character thus thwarted all endeavors at Protestant consolidation, the wars against Orthodox Moscow effectively united Poles round their old Catholic banners, and the vigorous Protestant propaganda conducted from Königsberg by Poland's vassal Albert, duke of East Prussia, appeared to the bulk of the nation under the guise of a German menace. These political factors told in favour of Catholicism, so did presently the wiser policy of Rome. Pope Pius IV, unlike his predecessor, adopted a conciliatory attitude toward the Polish crown in the matter of disputed appointments of bishops. The new bishops were holy and learned men, very unlike the creations of Queen Bona Sforza, and capable papal nuncios reorganized the scattered and faint-hearted Catholic forces in the land. From one of the ablest of them, Giovanni Commendone, the king, at the *sejm* of 1564, accepted the book of the decrees of the Council of Trent, immediately afterward he issued decrees banishing the more extreme heretics from the country. In 1565 the Jesuits, the vanguard of the Catholic Counter Reformation, appeared in Poland.

At their best, the various forms of Protestantism had never won more than a scanty noble and intellectual elite of the nation, they had never taken root among the peasantry or the petty bourgeoisie. While the gradual effacement of Reformed creeds removed a powerfully creative intellectual and literary factor from Poland's life, the re-establishment of Catholicism restored to the country that spiritual unity which was to be the chief source of national strength in the coming struggle against the aggression both of Orthodox Russia and of Lutheran Germany.

The Incorporation of Livonia.—Access to the Baltic had been a vital question since the dawn of the Polish state in the 10th and 11th centuries. Poland's expansion eastward, which began definitely in the 14th century through the acquisition of Halicz by Casimir the Great and was continued in the 15th through the dynastic union with Lithuania, made an extension of its foothold on the Baltic shore imperative. At the same time, the knights of the Teutonic Order (*q v*) had threatened to cut Poland off from access to the sea altogether. They had been beaten down by the earlier Jagellons, and access to the sea was secured by way of Danzig. But in the 16th century the foe began to regain strength in the secular and Protestant duchy of East Prussia, formally owing allegiance to Poland. Sigismund II was naturally attracted by an opportunity to outflank this foe and to gain a separate outlet to the sea.

In the middle of the 16th century the Order of the Knights of the Sword (the Livonian Order), whose territory embraced Estonia, Livonia, Courland, Semigallia and the islands of Dago and Oesel, was tottering. All the Baltic powers were more or less interested in the apportionment of this vast tract of land, whose geographical position made it not only the chief commercial link between east and west but also the emporium whence the English, Dutch, Swedes, Danes and Germans obtained their grain, timber and most of the raw products of Lithuania and Moscow. Poland and Moscow as the nearest neighbours of this moribund state, which had so long excluded them from the sea, were vitally concerned in its fate. After an anarchic period of suspense, lasting from 1546 to 1561, during which Sweden secured Estonia while

Ivan the Terrible fearfully ravaged Livonia, Sigismund II, to whom both the master of Livonia and the archbishop of Riga had appealed more than once for protection, at length intervened decisively. At his camp before Riga in 1561 the last master, who had long been at the head of the Polish party in Livonia and had embraced Protestantism, and the archbishop of Riga gladly placed themselves beneath Sigismund's protection, and by a subsequent convention signed at Wilno (Nov. 28, 1561) Livonia was incorporated with Lithuania in much the same way as Prussia had been incorporated with Poland 36 years previously, that is to say, as a new Protestant duchy and as a fief of the Polish crown, with local autonomy and freedom of worship.

Union with Lithuania, 1569.—The danger to Lithuania, revealed in the Baltic wars with Ivan the Terrible, as well as the apathy shown in these matters by the Polish *sejm*, must have convinced so statesmanlike a prince as Sigismund II of the necessity of preventing any possibility of cleavage in the future between the two halves of his dominions. A personal union under one monarch had proved inadequate. A further step must be taken—the two independent countries must be transformed into a single state. The principal obstacle was the opposition of the Lithuanian magnates, who feared to lose their dominance in the grand duchy if they were merged in the *szlachta* (gentry) of the kingdom. When things came to a deadlock in 1564, the king tactfully intervened and voluntarily relinquished his hereditary title to Lithuania, thus placing the two countries on a constitutional equality and preparing the way for fresh negotiations. The death in 1565 of Nicholas Radziwill the Black, the chief opponent of the union, still further weakened the Lithuanians, but the negotiations, reopened at the *sejm* of Lublin in 1569, at first also led only to rupture. Then Sigismund executed his master stroke. Knowing the sensitiveness of the Lithuanians regarding Volhynia and Podolia, he suddenly, of his own authority, formally incorporated both these provinces with the kingdom of Poland, whereupon, amid great enthusiasm, the Volhynian and Podolian deputies took their places on the same benches as their Polish brethren. The hands of the Lithuanians were forced. Even a complete union on equal terms was better than mutilated independence. Accordingly they returned to the *sejm* and the union was unanimously adopted on July 1, 1569. Henceforth the kingdom of Poland and the grand duchy of Lithuania were to be one inseparable and indivisible body politic, all dependencies and colonies, including Prussia and Livonia, were to belong to Poland and Lithuania in common. The retention of the old duality of dignities was the one reminiscence of the original separation, it was not abolished till 1791, four years before the final partition of Poland.

The union definitely shifted Poland's political centre of gravity eastward, it created a common interest in the Russian menace to the long and naturally defenseless eastern frontier and in the millions of Greek Orthodox people living in the eastern borderlands. Warsaw was appointed one of the meeting places of the joint *sejm*, thus preparing the transfer of the capital from Cracow to Warsaw. The union was the last great historical act of the Jagiellon dynasty, it put the coping stone to the structure of a monarchy which, with growing consolidation, seemed to bear in it the promise of empire.

Political Development.—Simultaneously with the transformation into a great power of the petty principalities which composed ancient Poland, another and equally momentous political transformation was proceeding within the country itself.

The origin of the Polish constitution is to be sought in the *sejms* or councils of the Polish princes during the period of division. The privileges conferred upon the magnates of whom these councils were composed, especially upon the magnates of Little Poland (who brought the Jagiellons to the throne, directed their policy and grew rich upon their liberality), angered the less favoured *szlachta*, who, toward the end of the 14th century, combined for mutual defense in their *sejmiks* or local diets.

The first *sejm* to legislate for all Poland was that of Piotrków (1493), summoned by John Albert to grant him subsidies, but the mandates of its deputies were limited to 12 months, and its decrees were to have force for only three years. John Albert's

second *sejm* (1496), after granting subsidies the burden of which fell entirely on the towns and peasantry, passed a series of statutes benefiting the nobility at the expense of the other classes. These were followed by others of the same kind under his successor, Alexander, which, by facilitating import and crippling export trade in the interests of the gentry, enfeebled and degraded the middle class and thereby seriously disturbed the social equilibrium of the state. Nevertheless, so long as the Jagiellon dynasty lasted, the political rights of the cities were jealously protected by the crown against the usurpations of the nobility. The burghers of Cracow, the most enlightened economists in the kingdom, supplied Sigismund I with his most capable counsellors during the first 20 years of his reign (1506-26). Sigismund's predecessor, Alexander, had been compelled to accept the statute *Nihil novi* (1505), which gave the *sejm* and the senate an equal voice with the crown in all executive matters. Under Sigismund I some of the royal prerogatives were recovered, but in his later years the influence of the gentry returned and the *sejm* succeeded in controlling all the great offices of state. The Polish parliamentary system, vesting supreme powers in the two houses of the *sejm*, was an established fact. Sigismund II knew that only a strengthening of the central authority could save the state. But his endeavours to manoeuvre his way between the two rival powers of the magnates and the lesser gentry were, on the whole, unsuccessful. A patriotic party of gentry democrats arose, veiling its program of democratic reforms under the conservative watchword of the "execution of the laws" and dealing further legislative blows at the trade of the towns and the social status of the middle class. The king, who at first sided with the great nobles against the "executionists," afterward allied himself with the latter to curtail the power of the magnates by a repeal of former royal grants of land and by the imposition of a tax on all tenants of crown lands for the maintenance of the army (1562-63). Beneficial as this was, it was obtained only at the price of further dependence of the crown on the *szlachta*.

THE ELECTIVE KINGS

The childless Sigismund II Augustus died suddenly in 1572. Fortunately for Poland, the political horizon was unclouded. Domestic affairs, however, were in an almost anarchical condition. The union of Lublin, barely three years old, was anything but consolidated, and in Lithuania it continued to be extremely unpopular. Worst of all, there was no recognized authority in the land to curb its jarring centrifugal political elements. Civil war was happily averted at the last moment, and a national convention assembled at Warsaw in April 1573 for the purpose of electing a new king. Five candidates for the throne were already in the field. Lithuania favoured Ivan IV. In Poland the bishops and most of the Catholic magnates were for an Austrian archduke, while the strongly anti-German *szlachta* were inclined to accept almost any candidate but a German. It was easy, therefore, for the adroit and energetic French ambassador to procure the election of the French candidate, Henry of Valois, duke of Anjou. Well provided with funds, he speedily bought over many of the leading magnates. Having been one of the instigators of the St. Bartholomew massacre, he was looked at askance by the Protestants, the religious difficulty in Poland, however, had meanwhile been adjusted to the satisfaction of all parties by the compact of Warsaw (Jan. 28, 1573), which granted absolute religious liberty to all non-Catholic denominations without exception—a far more liberal measure than the Germans had made in the religious peace of Augsburg 18 years before. Finally, early in April 1573 the election *sejm* assembled at Warsaw, and Henry was elected king of Poland.

Henry of Valois, 1573-74.—The election had been preceded by a *correctura iurum*, or reform of the constitution, which resulted in the famous "Henrician articles" which converted Poland from a limited monarchy into a republic with an elective chief magistrate. The king was to have no voice in the choice of his successor. He was to marry a wife selected for him by the senate. He was to be neutral in all religious matters. He was not to lead the militia across the border without the consent of the *szlachta*,

and then only for three months at a time. Should the king fail to observe any one of these articles, the nation was *ipso facto* absolved from its allegiance. Whatever its intrinsic demerits, the disastrous fruits of this reform were largely caused by the precarious geographical position of Poland, and it must be remembered to Poland's credit that it alone with England preserved the tradition of parliamentary government in the increasingly absolutist Europe of the time.

The reign of Henry of Valois lasted 13 months. The tidings of the death of his brother Charles IX determined him to exchange a thorny for what he hoped would be a flowery throne, and at midnight on June 14, 1574, he literally fled from Poland to become Henry III of France. In Nov. 1575 the senate elected the emperor Maximilian II to the throne; but the gentry democracy, at the suggestion of its new leader Jan Zamoyski (*q.v.*), chose a prince of Transylvania, Stephen Bathory, assigning him for husband to the last surviving princess of the Jagiellon dynasty, and enforced this election by arms.

Stephen Bathory, 1575-86.—The king elected by the "patriotic" party proved one of Poland's greatest kings. The glorious 11 years of his reign, too brief to be permanently effective, yet represent the high-water mark of Poland's international power, and the achievements of his genius both in foreign and domestic policy remain unsurpassed in Polish annals. (*See STEPIEN [ISTVAN] BATHORY*.)

With the insight of a born statesman he focused his energy on two vital objectives, the maintenance of Poland's access to the sea by way of Danzig, and the defense of its newly gained further seaboard in the northeast against the rising power of Moscow. Danzig, on Bathory's election, began to intrigue against him with the emperor Maximilian (until his death in Oct. 1576) and with Russia and Denmark. In spite of a deplorable lack of understanding on the part of the Polish gentry for the issue at stake, Bathory, who had throughout the able and strenuous support of his chancellor Zamoyski, conducted a campaign against Danzig both by land and sea and finally enforced its complete submission to his rule.

Before peace was made with Danzig, Ivan the Terrible had raided Livonia once more. Bathory, for the first time in the history of Polish warfare using infantry rather than cavalry and calling peasants and burghers to arms together with the gentry, achieved in the operations against Russia the greatest military triumphs of his reign. In three successive expeditions he pushed his way northeastward as far as Pskov, and the tsar was fain to obtain the pope's intervention by a promise of making Russia Catholic. As a result of Bathory's victories, Poland pushed Russia entirely away from the Baltic for a long time and regained sway over nearly the whole of Livonia.

Brilliant as these foreign successes were, the greatness of Bathory's statesmanship was even more manifest at home. He conciliated, by concessions and privileges, two of the most important minority groups, the Ukrainian Cossacks and the Jews. The Cossacks were largely runaway serfs, who had organized themselves into a sort of military republic on the vast and scantily inhabited plains of the Ukraine or "borderland," stretching from the south-east of the monarchy toward the Black sea along the river Dnieper. The Cossack community had been drawn into the Polish military system under Bathory's predecessors by registration and pay and had already been granted exemption from taxation, as well as their own jurisdiction. Bathory, who needed them for his Russian wars, confirmed and enlarged these privileges. His successors used the Cossacks against the Russians, Turks and Tatars, but soon the Cossacks themselves were to grow into a factor of trouble for Poland, not without serious errors of policy on the Polish side.

The privileges which the Jews had obtained from former kings were augmented, from Bathory's day until 1764 the Polish Jews had a parliament of their own, meeting twice a year, with powers of taxation. It was also chiefly in the interest of the Jews that Bathory restricted, by special edict, the trading rights of Scottish pedlars, of whom as many as 30,000 were abroad in Poland in his time. Among other domestic measures, Bathory reformed the Polish judicial system by the creation of a supreme court of appeal for civil cases, and he founded, in 1579, the University of

Wlino as a bulwark of western European culture in the east.

The growing imperial ambitions of the house of Habsburg had developed into a menace to Poland's international position; they now threatened to outflank and encircle Poland on the southern side. Bathory proposed to counteract them by the project of a union with Russia and a joint crusade against Turkey under the auspices of the pope. This grandiose plan would have given Poland again a firm footing on the shore of its "second sea"—the Black sea—which it had reached once before in the time of the Jagiellons. But the idea was carried with Bathory to his grave on his sudden death in 1586.

Sigismund III, 1587-1632.—The Vasa period of Polish history, which began with the election of Sigismund, son of John III of Sweden and of Sigismund I's daughter Catherine, was one of last and lost chances. The collapse of the Muscovite tsardom and the submersion of Germany by the Thirty Years' War presented Poland with an unprecedented opportunity of consolidating, once for all, its hard-won position as the dominating power between central and eastern Europe, it might even have wrested the best part of the Baltic littoral from the Scandinavian powers and pushed Russia back beyond the Volga. That this was not achieved was partly caused by the class spirit and blind selfishness of the Polish gentry. Apathetic toward vital problems of foreign policy and unwilling to make material sacrifices to the cause of national defense, they persisted in a doctrinaire defense of "republican liberty" at the very time when the need of a strong central executive was more urgent than ever.

But other grave causes of failure were not wanting. One of them consists in the very personality of the new foreign-bred king, the tenacity with which he clung to his hereditary rights to the Swedish crown involved Poland in unnecessary wars with Sweden at most inopportune times, and his bigoted devotion to the cause of Catholicism introduced a new spirit of religious fanaticism and persecution into the atmosphere of a country hitherto distinguished for toleration, while the same bigotry served Poland's interests very ill abroad. Poland's greatest statesman of the time, Jan Zamoyski, discovered in the earliest years of the reign that the king, who had married Anne, daughter of the Habsburg Charles of Styria, was willing to surrender the crown of Poland to an Austrian archduke and to return to his native Sweden in order to bring it back to the Catholic fold. Zamoyski, who had himself placed Sigismund on the throne by conquering a rival Austrian candidate, was naturally indignant, and the whole disgraceful affair of the king's secret negotiations with Austria culminated in his having to answer the charges of a special "court of inquisition" (1592)—the first time that the prestige of the crown in Poland was exposed to such an ordeal.

The Uniate Church.—It was only where the expansion of Catholicism served the interests of the Polish state that Zamoyski saw eye to eye with the king's Catholic zeal. Thus, he became instrumental in creating, at the synod of Brzesc in 1596, the Uniate Church as a halfway house for those of the republic's Greek Orthodox citizens who were willing to recognize the supremacy of Rome but desired to preserve their accustomed Eastern ritual and Slavonic liturgy. The Uniate Church served the purpose of drawing a large section of the population of the eastern border provinces out of the orbit of Moscow and into that of Polish influences, but by the antagonisms which soon began between Uniates and non-Uniates, it became in itself a source of new troubles for Poland. Besides this, the pride of Poland's Roman Catholic prelates, who looked down on the Uniate hierarchy, forced the Uniate Church into the position of a "peasant religion" and contributed to making it the social nucleus of anti-Polish Ukrainian nationalism which it henceforth remained. Even in Sigismund's time, Austria, competing with Poland for influence in the eastern Balkans, began to seduce the Ukrainian element (represented in organized form by the military community of the Cossacks) against Poland—a policy which the same Austria was to resume later in changed form and under different conditions when mistress of eastern Galicia.

Swedish, Muscovite and Turkish Wars.—The dispute over Sigismund's rights to the Swedish crown began, from the earliest years

of the reign, to drag its weary course of alternate victories and defeats. At first the areas that later became Estonia and Latvia were both the scene and the principal object of the strife, in the later stages, Gustavus Adolphus transferred the ground nearer to the heart of Poland by espousing the cause of the Calvinist elector of Brandenburg, who had come into possession of East Prussia and thus laid the foundation of a large Protestant power on the Baltic. The danger to Danzig and Poland's grain exports roused even the gentry from their apathy, but in spite of some brilliant victories by sea and land, an armistice toward the end of the reign was highly unfavourable to Poland.

Sigismund's persistent Swedish ambitions, his equally persistent Austrian sympathies, but, more than all, his absolutist leanings and chenshed plans for a drastic and arbitrary constitutional reform on foreign models and on antiparliamentary lines occasioned in 1606 an armed revolt of the Polish gentry against their king—the *rokosz* (or insurrection) of Mikolaj Zebrzydowski, who was supported by the discontented Protestants. The *rokosz* was at last suppressed in 1607, but it left as its legacy such ruinous precedents as an enforced recognition of the doctrine of the subjects' right to depose their king (*de non praestanda obedientia*) and, being undertaken in justified defense of the native parliamentary tradition against wholesale foreign innovations, had the harmful effect of blocking the way toward any and every reform of the parliamentary system.

Soon after the constitutional cataclysm of the *rokosz*, Poland became embroiled in prolonged wars with Moscow. The motive was partly a vague conception of a Polish-Russian union as opposed to the king's Austrian propensities, but partly also the very real desire of some border magnates for more and more land east of the Dnieper. An occasion was furnished by the extinction of the dynasty of Rurik in Russia and the subsequent struggle for the throne, particularly the emergence of one candidate—the ill-fated Pseudo-Demetrius (*see DEMETRIUS, PSEUDO*)—whom certain Polish nobles and finally also the king supported. The appearance of a second Pseudo-Demetrius after the fall of the first prolonged the strife. Throughout the campaigns against Moscow the king found himself at variance with some leading Polish statesmen and soldiers of the time, such as Zamoycki and, later, Stanislaw Zolkiewski, he thought of the problem only in terms of conquest, of the establishment of Catholicism in Russia and of strong monarchical rule over the united kingdoms, while Zolkiewski, even at the height of military successes against Russia, had a union like that of Poland with Lithuania in his mind and advocated tolerance of Russia's creed and social order. The Poles once actually held the Kremlin of Moscow for a time (1610) and once again laid siege to it (1617), Sigismund's son Wladyslaw was elected tsar, and his opponent did homage to Sigismund as a prisoner. But a national insurrection in Russia and the establishment of the Romanoff dynasty checked the Polish advance, and only certain territorial gains (including Smolensk), as well as a good deal of influence of Polish customs and institutions on the Russian nobility, were definite results of the struggle in Sigismund's time. It was to be continued under his successors.

The wars with Moscow temporarily ended in an armistice at the very moment (1618) when the Thirty Years' War broke out in central Europe. In this Poland remained officially neutral, but Sigismund's favourable attitude toward the Habsburgs entangled Poland in renewed and long wars with Turkey, which the later Jagellons and their first successors had managed to avoid. A definite success was attained against the Turks at Hotin (1621), a year after Zolkiewski's heroic death at Cecora. But the Swedish trouble began anew in the same year, and Sigismund's long and unlucky reign ended 11 years later amid turmoil abroad and at home, setbacks to Polish power on all sides without and seriously increased constitutional disorder within.

Wladyslaw IV, 1632-48.—Sigismund's son, born in Poland and brought up as a Pole, enjoyed a popularity which had never been his father's lot. As crown prince, he had been successful in military operations against Moscow and Turkey; on his ascension to the throne he ingratiated himself with the gentry by some new concessions, including even exemption from income tax. The

"wisest of the Polish Vasas," as he has been called, intended to create a basis of public favour and confidence for the constitutional reforms which he planned.

But the international difficulties inherited from his father diverted his energies largely into channels of foreign policy. The very first years of his reign are marked by new victories over Russia and the Turk and also by a new and much more advantageous truce with Sweden. He was less fortunate in a new conflict with Danzig, and with its supporter Denmark, over the tolls he intended to impose on the trade of the Baltic ports, no interest in these matters was to be awakened in the gentry, and the most powerful magnates—those of the eastern border—thought more of expansion into the fertile Ukrainian regions than of sea power. Accordingly, the Polish navy, which had begun to develop in a promising manner under Sigismund III, was allowed to fall into permanent decay, and Wladyslaw's plans for foreign action on a large scale were unrealized. He wavered in his diplomacy between Austrian and French influences, represented by his two successive queens, his tolerant and friendly attitude toward the Orthodox east caused serious trouble with the Vatican; and his project of a great crusade against the Turks, although encouraged by the Venetian republic and acclaimed by the south Slav nations, in the end came to nothing.

The Cossack Revolt.—The chief obstacle which prevented Wladyslaw's Turkish plans from maturing was the impossibility of winning the help of the decisive factor, the Ukrainian Cossacks, who had become too numerous and powerful to be willing instruments of Polish policy. Catholic intolerance toward this Orthodox population, in the time of Sigismund III, had combined with the proud and highbanded behaviour of Polish landowners to produce in the Cossacks a spirit of religious, racial and social enmity against the Polish element, the Polish parliament had not kept the financial terms of its compacts with the Cossacks, repressions inspired by the border magnates had infuriated them. Already in the earlier years of Wladyslaw's reign terrible Cossack revolts had flared up and been unwisely punished by the abolition of ancient privileges. Now, instead of letting themselves be made the tools of Wladyslaw's anti-Turkish plans, the Cossacks made common cause with the Tatars of the Crimea, who were the most immediate objective of the king's crusading plans; and the reign ended amid a wave of Cossack insurrection, engineered by the sultan, assisted by Tatar hordes and led by Bogdan Chmielnicki (*qv*), a country gentleman personally wronged by a Polish official, now the rising hero of Ukrainianism. It was only the resistance of the Polish burghers of Lwow that stemmed the Cossack and Tatar tide from flooding the inner provinces of Poland, the same patriotic town was to arrest two other invasions—a Russian and a Transylvanian one—in the next few years. But the defense of Lwow meant only a respite, and on Wladyslaw's death his brother and successor, the last of the Polish Vasas, found himself faced by a powerful renewal of Chmielnicki's attack on central Poland.

John Casimir, 1648-68.—John Casimir, summoned to the throne from France, where he had lived as a priest and become a cardinal, was obliged to begin his reign by negotiating with his rebel subject Chmielnicki. But Chmielnicki's conditions of peace were so extravagant that the negotiations came to nothing. It was only after a second invasion of Poland, in 1649, by a host of Cossacks and Tatars, that the compact of Zborow was concluded, by which Chmielnicki was officially recognized as chief (hetman) of the Cossack community. A general amnesty was also granted, and it was agreed that all official dignities in the Orthodox palatinates of Lithuania should henceforth be held solely by the Orthodox gentry. For the next 18 months Chmielnicki ruled the Ukraine like a sovereign prince. He made Czehryn, his native place, the Cossack capital, subdivided the country into 16 provinces and entered into direct relations with foreign powers. The Orthodox patriarchs of Alexandria and Constantinople were his friends and protectors. His attempt to carve a principality for his son out of Moldavia led to the outbreak of a third war between suzerain and subject in Feb. 1651. But fortune, so long Bogdan's friend, now deserted him, and at Beresteczko (1651) the

Cossack chieftain was utterly routed by John Casimir. All hope of an independent Cossackdom was now at an end, yet it was not Poland but Moscow which reaped the fruits of this great victory.

Chmielnicki, by suddenly laying bare the nakedness of the Polish republic, had opened the eyes of Moscow to the fact that its ancient enemy was no longer formidable. Three years after his defeat at Beresteczko, Chmielnicki, abandoned by his Tatar allies and finding himself unable to cope with the Poles single-

handed, very reluctantly transferred his allegiance to the tsar Aleksei Mikhailovich, whose armies in the same year invaded Poland. The war thus begun is known in Russian history as the Thirteen Years' War and far exceeded even the Thirty Years' War in grossness and brutality.

In the summer of 1655, while Poland was still reeling beneath the shock of the Muscovite invasion, Charles X of Sweden, on the flimsiest of pretexts, forced a war to gratify his greed of martial glory, and before the year was out his forces had occupied the capital, the coronation city and the best half of the land. King John Casimir, betrayed and abandoned by his own subjects, fled to Silesia. Profiting by the cataclysm which, for the moment, had swept the Polish state out of existence, the Muscovites quickly appropriated nearly everything which was not already occupied by the Swedes. At this crisis Poland owed its salvation to two events—the formation of a general league against Sweden, brought about by the apprehensive court of Vienna, and a popular outburst of religious enthusiasm on the part of the Polish people. The first of these events, to be dated from the alliance between the emperor Leopold I and John Casimir (1657), led to a truce with the tsar and the welcome diversion of all the Muscovite forces against Swedish Livonia. The second event, which began with the heroic and successful defense of the monastery of Czestochowa by Prior Augustyn Kordecki against the Swedes, resulted in the return of the king from exile, the formation of a national army and the recovery of almost all the lost provinces from the Swedes, who were driven back headlong to the sea, where with difficulty they held their own. On the sudden death of Charles X, Poland seized the opportunity of adjusting all its outstanding differences with Sweden. By the peace of Oliwa (Oliva) (1660), made under French mediation, John Casimir ceded Livonia and renounced all claim to the Swedish crown. The war with Moscow was then prosecuted with renewed energy and extraordinary success. In 1664 a peace congress was opened, and the prospects of Poland

seemed most brilliant; but at the very moment when it needed all its armed strength to sustain its diplomacy, the rebellion of Prince Jerzy Lubomirski evoked the country in a dangerous civil war, compelled it to reopen negotiations with the Muscovites and practically to accept the Muscovite terms. By the truce of Andruszowo (1667) Poland received back from Moscow Vitebsk, Polotsk and Polish Livonia, but ceded in perpetuity Smolensk, Severna, Chernigov and the whole of the eastern bank of the Dnieper. The Cossacks of the Dnieper were henceforth to be divided between the dominion of the tsar and the king of Poland. Kiev, the religious metropolis of southwestern Russia, was to remain in the hands of Moscow for two years.

The "truce" of Andruszowo proved to be one of the most permanent paces in history, and Kiev, though pledged for only two years, was never again to be recovered. Henceforth the political influence of Russia over Poland was steadily to increase, without any struggle at all, although influences of Polish culture and manners, exercised chiefly through the academy of Kiev, still continued to permeate Russia until the advent of Peter the Great.

The "Liberum Veto" in the 17th Century.—Poland had, in fact, emerged from the cataclysm of 1648-67 a moribund state, though its not unskilful diplomacy had enabled it for a time to save appearances. Its territorial losses, though considerable, were, in the circumstances, not excessive, and it was still a power in the opinion of Europe. But a fatal change had come over the country during the age of the Vasas. The period synchronized with and was partly determined by the new European system of dynastic diplomatic competition and the unscrupulous employment of unlimited secret service funds. This system, which dates from Richelieu and culminated in the reign of Louis XIV, was based on the rivalry of the houses of Bourbon and Habsburg, and very soon nearly all the monarchs of the continent and their ministers were in the pay of one or other of the antagonists. Poland was no exception to the general rule. To do them justice, the *szlachta* at first not only were free from the taint of official corruption but endeavoured to fight against it. But they themselves unconsciously played into the hands of the enemies of their country by making the so-called *liberum veto* an integral part of the Polish constitution. The *liberum veto* was based on the assumption of the absolute political equality of every Polish gentleman, with the corollary that every measure introduced into the Polish *sejm* must be adopted unanimously. Consequently, if any single deputy believed that a measure already approved of by the rest of the house might be injurious to his constituency, he had the right to exclaim "*Nix postulamus*," "I disapprove," the measure in question falling at once to the ground. Subsequently this vicious principle was extended still further. A deputy, by interposing his individual veto, could at any time dissolve the *sejm*, and all measures previously passed had to be resubmitted to the consideration of the following *sejm*. Before the end of the 17th century the *liberum veto* was used so recklessly that all business was frequently brought to a standstill. Later it became the chief instrument of foreign ambassadors for dissolving inconvenient sessions, as a deputy could always be bribed to exercise his veto.

Michael Wisniowiecki, 1669-74.—With the election of Michael Wisniowiecki in 1669 a new era began. A native Pole, he was freely elected by the unanimous vote of his countrymen; but he was chiefly chosen for the merit of his father, a great border magnate who had victoriously kept down the Cossacks, and he proved to be a passive tool in the hands of the Habsburgs. In view of this the French party rallied round John Sobieski, a military commander of rising fame. The dissensions between the two camps cost Poland a new defeat at the hands of the united Turks and Cossacks. Sealed by a shameful treaty of Buczacz (1672), this defeat was only wiped out by a brilliant victory of Sobieski's at Hotin, which also, after King Michael's early death, carried him to the throne against an Austrian candidate.

John III Sobieski, 1674-96.—Connected with France by marriage and by political sympathies, Sobieski, although he had had a lifetime of constant wars against the Turks behind him, stood at first, in accordance with French policy, for peaceful relations with Turkey and directed his eyes toward the Baltic, attempting

with French help to check the rising Hohenzollern power in that quarter. But his secret dealings with France turned his own subjects against him, while continuous Turkish invasions forced him into war, until an attack of unprecedented magnitude, aimed at the very heart of Europe, called forth that unprecedented outburst of Polish heroism—the gallant rescue of Vienna in 1683. That great act was the last noble reflex of the great crusading impulse of the middle ages, it was a unique service, rendered in the old chivalrous spirit by one nation to another in an age of Machiavellian diplomacy and growing national selfishness. It won Poland offers of friendship from all the great powers. But its positive gains for Poland proved little, cessions of territory to Moscow did not buy any active support in further campaigns against Turkey, nor did the delivered Austria assist Poland in its endeavour to re-establish the Rumanian outpost against the Turk.

Augustus II, 1697–1733.—On the death of John III no fewer than 18 candidates for the vacant Polish throne presented themselves. The successful competitor was Frederick Augustus I, elector of Saxony, who cheerfully renounced Lutheranism for the coveted crown and won the day because he happened to arrive last of all, with fresh funds, when the agents of his rivals had spent all their money. He was crowned, as Augustus II, in 1697, and his first act was to expel from the country his French rival, François Louis de Bourbon, prince de Conti, whose defeat was also partly caused by the growing Russian influence, which, from the accession of Peter the Great (1700), became a permanent factor in Polish domestic politics.

Good luck attended the opening years of the new reign. In 1699 the long Turkish war, which had been going on since 1683, was concluded by the peace of Karlowitz, whereby Podolia, the Ukraine and the fortress of Kamieniec Podolski were retroceded to the republic by the Ottoman Porte. But the permanent weakening of Turkey brought little good, for the power of Russia soon became a greater menace to Poland than Turkey had ever been.

Shortly after the peace of Karlowitz, Augustus was persuaded by the plausible Livonian exile Johann Reinhold Patkul to form a nefarious league with Frederick of Denmark and Peter of Russia, for the purpose of despoiling the youthful king of Sweden, Charles XII (see SWEDEN History). Thus he did as elector of Saxony, but it was the unfortunate Polish republic which paid for the hazardous speculation of its newly elected king. Throughout the Great Northern War, which wasted northern and central Europe for 20 years (1700–21), all the belligerents treated Poland as if it had no political existence. Swedes, Saxons and Russians not only lived upon the country, but plundered it systematically. The *sejm* was the humble servant of the conqueror of the moment, and the leading magnates chose their own sides without the slightest regard for the interests of their country, the Lithuanians for the most part supporting Charles XII, while the Poles divided their allegiance between Augustus and Stanislaw Leszczyński (see STANISLAUS I), whom Charles maintained upon the throne from 1704 to 1709. At the end of the war Poland was ruined materially as well as politically. Augustus offered Courland, Polish Prussia and even part of Great Poland to Frederick William I of Prussia provided that he were allowed a free hand in the disposal of the rest of his kingdom. When Prussia declined this tempting offer for fear of Russia, Augustus went a step further and actually suggested that "the four eagles" (viz., the black ones of Austria, Prussia and Russia and the white eagle of Poland proper) should divide the other Polish territories between them. He died, however, before he could give effect to this shameless design.

Augustus III, 1733–63.—On the death of Augustus II, Stanislaw Leszczyński, who had, in the meantime, become the father-in-law of Louis XV, attempted to regain his throne with the aid of a small French army corps. Some of the best men in Poland, including the Czartoryski family, were also in his favour, and he was elected king for the second time. But there were many malcontents, principally among the Lithuanians, who solicited the intervention of Russia in favour of the elector Frederick Augustus II of Saxony, son of the late king. A Russian army appeared before Warsaw and compelled a phantom *sejm* (it consisted of but

15 senators and 500 of the *szlachta*) to proclaim Augustus III Stanislaw and his partisans were besieged by the Russians in Danzig, and with its surrender their cause was lost. He retired to become duke of Lorraine and Bar, keeping the title of king of Poland but leaving Augustus III in possession of the kingdom.

Augustus III left everything to his omnipotent minister, Heinrich, count von Brühl, and Brühl entrusted the government of Poland to the noble family of the Czartoryskis, who had close relations of long standing with the court of Dresden. "The Family," as their opponents sarcastically called them, were to dominate Polish politics for the next half-century, and they were honourably determined to save the republic by a radical constitutional reconstruction which was to include the abolition of the *liberum veto* and the formation of a standing army.

Unfortunately, the other great families of Poland were obstinately opposed to any reform or, as they called it, any "violation" of the existing constitution. The Potockis, in particular, whose possessions in southern Poland and the Ukraine covered thousands of square miles, hated the Czartoryskis and successfully obstructed all their efforts. During the reigns of the two Saxon kings, every *sejm* was dissolved by the hurlings of some great lord or, still worse, of some foreign potentate.

It was against this primitive state of things that the Czartoryskis struggled and struggled in vain. First they attempted to abolish the *liberum veto* with the assistance of the Saxon court, but fear of foreign complications and the opposition of the Potockis prevented anything from being done. Then they broke with their old friend Brühl and turned to Russia. Their chief intermediary was their nephew Stanislaw Poniatowski (see STANISLAUS II AUGUSTUS), whom they sent, as Saxon minister, to the Russian court in the suite of the English minister Sir Charles Hanbury Williams in 1755. The handsome and insinuating Poniatowski speedily won the susceptible heart of the grand duchess Catherine, but he won nothing else and returned to Poland in 1759 somewhat discredited. Nevertheless, the Czartoryskis looked to Russia again for support on the death of Augustus III. They rejected with scorn and derision the pacific overtures of their political opponents, Prince Fryderyk Michał Czartoryski openly declaring that he preferred the tyranny of the Muscovite to the tyranny of his equals. He had in fact already summoned a Russian army corps to assist him to reform his country, which sufficiently explains his own haughtiness and the unwonted compliance of the royal magnates.

Stanislaw II Poniatowski and the Partitions, 1764–95.—The simplicity of the Czartoryskis was even more mischievous than their haughtiness. Their naive expectations were very speedily disappointed. Catherine II and Frederick II had already determined (treaty of St. Petersburg, 1764) that the existing state of things in Poland must be maintained, and as early as 1763 Catherine had recommended the election of Stanislaw Poniatowski as "the individual most convenient for our common interests." The personal question did not interest Frederick, so long as Poland was kept in an anarchical condition he cared not who was called king. Moreover, the opponents of the Czartoryskis made no serious attempt to oppose the entry of the Russian troops.

Shortly afterward Stanislaw Poniatowski was elected king and crowned. But at the beginning of 1766 Prince Nikolai Repnin was sent as Russian minister to Warsaw with instructions which can only be described as a carefully elaborated plan for destroying the republic. The first weapon employed was the question of the dissidents. At that time the population of Poland was, in round numbers, 11,500,000, of whom about 1,000,000 were dissidents or dissenters. Half of these were the Protestants of the towns of Polish Prussia and Great Poland, the other half was composed of the Orthodox population of Lithuania. The dissidents had no political rights, and their religious liberties had also been unjustly restricted, but two-thirds of them being agricultural labourers and most of the rest artisans or petty tradesmen, they had no desire to enter public life and were so ignorant and illiterate that their new protectors, on a closer acquaintance, became heartily ashamed of them. Yet it was for these persons that Repnin, in the name of the empress, now demanded absolute equality, political and religious, with the gentlemen of Poland. He was

well aware that an aristocratic and Catholic assembly like the *sejm* would never concede so preposterous a demand.

Early in 1767 the malcontents, fortified by the adhesion of the leading political refugees, formed at Radom a confederation whose first act was to send a deputation to St. Petersburg, petitioning Catherine to guarantee the liberties of the republic. With a carte blanche in his pocket, Repnin proceeded to treat the *sejm* as if it were already the slave of the Russian empire. But despite threats, wholesale corruption and the presence of Russian troops outside and even inside the chamber of deputies, the patriots, headed by four bishops, offered a determined resistance to Repnin's demands. Only when brute force in its extremest form had been ruthlessly employed, only when two of the bishops and some other deputies had been arrested in full session by Russian grenadiers and sent as prisoners to Kaluga, did the opposition collapse. The *liberum veto* and all the other ancient abuses were now declared unalterable parts of the Polish constitution, which was placed under the guarantee of Russia. All the edicts against the dissidents were, at the same time, repealed.

Confederation of Bar—This shameful surrender led to a Catholic patriotic uprising, known as the Confederation of Bar, which was formed in 1768 at Bar in the Ukraine, by a handful of small squires. It never had a chance of permanent success, though, feebly fed by French subsidies and French volunteers, it lingered on for four years, until finally suppressed in 1772. But, insignificant itself, it was the cause of great events. Some of the Bar confederates, scattered by the Russian regulars, fled over the Turkish border, pursued by their victors. The Turks, already alarmed at the progress of the Russians in Poland and stimulated by Charles Gravier, comte de Vergennes, at that time French ambassador at Constantinople, at once declared war against Russia. Seriously disturbed at the prospect of Russian aggrandizement, the courts of Berlin and Vienna conceived the idea that the best mode of preserving the equilibrium of Europe was for all three powers to readjust their territories at the expense of Poland. Negotiations led to no definite result at first; then Austria took the first step by occupying, in 1769, the county of Spiz (Szepcs, Zips), which had been hypothecated by Hungary to Poland in 1411 and never redeemed. This act decided the other powers; in June 1770 Frederick surrounded with a military cord, ostensibly to keep out the cattle plague, those of the Polish provinces that he coveted. Catherine's consent had been previously obtained.

First Partition, 1772—The first treaty of partition was signed at St. Petersburg between Prussia and Russia on Feb. 6-17, 1772, the second treaty, which admitted Austria also to a share of the spoil, was signed on Aug. 5-16 the same year. The consent of the *sejm* to this act of brigandage was extorted by bribery and force in 1773. Russia obtained the palatinates of Vitebsk, Polotsk, Mscislaw 34,616 sq. mi. of territory, with a population of 550,000. Austria got Little Poland without Cracow and also Lwow, Tarnopol and Halicz and, by corrupting the name of the last, called the new province Galicia: 32,045 sq. mi., with a population of 816,000. Prussia received the palatinate of Pomorze minus Danzig, the palatinate of Chelmino minus Torun, the northern half of Great Poland and the palatinates of Marenburg and Warmia, calling the new acquisition West Prussia 14,025 sq. mi., with a population of 378,000. The total area of Poland before 1772 was about 283,200 sq. mi., with an estimated population of 8,750,000.

The partitioning powers presented Poland with a new constitution. The elective monarchy and the *liberum veto* were of course retained. Poland was to be dependent on its despoilers, but they evidently meant to make it a servicable dependent. The government was henceforth to be in the hands of a permanent council of 36 members, 18 senators and 18 deputies, elected biennially by the *sejm* in secret ballot, subdivided into the five departments of foreign affairs, police, war, justice and the exchequer, whose principal members and assistants, as well as all other public functionaries, were to have fixed salaries. The royal prerogative was still further reduced. The king was indeed the president of the permanent council, but he could not summon the *sejm* without its consent and in all cases of preferment was bound to select one out of three of the council's nominees. Still, the new organization

made for order and economy and enabled Poland to develop and husband its resources and devote itself uninterruptedly to the now burning question of national education.

The shock of the first partition had a certain salutary effect on national mentality. Already in the darkest days of Saxon rule, important educational reforms had been carried out in the schools of the Piarist order by Stanislaw Konarski. Now, the dissolution of the Jesuit order in 1773, putting its rich possessions and the system of schools conducted by it into the hands of the state, gave Poland opportunity to secularize as well as modernize the whole educational fabric of the nation. This huge task was admirably performed by the Commission of National Education, the first ministry of education in Europe. It reorganized both the program of teaching and the structure of the schools—including the decayed universities of Cracow and Wilno—in a thoroughly modern and truly enlightened way. Less progress was made with the cause of constitutional reform: the chancellor Andrzej Zamoyski indeed drafted a new comprehensive code of laws, in which a beginning was made with the emancipation of the peasant serfs and of the town population, but this was rejected by the gentry in the *sejm* (1780).

In the meantime, important events in the international field seemed to give Poland another chance of reasserting its independence against its despoilers. The death of Frederick the Great in 1786 loosened the bonds of the alliance between Prussia and Russia. Russia, drawing nearer to Austria, undertook, jointly with Austria, a war against Turkey which proved unexpectedly hard, and Russia was at the same time attacked by Sweden. Prussia, having changed its policy and concluded an alliance against Russia with England and Holland, was now emboldened by Russia's difficulties to go further. It invited Poland also to forsake the Russian alliance and offered to place an army corps of 40,000 men at its disposal.

The Constitution of May 1791—It was under these exceptional circumstances that the "four years' *sejm*" assembled (1788). Its leaders, Stanislaw Malachowski, Hugo Kollontaj and Ignacy Potocki, were men of character and capacity, and its measures were correspondingly vigorous. Within a few months of its assembling it had abolished the permanent council, enlarged the royal prerogative, raised the army to 65,000 men, established direct communications with the western powers, declared its own session permanent and finally settled down to the crucial task of reforming the constitution on modern lines. But the difficulties of the patriots were commensurate with their energies, and though the new constitution was drafted as early as Dec. 1789 it was not till May 1791 that it could safely be presented to the *sejm*. Meanwhile, Poland endeavored to strengthen its position by an alliance with Prussia. Frederick William II stipulated at first that Poland should surrender Danzig and Torun; but the Poles proving obstinate and Austria simultaneously displaying a disquieting interest in the welfare of the republic, Prussia in 1791 concluded an alliance with Poland which engaged the two powers to guarantee each other's possessions and render mutual assistance in case either were attacked.

But external aid was useless so long as Poland was hampered by its anarchical constitution. The most indispensable reforms had been frantically opposed; the debate on the reorganization of the army alone had lasted six months. It was only by an audacious surprise that Kollontaj and his associates contrived to carry through the new constitution. Taking advantage of the Easter recess, when most of the malcontents were out of town, they suddenly, on May 3, brought the whole question before the *sejm* and demanded urgency for it. Before the opposition could remonstrate, the marshal of the *sejm* produced the latest foreign dispatches, which unanimously predicted another partition, whereupon, at the solemn adjuration of Ignacy Potocki, King Stanislaw exhorted the deputies to accept the new constitution as the last means of saving their country and himself set the example by swearing to defend it.

The constitution of May 3, 1791, converted Poland into a hereditary limited monarchy, with ministerial responsibility and biennial parliaments. The *liberum veto* and all the intricate and

obstructive machinery of the anomalous old system were forever abolished. All invidious class distinctions were done away with. The towns, in a special bill confirmed by the new constitution, got full administrative and judicial autonomy, as well as a certain measure of parliamentary representation, the personal privileges of the gentry, such as possession of land and access to office in the state and in the church, were thrown open to the townsmen. The peasants were placed under the protection of the law, and their serfdom was mitigated with a view to its entire abolition. Absolute religious toleration was established. Provision was made for further periodical reforms by subsequent parliaments.

The constitution of May 3 had scarcely been signed when Stanislaw Feliks Potocki, Seweryn Rzewuski and Kaszimir Brzozowski, three of the chief dignitaries of Poland, hastened to St. Petersburg and there entered into a secret convention with the empress, whereby she undertook to restore the old constitution by force of arms but at the same time promised to respect the territorial integrity of the republic. Entering Polish territory with Russian troops, the conspirators formed a confederation at the little town of Targowica in the Ukraine, protesting against the new constitution as tyrannous and revolutionary, at the same time the new Russian minister at Warsaw presented a formal declaration of war to the king and the *sejm*. The *sejm* met the crisis with dignity and firmness. The army was at once dispatched to the frontier, the male population was called to arms, and Ignacy Potocki was sent to Berlin to claim the assistance stipulated by the treaty of March 19, 1791. The king of Prussia, in direct violation of all his oaths and promises, declined to defend a constitution which had never had his "concurrence." Thus Poland was left entirely to its own resources. The little Polish army of 46,000 men, under Prince Joseph Anthony Poniatowski, nephew of King Stanislaw II, and Tadeusz Kosciuszko, did all that was possible under the circumstances. For more than three months they kept back the invader, and, after winning three pitched battles, retired in perfect order on the capital (see KOSCIUSZKO, TADEUSZ ANDRZEJ BONAVENTURA, PONIATOWSKI, JOSEPH ANTHONY). But the king, and even Kollontaj, despairing of success, now acceded to the confederation, hostilities were suspended, the indignant officers threw up their commissions; the rank and file were distributed all over the country, the reformers fled abroad, and the constitution of May 3 was abolished by the Targowicians as a "dangerous novelty." The Russians then poured into eastern Poland, the Prussians, at the beginning of 1793, alarmed lest Catherine should appropriate the whole republic, occupied Great Poland, and a diminutive, debased and helpless *sejm* met at Grodno in order, in the midst of a Russian army corps, "to come to an amicable understanding" with the partitioning powers.

Second Partition, 1793.—After every conceivable means of intimidation had been unscrupulously applied, the second treaty of partition was signed at three o'clock on the morning of Sept. 23, 1793. By this *pactum subjectionis*, as the Polish patriots called it, Russia got all the eastern provinces of Poland, extending from Livonia to Moldavia, comprising a territory of 96,751 sq. mi., while Prussia got Dobrzyn, Kujavia, Great Poland, Torun and Danzig. Poland was now reduced to less than one-third of its original dimensions, with a population of about 3,500,000.

Kosciuszko and the Third Partition.—The focus of Polish nationality was now transferred from Warsaw, where the Targowicians and their Russian patrons reigned supreme, to Leipzig, whither the Polish patriots, Kosciuszko, Kollontaj and Ignacy Potocki among the number, assembled from all quarters. From the first they meditated a national rising, but their ignorance, enthusiasm and simplicity led them to commit blunder after blunder. The first of such blunders was Kosciuszko's mission to Paris in Jan. 1793. He was full of the idea of a league of republics against the league of sovereigns; but he was unaware that the Jacobins themselves were already considering the best mode of detaching Prussia, Poland's worst enemy, from the anti-French coalition. Kosciuszko received an evasive reply and returned to Leipzig empty-handed. In the meantime, certain officers in Poland had revolted against the reduction of the Polish army to 15,000, imposed upon the country by the partition treaty. Kosciuszko him-

self condemned their hastiness; but the march of events forced his hand, and in March 1794 he went to Cracow, proclaimed a national insurrection and assumed the powers of a dictator. He called the peasants to arms, and they responded nobly, in return for which he supplemented the provisions of the constitution of 1791 by a manifesto giving them complete freedom. At first, Kosciuszko's arms were almost universally successful. The Russians were defeated in more than one pitched battle, three-quarters of the

FIG. 2.—PARTITIONS IN THE 18TH CENTURY

ancient territory was recovered, and Warsaw and Wilno, the capitals of Poland and Lithuania, respectively, were liberated. The first serious reverse at Szczekocin, was more than made up for by the successful defense of Warsaw against the Russians (July 9–Sept. 6). But even during that heroic defense mob lawlessness in Warsaw and violent dissensions in the supreme council and in the army began to frustrate the superhuman efforts of the unfortunate but still undaunted dictator. The appearance of overwhelming masses of Russian troops, together with the open hostility of Austria as well as Prussia, did the rest, and Kosciuszko's insurrection received its deathblow on the battlefield of Maciejowice, where he himself was wounded and taken prisoner. Warsaw was taken amid a terrible massacre of the population in the suburb of Praga, and the remainder of the troops capitulated a few weeks later.

The greed of the victorious powers nearly led to a rupture between Austria and Prussia, but, after some dissensions, the third partition of Poland was effected by successive treaties in 1795 and 1796. Austria had to be content with Lublin, Siedlec, Radom and Kielce, while Prussia took Suwalki, Bialystok, Lomza and Warsaw. Russia annexed all the rest and was afterward to tear even parts of their booty from the two others. Thus the name of Poland was wiped from the map of Europe, to reappear only after more than a century.

(R. N. B., R. Dy., X.)

THE DUCHY AND FOREIGN RULE

After the third partition, the more high-spirited Poles, chiefly officers and soldiers of Kosciuszko's army, emigrated and formed, on Italian soil, the Polish legions; which, during the next ten years, fought the battles of the French republic and of Napoleon all over Europe and even outside it, from Egypt to the West Indies. They were commanded by Jan Henryk Dombrowski, one of Kosciuszko's ablest generals, but Kosciuszko himself stood aloof, distrusting Napoleon.

The Duchy of Warsaw.—In 1806 and 1807, when Napoleon

defeated Prussia and engaged in a war with Russia, Polish soldiers once more appeared on Polish soil, and the hopes of the nation seemed near fulfilment. In fact, the peace of Tilsit resulted in the reconstruction of a Polish state out of the central provinces of Prussian Poland, but Napoleon's anxiety to conciliate Russia effectually prevented him from making his new creation large enough to be self-supporting. The duchy of Warsaw, as it was called, consisted in 1807 of territories taken by Prussia in the second and third partitions, to which territory seized by Austria in the third partition was added in 1809. The total area of the duchy was then about 64,000 sq. mi., with a population of about 4,350,000. The constitution was dictated by Napoleon; it was framed on the French model and on very advanced lines. Equality before the law (implying personal freedom of the peasant), absolute religious toleration and highly developed local autonomy were its salient features. The king of Saxony, Frederick Augustus I (previously elector as Frederick Augustus III, grandson of Augustus III of Poland), whom Napoleon made duke, took the initiative in all legislative matters, but the administration was practically controlled by the French. In spite of being subject to most burdensome financial and military exigencies for the purposes of Napoleon's continuous wars, the small duchy contrived, during the few years of its existence, to do much peaceful, productive, organizing work, especially in the educational and economic spheres.

Poland's hopes for greater things revived once more when Napoleon announced his war against Russia (1812), as his "second Polish war." The duchy, by an immense effort, put an army corps of nearly 98,000 men into the field. But the calamity that overtook Napoleon in Russia also sealed the fortunes of the duchy. The remainder of the Polish troops faithfully followed Napoleon in his campaign of 1813-14, during which the heroic leader of the Poles, Prince Joseph Anthony Poniatowski, perished in covering the emperor's retreat from Leipzig. The duchy was occupied by the Russians.

The Congress Kingdom and Russian Rule.—Tsar Alexander I had been united by youthful friendship to the most eminent Polish noble of his time, Prince Adam Czartoryski, and had even made him, on his accession, foreign minister of the Russian empire. On Napoleon's downfall the Poles, to whom Alexander did not spare promises and flatteries, entertained the highest hopes.

It was not Alexander's fault, indeed, if the congress of Vienna, because of jealousy among the great powers and the entanglement of the Polish question with that of Saxony and other territories, did not lead to a reunion of Poland, even under the Russian sceptre, but confirmed the division of the country among the three partitioning powers. Cracow only, with a small surrounding territory, was erected into a free city republic. Great Poland, with Poznan for its centre and a population of 850,000, was left to Prussia. Austria remained in possession of Galicia with 1,500,000 inhabitants. The eastern borderlands, from Lithuania and White Russia to Volhynia and the Ukraine, continued to be incorporated in Russia. The remnant of central Poland only—about three-fourths of the territory of Napoleon's duchy of Warsaw—was constituted as the so-called Congress kingdom under the emperor of Russia as king of Poland. Guarantees of home rule in all parts of the divided country and of free communication between them were given by all powers concerned, only to prove soon more or less futile.

Alexander, who had a sentimental regard for freedom, so long as it meant obedience to himself, had promised the Poles a constitution. That constitution was soon duly drafted and signed. It contained 165 articles divided under seven heads. The kingdom of Poland was declared to be united to Russia in the person of the tsar, as a separate political entity. Lithuania and the Ruthenian palatinates continued to be incorporated with Russia as the Western Provinces and were divided from the Congress kingdom by a customs barrier till the reign of Nicholas I. The kingdom of Poland thus defined was to have at its head a lieutenant of the emperor (*namesnik*), who must be a member of the imperial house or a Pole. The first holder of the office, Gen. Józef Zajonczek (1752-1826), was a veteran who had served Napoleon

Roman Catholicism was recognized as the religion of the state, but other religions were tolerated. Liberty of the press was promised, subject to the passing of a law to restrain its abuses. Individual liberty, the use of the Polish language in the law courts and the executive employment of Poles in the civil government were secured by the constitution. The machinery of government included a council of state (at which the imperial government was represented by a commissioner plenipotentiary) and a *sejm* divided into a senate, composed of the princes of the blood, the palatines and councillors named for life, and a house of deputies elected for seven years. Poland retained its flag and a national army based on that which had been raised by and had fought for Napoleon. The command of the army was given to the emperor's brother Constantine, a man of somewhat erratic character, who did much to offend the Poles by violence (see CONSTANTINE PAVLOVICH).

The *sejm* met three times during the reign of Alexander, in 1818, in 1820 and in 1825, and was on all three occasions opened by the tsar. But the tsar and the *sejm* soon quarrelled. The third session of the *sejm* (May 13 to June 13, 1825) was a mere formality. All publicity was suppressed, and one whole district was disfranchised because it persisted in electing candidates who were disapproved of at court. All Europe at the time was seething with secret societies organized to combat the reactionary governments of the Holy Alliance. In Poland the National Freemasonry, or National Patriotic society as it was afterward called, had a large membership, especially among the students and the younger officers. Outside Congress Poland, a similar student movement arose in the University of Wilno. Severe measures—imprisonment, deportation and exile—were taken against students and graduates of Wilno (including the poet Adam Mickiewicz), and they added to the excitement in Warsaw.

No open breach occurred during the reign of Alexander I, nor for five years after his death in 1825. On the death of the unpopular Zajonczek in 1826, the grand duke Constantine became imperial lieutenant. His brother, the new tsar Nicholas I, soon became entangled in a war with Turkey. Austria, as usual, desirous of profiting by Russia's difficulties, began to court the favour of the Poles. Nicholas was crowned king of Poland in Warsaw in 1830 and personally opened the *sejm* in 1830. But the *sejm* already in 1828 had refused to sentence to death a group of Polish conspirators accused of dealings with the Russian "Decembrists" who had plotted Nicholas' overthrow, and in 1829 there was even an abortive Polish plot to murder him at his coronation in Warsaw. Fresh excitement was created in Poland by the outbreak of the Revolution in France in July 1830 and the revolt of Belgium, a rumour was current—not without justification—that Nicholas, acting in concert with the other autocrats of the Holy Alliance, intended to use the Polish army to coerce the French and Belgian revolutionaries.

The Rising of 1830.—On Nov. 29, 1830, a military revolt broke out in Warsaw. It was started by the young hotheads of the officers' training school and began with the murder of several senior officers loyal to the government. Regiments of the army and masses of the civilian population began to join the rising, the weakness of Constantine allowed it to gather strength. He evacuated Warsaw and finally left the country. The war lasted from Jan. till Sept. 1831. The Poles began with some chances of success, they had a well-drilled and well-equipped army of about 30,000 men, which they increased by recruiting to about 80,000. Against this, the Russians, with considerable difficulty, succeeded in putting only about 114,000 men into the field. Their ultimate success resulted partly from the friendly attitude of Prussia, partly from the fact that the Polish *sejm*, having proclaimed the deposition of the tsar at an early stage of the conflict, received no response to its appeal for western European protection. But to a large extent the defeat of the insurrection was caused by certain faults on the Polish side: want of ability and decision on the part of the generals, a succession of rapid changes in the command of the army, fierce party strife within the civil government in the capital, a deplorable outbreak of mob violence in Warsaw at a critical moment of the war, and, finally, an irresolute attitude of

the insurrectionary parliament toward the peasant claims

After the suppression of the insurrection, certain remnants of a constitution were still granted to Russian Poland by the "organic statute" of 1832, but they were soon rendered illusory, the administration avowedly aimed at destroying the nationality and even the language of Poland. The universities of Warsaw and Wilno were suppressed, the Polish students compelled to go to St. Petersburg and Kiev. The recruits from Poland were distributed in Russian regiments, and the use of the Russian language was enforced as far as possible in the civil administration and in the law courts. The customs barrier between Lithuania and the former Congress Poland was removed, in the hope that Russian influence would spread more easily over Poland. A hostile policy was adopted against the Roman Catholic Church. But though these measures cowed the Poles, they failed to achieve their main purpose. Polish national sentiment was intensified. The Poles in Russia, whether at the universities or in the public service, formed an element which refused to assimilate with the Russians. In Poland itself the tsar left much of the current civil administration in the hands of the nobles, whose power over their peasants was hardly diminished and was misused as of old. The Polish exiles who filled Europe after 1830 maintained a constant agitation from abroad. The stern government of Nicholas was, however, so far effective that Poland remained quiescent during the Crimean War.

Alexander II and the Rising of 1863.—The reign of the new tsar Alexander II began with certain concessions to Poland in the political and educational field. Exiles were allowed to return, administrative pressure was lightened, the church was propitiated, an "agricultural society" was allowed to be formed and to discuss important affairs of the community, a medical faculty and, later on, a complete university were re-established in Warsaw. Finally, even a Polish council of state and a Polish administrative apparatus for the kingdom began to be organized. In their later stages these reforms were the work of Count Alexander Wielopolski, who was installed in high office and stood for a national policy of loyal union with Russia. But his autocratic temper lost him the sympathies of the moderate elements of the gentry, while, on the ardent minds of the young, Wielopolski's methods acted like fuel heaped on fire. Religious ceremonies were used as the occasion for demonstrative political processions, there were collisions with the Russian troops and victims fell in the streets of Warsaw. Wielopolski had the unhappy idea of causing the revolutionary youth of the cities to be recruited en masse for the Russian army, the plan became known, numbers of the young people fled into the forests, and a revolutionary committee on Jan. 22, 1863, started an ill-prepared insurrection.

The struggle of the ill-equipped and ill-organized insurgent bands against the Russian garrisons dragged on in the form of guerrilla warfare throughout the country for nearly two years. A secret national government was set up in Warsaw, the movement spread successfully into Lithuania and the insurrection occupied the diplomatic attention of western Europe. But the assistance promised by Napoleon III never became effective, the rising was crushed; wholesale executions, confiscations and deportations followed its suppression, and Poland was now definitely turned into a Russian province.

Russification.—All self-government in Congress Poland was suppressed in 1863; all education was russified in 1869, justice in 1873. On the other hand, the abolition in 1851 of the customs frontier between Russia and Poland had laid the foundation for an extraordinary industrial expansion. Russian Poland, with its great textile factories at Lodz, became the chief industrial region for all Russia. Its vast market in agricultural Russia was protected against western competition by high tariffs; the Russian government took every possible measure (such as the introduction of specially favourable railway tariffs) to assist this expansion. The Poles, being excluded from state service in their own country, busied themselves with productive occupations, and the upper and middle classes achieved a well-being far superior to anything enjoyed by their cousins in Galicia. A second result of this expansion was the growth in Congress Poland of a large and radical proletariat which made common cause with the Russian Social

Democratic movement. In the country districts, the agrarian policy of the Russian government was expressly calculated to stir up ill-feeling between the Polish peasants, whom the government demonstratively took under its protection, and the country gentry, whom it was determined to punish in every way for the leading part they had played in the insurrections. The peasant of Russian Poland officially got his freedom from the tsar in 1864. All peasants, whatever their tenure had been, and the mass of the landless proletariat became freeholders, on a far more generous basis than the Russian peasant in 1861. The landlords received compensation in the form of Russian treasury bonds, which stood far below par, and the peasants got the right to use the landlords' pastures and woods.

In the sphere of education, the most thoroughgoing system of russification set in after 1864. All the revived Polish schools of the Wielopolski period were made Russian again, including the University of Warsaw, and no effort was spared to produce in the minds of youth a distorted image of Poland's past. Secret patriotic education, however, counteracted this policy successfully both in town and country, and private Polish schools, struggling against great difficulties, kept the Polish cultural tradition alive.

The civil government of Russian Poland was reorganized strictly on the model of the rest of the Russian empire, the Poles being debarred, however, from certain liberal institutions which the Russians by that time possessed, such as municipal self-government and trial by jury. The Russian language was made compulsory in all official relations and at a later time even in the records of private institutions. A corrupt Russian bureaucracy filled all government offices, a severe censorship strangled every free utterance of the nation in the press and in literature, and a drastic police regime kept the prisons filled with political offenders.

After Russia's defeat in the Japanese war of 1904, the outbreak of a revolution in 1905 kindled all Polish hopes once more. A constitution was granted to the Russians, and 36 Polish deputies sat in the first Russian parliament (duma). A certain measure of freedom in the educational field was obtained and eagerly used for the foundation of new schools by a Warsaw society called the Mother of Schools (*Macierz Szkolna*). The peasants of Russian Poland spontaneously introduced the Polish language in their self-governing bodies. In the duma itself, the Liberals were not averse to granting Poland a large measure of autonomy within Russia. At the same time, persecution in Prussian Poland increased under Prince Bernhard von Bülow, while the Ukrainian national movement, developing in Austrian Poland especially since the grant of universal suffrage in 1907, was unwelcome both to Poles and Russians. Under these circumstances, Russian propaganda, reviving the pan-Slav ideals of 30 years ago, could count on some success even among the Poles. There were gestures of reconciliation at two Slav congresses, in 1908 and 1910, the Czechs willingly acting as mediators. The idea of uniting all Poles with autonomy within the Russian empire was widely preached, it became the program of the National Democratic, or all-Polish, party, led by Roman Dmowski, the head of the Polish representation in the duma.

Opposed to Dmowski and the followers whom he found even among Austrians, Poles there stood the irreconcilable revolutionaries, led by Joseph Pilsudski. Both the insurrectionary movement started by Pilsudski in 1905 and the constitutional endeavour of Dmowski and his friends in the duma were soon stifled by the Russian reaction of the Peter Stolypin period. Pilsudski took refuge in Galicia and began to organize armed resistance to Russia from that base. In the duma, the Polish representation was lowered from 36 to 10 deputies. In the country, all the liberties gained after 1905 soon disappeared. The government's purchase of the railway line from Warsaw to the Austrian frontier resulted in the removal of all Polish railwaymen from the service and was a great blow to the Polish element. In 1912 the separation of the district of Chełm, in the southeast of Russian Poland, from the body of the province and its incorporation in Russia proper was received with indignant protests by Polish opinion as a new partition of Poland.

Prussian Poland.—The regime in Prussian Poland during the

first 15 years after the congress of Vienna had been endurable. A Polish nobleman related by marriage to the Prussian dynasty—Prince Antoni Radziwiłł—was appointed lieutenant governor of the province, there was a provincial assembly and local representative bodies both urban and rural. The landowners were allowed to organize for economic purposes, and the peasants were fully enfranchised in 1823. After the insurrection of 1830, a period of more oppressive government by a German provincial president E. Flottwell, set in, he revived Frederick the Great's method of German colonization of the Polish province, and he began to germanize the administration and the school system. A period of new concessions to the Poles under Frederick William IV was interrupted by the revolution of 1846–48. The constitution with which Prussia emerged from the revolution put an end to the self-government of Prussian Poland. Another interval of relaxation, in the first years of William I, was soon succeeded by the period of Bismarck's and Bulow's resolutely anti-Polish policy—characterized by the *Kulturkampf*, the "Colonizing committee," the Wieszna scandal, the schools' strike, the Expropriation bill and the like, for an account of which see POZNAN. The result of the Prussian methods was to create a sturdy class of peasants and small *bourgeoisie*, disciplined and economically and culturally advanced, and a fellow feeling arose between the peasants and the landowning gentry such as was hardly known in other parts of Poland.

Austrian Poland—After the insurrection of 1830–31, no remnant of Poland's independent political existence had been left except the minute city republic of Cracow, created by the congress of Vienna. For 30 years this miniature state led a flourishing existence. When the ferment of the approaching European revolution of 1848 was stirring most continental countries to their depths, there were active preparations for another rising both in Austrian and Prussian Poland. For Austria the menace was diverted by a peasant revolt in Galicia in Feb. 1846, which led to a massacre of about 2,000 landowners by the peasantry incited by the Austrian governor general Baron Krieg von Hochfelden. At the same time, Austria availed itself of the unrest among its Poles to obtain the consent of Russia and Prussia to the suppression of the city republic of Cracow. But it was not until 1848 that Cracow was finally occupied by Austria and incorporated into Galicia.

Austria under the old autocratic regime oppressed its Polish province politically and exploited it economically in the most ruthless fashion. The revolution of 1848 brought a change, but not until the defeat of Austria by Prussia in 1866 was it realized at Vienna that only a more liberal policy could hold the tottering, mixed monarchy together. The relation with Hungary having been placed on a federal footing, concessions had to be granted to the strong Polish element in Austria. The Poles began to be active in Austrian politics. The numerical strength of Polish deputies in the Vienna parliament was such that no Austrian government could be formed without it. Galicia (as Austrian Poland was officially called), containing a large Ukrainian element in its eastern half, was granted a special minister to represent its interests in the Vienna cabinet. It also got a provincial legislative assembly and a governor, who was invariably appointed from the ranks of the Polish aristocracy. With purely Polish administration, schools and courts of law, Galicia became indeed almost an independent Polish state within Austria and successfully defied the centralizing efforts of the Vienna bureaucracy. The Polish landowning class, which practically governed the country for the next few decades, managed its affairs in a one-sidedly agrarian spirit, the interests of the towns were not properly considered, hardly any attention was given to the development of industries, and Galicia remained economically backward. Even its oil fields were largely developed by foreign capital. On the other hand, political and cultural activities had more scope than in the two other parts of Poland, Galicia became the "Piedmont" of the Polish national movement, and Cracow, with its old university and new Academy of Sciences, an intellectual, artistic and literary centre for the whole nation. With the growth of a new educated class and the introduction of universal suffrage in Austria (1907) the social structure of the country began to change, its politics were strongly democratized,

new economic tendencies got the upper hand, and Galicia was at last on the road of material advance when World War I began.

World War I.—World War I found the Poles estranged from one another and without a united national policy. "Brygadier" Pilsudski crossed the frontier from Galicia with a few hundred of his legion and engaged the Russian empire in battle as forerunner of the army of an independent and united Poland. But the Polish Supreme committee, formed in Cracow on Aug. 16, aimed at uniting Galicia and Congress Poland as a third party in the dual monarchy and required the Polish legion to take the oath to the emperor. In Warsaw the Polish National committee under Dmowski denied the right of the Cracow committee to speak in the name of the Polish nation, protested loyalty to the tsar and attempted to form a Polish legion on the side of Russia. Meanwhile the grand duke Nicholas issued a proclamation (Aug. 14) in which he promised to unite the three parts of Poland in an autonomous state with the Russian empire.

In the summer of 1915, however, the Central Powers conquered all Congress Poland. After the fall of Warsaw on Aug. 5, 1915, military governments were set up on behalf of Germany at Warsaw and of Austria-Hungary at Lublin. But fresh difficulties confronted the Austrian solution. The Polish Socialist party (P.S.) under Pilsudski declared that no recruiting should take place for Polish legions until an independent Polish government had been formed to conduct it. Meanwhile, Istvan Tisza, the Hungarian premier, had vetoed the Austrian trialist scheme, which was also opposed by Germany. Vienna again rejected the plans put forward by Germany of annexing Congress Poland to Germany or of forming an independent Polish buffer state in economic, military and political alliance with the Central Powers.

In Aug. 1916, however, after the defeat of the Austro-Hungarian troops at Luck, the German supreme command acquired complete control of policy on the eastern front. Erich Ludendorff believed it possible to gain a large Polish army if his ideas were adopted. Germany and Austria-Hungary issued a proclamation on Nov. 5, 1916, holding out a prospect of the restoration of an independent Congress Poland as a hereditary constitutional monarchy closely attached to the Central Powers. Francis Joseph promised Galicia increased autonomy within Austria-Hungary. The discussion of details was shelved; the military governments at Warsaw and Lublin continued to administer the country. On Nov. 26, 1916, a provisional council of state of 25 members was appointed, it was solemnly opened on Jan. 14, 1917. Pilsudski, who was one of the members of the council, began to work out the plans for a national Polish army. He refused, however, to raise it for German use, and the German plan of raising a Polish army failed completely.

In March 1917 the Russian dynasty fell. On March 30 the new Russian government recognized Poland's right to self-determination and promised the creation of a new Polish state. These events altered the attitude of the Allies toward Poland, particularly as they were now reinforced by the entry of the United States into the war. The answer of the Entente Powers to the peace proposals of the Central Powers issued on Jan. 10, 1917, had already declared their adhesion to the tsar's manifesto to his armies (Dec. 25, 1916) which had spoken of "the formation of a free Poland in all parts into which it is at present divided."

The danger still threatening Poland from Russia vanished with the breakdown of Alexander Kerensky's offensive (July 1917). The Central Powers were now the only enemy. In May 1917 the Polish members of the Austrian *reichsrat* unanimously demanded "an independent united Poland with an outlet to the sea," and declared that the Polish case was one for "international consideration." At the same time, the Polish council of state in Warsaw asked the occupants for a widening of its powers and split up over the German demand for a recruiting appeal and an oath of loyalty. Pilsudski resigned from the council with his adherents and set about turning his secret military organization against Germany.

On July 22 Polish discontent was increased by the arrest of Pilsudski. On Aug. 25 the council of state, now discredited with the people, resigned. On Sept. 12 Germany and Austria-Hungary introduced a new project of a regency of three, a cabinet and premier and council of state, elected but enjoying limited powers,

the German and Austrian military governments retaining the right of veto. The regency was appointed on Oct 15, it consisted of the archbishop of Warsaw, Aleksander Kakowski, Prince Zdzislaw Lubomirski and Jozef Ostrowski, a large landowner. The first prime minister, Jan Kucharszewski, was appointed on Nov 26 and formed his first ministry on Dec 7.

While Polish affairs were taking this course under Austro-German occupation, Dmowski was making propaganda for the Polish cause in France and Great Britain and I. J. Paderewski was working tirelessly in the United States. In Nov 1916 the so-called Polish National department in Chicago, Ill., had united all the organizations of the 4,000,000 Poles in the U.S., and under Paderewski's influence, Pres Woodrow Wilson, in his tentative peace message of Jan 22, 1917, alluded to a "united, independent and autonomous Poland." In the course of 1917 a Polish corps was organized by Gen Jozef Dowbor-Musnicki in Russia, and a Polish army began to be formed in France. The Polish National committee, founded by Dmowski and Paderewski at Lausanne in Aug 1917 and later established in Paris, was gaining increasing influence in the councils of the Allies. Between Sept 20 and Dec 1, 1917, France, Great Britain, Italy and the United States had recognized it as the official representative of the Polish people. The 13th of President Wilson's Fourteen Points (Jan 8, 1918) declared that a Polish state should be erected which should include the territories inhabited by indisputably Polish population "with an outlet to the sea and an international guarantee of its independence and integrity."

In the meantime, the utter collapse of the Russian army had led to peace negotiations between the Central Powers and the Bolsheviks. The Bolshevik delegates who arrived at Brest-Litovsk (q.v.) in Dec 1917 recognized, in theory, the right of the Polish people to self-determination, but Polish delegates were not admitted to the deliberations. By the treaty as concluded on March 1, 1918, Soviet Russia renounced all claims over Poland, but the treaty (Feb 9, 1918) between the Central Powers and the Ukraine allotted to the Ukraine the disputed province of Chelm, while Austria-Hungary further pledged itself in a secret clause to form East Galicia and Bukovina into a separate crownland. These clauses became known and Polish opinion was infuriated, the Polish club in the Austrian reichsrat went over to the opposition and the remnant of Pilsudski's legions still fighting for the Central Powers mutined. Some were interned, some, under Gen Jozef Haller, fought their way to the coast and joined the new Polish army in France. The council of state in Poland was opened in Warsaw on June 22. Little interest was taken in it, and general feeling in Poland tended to ignore this body in favour of the National committee in Paris. Even before the breakdown of the German offensive in July 1918, the prime ministers of Great Britain, France and Italy had declared in favour of an independent and united Poland at Versailles on June 3, 1918.

The Declaration of Independence.—On Oct 6 the Polish regency council published a manifesto to the Polish nation declaring its intention of dissolving the council of state, forming a representative national government and summoning a *sejm* for a "free and united Poland." On Oct 15 the Polish representatives in the Austrian reichsrat declared themselves to be "subjects and citizens of a free and re-united Polish State." On Nov 10 Pilsudski, who had been released from imprisonment at Magdeburg on Oct 7, arrived in Warsaw. The German troops of occupation were disarmed and expelled, and the Poles assumed the executive power in Warsaw on Nov 11. The regency council declared on the same day that it appointed Pilsudski to the supreme command of all Polish troops and on Nov 14 resigned in favour of Pilsudski.

On Nov 14, 100, the Polish members of the German reichstag and of the Prussian landtag met in Poznan and formed a supreme popular council. On Dec 27 the Poznanian Poles rose against the Germans and turned them out of their province. Severe fighting broke out and went on till Feb 16, 1919, when an armistice was concluded at Trner by Marshal Ferdinand Foch, acting on behalf of the Allies and Poland. Not until after the treaty of Versailles was signed did Poznan send deputies to the constituent assembly in Warsaw.

POLAND RESTORED

Of all the new or resurrected states of Europe, Poland was in many respects in the most difficult position. The territory of Congress Poland and Galicia had been devastated in the war. Most of the factories that had not been actually dismantled were closed for lack of raw material. The fields of the peasants had been laid waste, their livestock slaughtered, their farms burned. Many districts were actually famine stricken, others swept by epidemics. Communications were disorganized and rolling stock was in a deplorable state. Marks, roubles and crowns circulated freely, but their values were low and uncertain, and public and private finances were chaotic. Because of the past policy of Prussia and Russia, a Polish civil service existed only in Galicia. Thirty thousand German troops were still in the country.

Pilsudski, the old revolutionary, had begun by appointing a cabinet of the left, composed mainly of Galician Socialists and peasants' representatives, under the presidency of Jędrzej Moraczewski. But the propertied classes refused him their support, and his attempt to float an internal loan met with little response. In December Paderewski, the second man in Poland enjoying almost unlimited prestige, arrived in the country, composed his differences with Pilsudski and became premier on Jan 17, 1919. Dmowski was appointed president of the Polish delegation to negotiate peace. It was possible to hold elections for a constituent assembly on Jan 26, 1919. The constituent *sejm* met on Feb 10. It passed a vote of confidence in Paderewski's cabinet and confirmed Pilsudski as head of the state. Paderewski proceeded to Paris to urge Poland's claims, Pilsudski raised an army to defend them. General Haller's 100,000 troops, returning in April from France overland across Germany, were a valuable addition to the 230,000 men then at Pilsudski's disposal. The unification of the army was celebrated on Oct 19, 1919, the French system of instruction and organization was adopted and by the beginning of 1920 the Polish army grew to about 600,000 men in 21 divisions of infantry and 7 brigades of cavalry. (R. Dv.)

The Treaty of Versailles and Frontier Problems.—On June 28, 1919, on behalf of Poland, Dmowski and Paderewski signed the treaty of Versailles, which, however, left the major part of the country's frontiers undefined. Poland regained Pomorze and Poznan, but in East Prussia and Upper Silesia the Polish-German frontier was to be decided by plebiscite. Danzig (q.v.) was to be a free city under the protection of the League of Nations but was to be included within the Polish customs frontier in order to provide Poland with a free and secure access to the sea, in addition, Poland was to have free, unrestricted use of the port and to undertake the conduct of the free city's foreign relations. There was a Polish-Czechoslovakian dispute over Teschen (Cieszyn or Tesin) and also over the territories of Orawa (Orava) and Spisz. Of the eastern frontiers of Poland article 87 of the treaty stated that they would be "subsequently determined by the principal Allied and Associated Powers."

East Prussia.—Two plebiscite zones were established, that of Marienwerder (Kwidzyn), an area of 1,036 sq mi with 174,000 inhabitants, and that of Allenstein (Olsztyn), about 4,800 sq mi with 565,000. All Prussian civil servants were left in the plebiscite areas and the presence of German security police precluded freedom of speech. The vote was taken on July 11, 1920, when Soviet forces were at the gates of Warsaw. In the Allenstein zone 363,209 votes were cast for Germany and 7,980 for Poland; in the Marienwerder zone 96,923 for Germany and 8,018 for Poland. Making the utmost of a stipulation that not only residents but also persons born in the area had the right to vote, the Germans sent to the plebiscite zones 202,700 "emigrants," who constituted nearly half of the voters, while 40% of the qualified residents abstained from voting. Thus the plebiscite, lost by Poland, could scarcely be described as a fair expression of the popular will. (See also ALLENSTEIN-MARIENWERDER.)

Upper Silesia.—The plebiscite area of Upper Silesia was 4,250 sq mi with 1,042,200 inhabitants. Out of 706,820 votes cast for Germany on March 20, 1921, emigrant voters were responsible for 182,288, Poland obtained 479,414 votes. In all, 682 communes voted for Poland and 792 for Germany, but the Poles secured pre-

ponderance in the southeastern plebiscite area which economically was the most important. Disregarding the treaty provisions for the partition of the area according to the wishes of the inhabitants expressed by communes, Germany claimed the whole of Upper Silesia, while Wojciech Korfanty, the leader of the Silesian Poles demanded that 59% of the area, in which 673 communes voted for Poland and 230 for Germany, be awarded to Poland.

The Inter-Allied commission failed to agree on a unanimous proposal to the Supreme council of the principal Allied Powers, the British and Italian commissioners favouring cession to Poland of only the two southern agricultural districts of Rybnik and Pszczyna (Pless) while the French commissioner proposed a frontier less favourable than the Korfanty line but leaving the industrial basin to Poland. Learning of this basic disagreement, the Polish military organization, of which Michał Grażyński was the chief organizer, thought that only an insurrection could save the Polish cause. Korfanty agreed and gave the order for a rising, which broke out on May 3, 1921. In a few days almost all the area within the Korfanty line was occupied. Taken by surprise, the Germans were thrown back. After six weeks' fighting the Inter-Allied commission effected a cessation of hostilities on June 24, and both the belligerents withdrew their troops.

The Supreme council assembled in Paris on Aug. 8-12 failed to draw a new frontier across Upper Silesia because David Lloyd George was anxious to save for Germany as much of the industrial area as possible. The only way out of the deadlock was to submit the question to the council of the League of Nations, where Great Britain was represented by Arthur James Balfour. The council's verdict, given on Oct. 12, 1921, was endorsed by the Allied Powers eight days later. The new frontier divided the industrial area. Poland was awarded 1,241 sq mi with about 996,000 inhabitants, 76% of the coal production, 22 out of 37 blast furnaces and 9 out of 14 steelworks. Thus a basis for economic independence was assured. (See also SILESIA.)

Teschén—On Nov. 5, 1918, close upon the final dissolution of the Habsburg monarchy, the Polish and Czech National council of Teschen Silesia concluded an agreement dividing the four districts of the province into two ethnographic entities. On Jan. 23, 1919, however, on orders from Prague, the Czech forces fell unexpectedly upon insignificant Polish forces in the area and occupied the greater part of the province. The government of Prague argued that Teschen was historically a Czech land and, moreover, that the new Czechoslovakia needed its coal.

The fighting was stopped by the Supreme council on Feb. 3, 1919. After a vain attempt to reach agreement by direct negotiation, the Supreme council decided on Sept. 27 that the dispute should be settled by plebiscite. On July 10, 1920, Poland, whose existence was menaced by the Soviet offensive, agreed at Spa that the Conference of Ambassadors should draw a final frontier. On July 28 less than half of Teschen Silesia was awarded to Poland (387 sq mi out of 858, with a population of 142,000 out of 435,000). Czechoslovakia secured all coal mines. No Czechs were left on the Polish side of the new frontier, but on the opposite side were 140,000 Poles. The decision relating to Orawa and Spisz was likewise disadvantageous to Poland, which kept 27 villages, the 44 villages awarded to Czechoslovakia had a Polish population of 45,000.

Eastern Galicia—Of 4,743,000 inhabitants of Eastern Galicia (18,245 sq mi), Ukrainians formed 52.7%, Poles 39.3% and Jews 7.2%, there was, however, a considerable Polish majority at Lwów (64% of a population of 300,000) and in some other towns. Enabled by the Austrian authorities to assume control of the whole area, the Ukrainians on Nov. 1, 1918, proclaimed at Lwów (Lviv) an independent republic of the Western Ukraine. Thereupon the local Polish population organized military formations, which succeeded in freeing the city by Nov. 22. In May 1919, after the fighting had continued for six months, the Polish army occupied the whole of the disputed province.

In March 1919 the Commission on Polish Affairs at the Paris peace conference considered the following alternatives regarding the future of Eastern Galicia: (a) a Polish mandate over the whole territory for 25 years, after which its fate was to be settled by

plebiscite; (b) partition between Poland and a Ukrainian state. There were alternative demarcation lines in connection with these schemes. Line A (see fig. 3), to run east of Przemyśl, if the whole territory were to be entrusted to Poland under a mandate, and line B which would leave Lwów and the Drohobycz oil fields to Poland in the event of the creation of a Ukrainian state. On June 25 the Supreme council accepted line A and authorized Poland to occupy the whole area, on Nov. 21, it approved the draft of an autonomous statute for the area with a 25-year mandate, on Dec. 22 1919, giving satisfaction to Polish demands, the Su-

FIG. 3—POLAND'S FRONTIERS, 1919-51 (SEE TEXT FOR EXPLANATION)

preme council rescinded its previous decision and allowed Poland to incorporate the whole area (see also GALICIA).

The Soviet Frontier—Under the terms of the armistice of Nov. 11, 1918, the German armies had to evacuate western Russia and Poland. As the Germans withdrew, the Soviet army was advancing westward. In Nov. 1918 it was still on the Dnieper, but by Feb. 1919 had moved forward to the Bug. "Militant international Bolshevism urgently required contact with revolutionary Germany, and this could only be won over the body of Poland," says Sir Bernard Pares in his *History of Russia* (Alfred A. Knopf Inc. and Jonathan Cape Limited, publishers), thus succinctly indicating the origin of the Polish-Soviet war. The Soviet government hoped, of course, that the Polish workers and peasants would greet its armies as liberators, and was greatly dismayed when they did not. (See also RUSSO-POLISH CAMPAIGN.)

A counteroffensive launched by the Polish army under Pilsudski brought the Polish-Soviet front, by the end of 1919, along the river Bereznia in Byelorussia, and in the Ukraine Novograd-Volynsk, Starokonstantinov and Bar were in Polish hands. Although in no haste to decide on Poland's eastern frontiers, the Supreme council, on Dec. 8, 1919, authorized Poland to organize a regular administration under a temporary line of demarcation "on the territories of the former Russian empire", i.e., not encroaching upon the formerly Austrian territory of Galicia. The declaration of Dec. 8 stated explicitly that the line fixed was a provisional minimum frontier, without prejudice to later terms which might be designed to fix the final eastern frontier of Poland.

On Jan. 28, 1920, Nicolai Lenin, Georgy Chuchernin and Lev Trotsky handed a peace proposal to the Polish government suggesting the actual front as the armistice line. Pilsudski doubted the sincerity of this offer because he had information that the Soviet command was concentrating new divisions on the front and Trotsky himself, in a letter to three prominent French Communists, had written shortly before: "When we have finished with Denikin, we are going to attack the Poles" (*Internationale Com-*

munste, Dec. 15, 1919). When, however, on March 27, 1920 the Polish government decided to open negotiations the Soviet government's rejection of Borisov, near the front, as a suggested meeting place confirmed Pilsudski's suspicion of a threatened Soviet offensive. On April 22, 1920, he accordingly signed a treaty of alliance with Simeon Petyura head of a Ukrainian government at Kamieniec Podolski (Kamenets-Podolski), and three days later a Polish offensive started in the Ukraine. On May 7 the Poles occupied Kiev, but on June 8 the Soviet cavalry under Simeon (later Marshal) Budenny broke through the Polish line southwest of Kiev, and on July 7 Mikhail (later Marshal) Tukhachevsky attacked north of Borisov. The military situation of Poland became critical. On July 10 Wladyslaw Grabski, the premier, went to Spa where the Supreme council was assembled to ask for immediate help in the shape of war supplies. With the assent of representatives of France and Italy, Lloyd George undertook to act as mediator. He suggested an armistice along the line of Dec. 8, 1919, in Eastern Galicia the armies were to stand on the line reached on the date of the armistice. Grabski agreed, and on July 11 Lord Curzon, the British foreign secretary, suggested an armistice to Moscow and the Polish army's withdrawal to the line of Dec. 8, 1919, and in Eastern Galicia to the line A (see above), an obvious discrepancy with the agreement reached the previous day. Thus was born the "Curzon line."

Meanwhile the situation on the front gradually changed. By mid-August Pilsudski's counteroffensive brought a decisive victory. Poland was saved, but not only Poland. "By attacking Poland," said Lenin in Moscow on Oct. 8, 1920, "we are attacking also the Allies. By destroying the Polish army we are destroying the Versailles settlement." A Soviet-sponsored government for "liberated" Poland, headed by Feliks Dzierzynski, Julian Marchlewski and Feliks Kon, which had already established itself at Bialystok, had to flee back to Moscow. A Polish-Soviet peace treaty, concluded on March 18, 1921, at Riga, added to Poland an area of 51,762 sq. mi. east of the line of Dec. 8, 1919.

The Wilno Dispute—During the advance of their armies westward, the Soviet government "ceded" Wilno (Vilnius) to Lithuania by a peace treaty signed on July 12, 1920. The city was evacuated by the Russians during their general retreat following the Polish victory and on Aug. 26 was entered by Lithuanian troops. The Poles appealed to the League of Nations, and a partial armistice was signed at Suwalki on Oct. 7. Pilsudski was strongly inclined toward a federal solution of the dispute, with Wilno and its region providing an independent link between Poland and Lithuania. Gen. Lucjan Zeligowski accordingly occupied Wilno on Oct. 9 and set up a local government. Pilsudski's scheme, however, was incompatible with the prevailing temper of the Poles and Lithuanians. On Feb. 20, 1922, therefore, the democratically elected regional assembly of 106 members voted the incorporation of the whole province in the Polish republic, 96 members voted for the incorporation, 6 abstained and 4 were absent. It remained only to obtain the approval of the principal Allied Powers. The Soviet government had declared in the Riga treaty its disinterestedness in the Polish-Lithuanian dispute. The council of the League of Nations was no longer interested and on Feb. 3, 1923, adopted a final resolution fixing the Polish-Lithuanian line of demarcation. On March 15, 1923, the Conference of Ambassadors, requested by both the Polish and Lithuanian governments to use their right to fix the frontier, recognized the demarcation line of Feb. 3 as the final frontier between the two states. (See also VILNIUS.)

By the same decision the Conference of Ambassadors recognized as final the Polish-Soviet frontier fixed by the treaty of Riga. On April 5, 1923, both Polish-Soviet and Polish-Lithuanian frontiers were recognized by the government of the United States. The long series of territorial disputes which handicapped Poland's foreign policy and its internal reconstruction was definitely settled, both legally and in fact. The new Poland had a total area of 150,052 sq. mi. with an approximate population of 27,200,000 (K. SM.)

Constitution and Internal Affairs, to 1925.—Under the constitution of March 17, 1921, Poland was a republic. The legis-

lative power was vested in a *sejm* and a senate, which were summoned adjourned and dissolved, but not without their own consent, by the president. The *sejm* was composed of paid members elected for five years, upon a system of proportional representation. Suffrage was universal, all who enjoyed full civic rights and who were over 21 being qualified to vote, soldiers on active service were excluded. Citizens over 25 were eligible for election to the *sejm*, members of the civil service could not be elected for the district in which they held office. The minimum age for voting in senatorial elections was 30, while no one under 40 was eligible for election. Bills went to the senate after being passed by the *sejm*, and if no objection was raised within 30 days the bill became law. Taxes and customs duties could be established only by law and a supreme board of control superintended the management of state finance. The executive power was exercised by the president and a council of ministers who were responsible for his official actions. He was elected for seven years by the national assembly, that is, the *sejm* and senate acting together.

For purposes of administration Poland was divided into 16 palatinates, which again were subdivided into districts and urban and rural communes. The palatine or the *wojewoda* represented the executive government in the palatinate, the *starosta* in the district. Local legislation was to be exercised by *sejmiki* in the palatinates and by district councils in the districts. Economic autonomy was established by means of chambers of agriculture, commerce, industry, etc., judicial control over the whole administration was vested in a supreme administrative tribunal.

Poland was reconstructed out of provinces of three empires in which widely different systems of law were operative. A codifying commission began to work out a body of uniform codes of law for the whole republic, in the meantime, Russian, German and Austrian codes remained in force in the different parts of the country. Gradually many domains of legal relations were covered by parliamentary legislation and, after 1926, by presidential decrees. A supreme court of justice in Warsaw was established at an early date, but it was not until 1928 that the country found itself in possession of a unified judicial organization and a uniform code of judicial procedure. Judges were nominated by the president and irremovable except by judicial decision. Justices of the peace were locally elected by the people. Over property in land, forests and mineral wealth, however, a certain amount of state control was extended by special provisions of the constitution. State protection was given to labour, and insurance against unemployment, illness and accident was guaranteed. The exercise of religion was free, as far as it was in accordance with the law. The Roman Catholic religion the predominant denomination of the country, was placed by the constitution in a privileged position.

The constituent *sejm* had 13 political parties, as well as two independent members, and it was difficult to ensure a stable government. The resignation of Paderewski (Nov. 1919) was followed by a succession of quickly changing cabinets, always based on unstable coalitions—chiefly between the Peasant centre and either the Nationalist right or the mainly Socialist left. A coalition government of national defense under the peasant leader Wincenty Witos, with Ignacy Daszynski, the Socialist leader, as deputy premier, succeeded at a critical moment in rousing the country to resist the Bolshevik invasion.

Toward the end of 1922 the prolonged legislative period of the constituent assembly came to an end. An electoral law was passed on July 28, and in November elections for the upper and lower house of the first regular *sejm* were held. They ended by distributing power in the chamber between the Nationalists (161), the Peasant groups (124) and the Party of Labour (18), the Socialists obtained only 41 seats, but the national minorities, by organizing a bloc for electorating purposes, got 81 (of whom 35 were Jews) and accordingly, in spite of the large abstention of the Ukrainian element from the elections, became an important and occasionally a decisive factor in the parliamentary system.

The first business of the two houses of the new parliament was jointly to elect a president of the republic. Marshal Pilsudski refused to stand. The parties of the left, supported by the national minorities and the Witos Peasant party, secured the election

of Gabriel Narutowicz, a friend of Pilsudski, who had acted as minister of foreign affairs in several cabinets. Polish nationalism was intensified by the election of a president through the votes of the national minorities, and on Dec. 16 a fanatic assassin named Narutowicz. The new president was Stanislaw Wojciechowski, a former Socialist and father of the Polish co-operative movement. Gen. Wladyslaw Sikorski became premier.

Poland's position in the early part of 1923 was still very unsettled. The Polish mark, a provisional currency, was affected by the collapse of the German mark. A government formed in the spring by Witos, on the basis of an alliance between the Peasant party and the National party, had to struggle against the resolute opposition of the left and the national minorities, the government proved unable to cope with the continued, disastrous fall of the mark and there was serious unrest in the country, culminating in riots at Cracow on Nov. 6, the government was obliged to resign on Dec. 11. It was followed by a nonparty one under Wladyslaw Grabski, who, as prime minister and minister of finance, made financial reform his principal task. The political parties now at last agreed to subordinate all other problems to those of financial reconstruction. On Jan. 3, 1924, Grabski's government was granted emergency powers for the purpose. Fulfilling partly the recommendations of a British financial adviser, Edward Hilton Young (later Lord Kennet), Grabski strenuously reorganized the financial system of the country. A Bank of Poland was once more created on a basis of private subscription. The budget was balanced by Draconian reductions in expenditure, the printing of paper money stopped, the currency became stabilized at the rate of exchange which it had reached (1,800,000 marks to the gold franc), and finally a new currency unit, the zloty, was introduced and declared equal to the gold franc. The drastic manner in which this financial reform was accomplished inevitably brought about its revenge. The too-high level at which the value of the new currency had been fixed caused a period of heavy economic depression.

On Feb. 10, 1925, a concordat with the Holy See was signed. The Catholic Church was granted absolute freedom of execution of its authority and jurisdiction in Poland, the assistance and support of the state being assured it in this respect. The state's interests in connection with nominations for the higher ecclesiastical posts were adequately protected. In religious education, the competencies of church and state were exactly defined. The division of Poland into ecclesiastical provinces was carried out in such a way that no portion of Polish territory remained subject to the jurisdiction of a bishop residing outside the borders of the state. An autocephalous Orthodox Church also established in Poland received the blessing of the synod and of the ecumenical patriarchate in Constantinople on Nov. 11, 1924. The Protestant Church in Poland was likewise placed beyond reach of political influences from abroad.

Alliances and Security.—In the first years of Polish independence, France's support was Poland's greatest asset. At the end of 1920 the French premier, Alexandre Millerand, invited Pilsudski to visit Paris in his capacity of head of state. As a result of discussions during this visit a political agreement was signed in Paris on Feb. 19, 1921, by Aristide Briand and Prince Eustachy Sapieha, ministers of foreign affairs. It provided that the two governments should take concerted measures for the defense of their territory and the protection of their legitimate interests if either or both of the contracting states, in spite of sincere peaceful intentions, should be attacked without provocation. On March 3, 1921, a treaty of alliance with Rumania was signed at Bucharest by Sapieha and Take Ionescu. On March 26, 1926, the Polish-Rumanian alliance was renewed. It stipulated that the two countries should pledge themselves to defend their territorial integrity and political independence against any outside aggression.

A definite alliance between Poland and the Baltic states was attempted on March 17, 1922, when a political treaty was signed in Warsaw by the foreign ministers of Poland, Finland, Estonia and Latvia. It stipulated that in the event of aggression against one of the contracting parties all four governments should cooperate on measures to be taken. On May 12, however, the

Finnish parliament refused to ratify the treaty.

By the end of 1921 Polish-Czechoslovakian relations became cordial enough, and Konstanty Skirmunt, the foreign minister, paid an official visit to Prague. On Nov. 6 he signed with Eduard Benes a political convention by which the two governments agreed to act in concert for the application of the treaties which they had signed in common. There was some talk at that time of closer collaboration between Poland and the Little Entente, but the latter's aim, directed against Hungarian revisionism, was from the Polish point of view too limited. In June 1923 Marian Seyda, the Polish foreign minister, suggested the transformation of the Little Entente into a quadruple alliance, providing all the members with a collective guarantee of security, but this idea met with a cool reception in Prague. Count Alexander Skrzynski, Seyda's successor at the foreign office, was less ambitious. Benes paid a visit to Warsaw in April 1925 and a Polish-Czechoslovakian treaty of conciliation and arbitration was concluded.

Great Britain's rejection of the so-called Geneva protocol and of the principle of collective security alarmed Poland, as did the German proposals to France, which treated separately the problems of Germany's western and eastern frontiers. The Polish thesis was that European security was indivisible. A not too satisfactory compromise formula was found. The treaties initiated at Locarno (q.v.) on Oct. 16, 1925, and signed in London on Dec. 1 included two agreements concerning Poland: a Polish-German arbitration treaty and a Franco-Polish treaty of guarantee. The former provided for the peaceful settlement of disputes, in the latter France guaranteed the Polish frontier with Germany. Polish opinion was not easily reconciled to the idea of the Locarno treaties. They were accepted, but for the first time the Poles felt that they were abandoned by France.

The Second Coalition Government.—Soon after the breakdown of his financial policy Grabski resigned. He remained in power for 23 months, a record in Polish parliamentary history. On Nov. 20, 1925, Skrzynski formed a coalition cabinet, the second of this kind since the restoration of the state. This time the frontiers were secure, but the country was again in danger. The treasury was almost empty, the shortage of private capital was acute, unemployment was rife and the zloty continued to fall. Another storm centre of embittered dispute was the question of reinstating Marshal Pilsudski in the position of commander in chief of the army. He had resigned the office of chief of staff in May 1923 when a government of the Nationalist-Peasant coalition was formed.

In foreign affairs the Skrzynski administration was under the shadow of a growing feeling of international insecurity for Poland. When, a month after the ratification of the Locarno agreements, the League of Nations proceeded to elect Germany a permanent member of the council, Skrzynski claimed a permanent seat for Poland as well. It was not till after a good deal of dramatic friction in the League that a solution was found, Germany getting a permanent and Poland a so-called quasi-permanent seat in the council.

Pilsudski's Rule, 1926-35.—Meanwhile internal dissensions intensified while the conclusion of a new Soviet-German treaty in Berlin (March 1926) increased the general nervousness. Pilsudski, in his retreat at Sulejowek, was looked up to by large masses of the people as the only man who could secure a better future for the country. His adherents and opponents formed two opposing camps in the army. In parliament, the right, since the days of his provisional presidency, had used every legislative device to limit his power and influence. Now, in the dispute over his command, the right desired to frame the Army Organization bill in such a way as to bring the army under the direct control of parliament, while Pilsudski insisted on complete independence of the commander in chief.

Matters came to a crisis when, because of the dissensions over the budget, the Socialist ministers left the cabinet, and Skrzynski himself resigned in consequence. After a prolonged period of negotiations Witos succeeded in forming a ministry. Rumours were current that he meant to rely exclusively upon the support of the right and to settle the question of the commandship in the

sense demanded by the Nationalists. Thereupon, on May 12, Pilsudski suddenly entered Warsaw at the head of troops. The government proclaimed him a rebel. The concentration of government troops in Warsaw, however, was hampered by a strong strike movement in the country, chiefly among the railwaymen, and after two days of heavy fighting in the streets of Warsaw, Pilsudski was master of the capital. The government resigned and the president of the republic abdicated. Macej Rataj, the speaker of the *sejm*, became acting head of the state, in accordance with the terms of the constitution. A provisional cabinet under Kazimierz Bartel was appointed, pending the election of a new president. When the two chambers met on May 31 for the presidential election, there resulted a majority of 292 to 193 in favour of Pilsudski. He, however, refused the office in favour of his nominee, Ignacy Moscicki, a scientist not formerly engaged in politics, who was duly elected on June 1 by 281 votes to 200. Pilsudski himself became minister of war and a few months later officially assumed premiership in the cabinet.

Pilsudski met with little opposition when on Aug. 2, 1926, he proceeded to reform the constitution in the sense of limiting the powers of parliament with respect to the budget. If within a period of five months the budget was not passed, the finance bill acquired the force of law. Another provision gave the president the right to dissolve the parliament on a unanimous proposal of the government, the new elections taking place within 90 days.

A year and a half after Marshal Pilsudski's coup d'état, a new parliamentary election became due in Poland. He had left the outward structure of the parliamentary system intact. The practical impotence, however, to which his rule reduced the sometime all-powerful parliamentary parties had a profound effect on them. The largest groups began to disintegrate, and when the elections approached as many as 35 different factions appeared in the field with lists of candidates of their own. This "pulverization of the party system" was the result of splits in the larger groups on the one issue that remained dominant under the circumstances, viz., the question for Pilsudski or against him. In the midst of this reshuffling of all former groupings, the government created a nonparty bloc of its supporters of various shades of opinion. From the elections held on March 4 and 11, 1928, only the Socialists emerged with a substantial increase in the number of their seats (64 as against 41), the other parties which had once been strong factors—the Peasant, the Party of Labour, the Christian Democratic and the Nationalist—dwindled from 230 to 150 seats. The government bloc obtained 135 seats. (R. Dy; X.)

The opposition, however, remained strong, and a normal co-operation of the parliament with Pilsudski proved impossible. In the autumn of 1930 the growing tension resulted in the arrest of some of the party leaders, who were imprisoned at Brzesk and treated there very badly. New elections held on Nov. 16 and 23 gave the government bloc an absolute majority of 247 seats in a *sejm* of 444, the National Democrats winning 63 seats, the Centre-Left coalition 92 and the national minorities 33.

The Constitution of 1935.—After his electoral success Pilsudski said that the principal task of the new parliament was the revision of the constitution. A draft was introduced to the *sejm* on Dec. 20, 1933, it was passed by it on Jan. 26, 1934, and by the senate on Jan. 18, 1935. On March 23, 1935, the new constitution was definitely adopted by the *sejm* by 260 votes to 139, it became law on April 23.

It was based on the following principles: the state being considered as the "common good" of all the citizens, the executive became considerably strengthened at the expense of the legislature; the president appointed and dismissed the prime minister and the commander of the army, could dissolve the *sejm* and was responsible to none, the six "organs of the state"—government, *sejm*, senate, army, courts of justice and court of supervision—were accordingly under the president's control, the powers of the legislature were strictly limited and the number of its members reduced to 208 in the lower and 96 in the upper house, one-third of the latter being nominated by the president.

Foreign Relations.—During the first six years of Pilsudski's regime, August Zaleski being minister of foreign affairs, Poland's

policy was chiefly based upon the League of Nations and the close alliance with France. Poland, which had proposed to the League's assembly of 1927 a resolution outlawing wars of aggression, not only signed the Kellogg pact of the next year but even anticipated its realization by a special agreement with Soviet Russia in 1929. On July 25, 1932, that protocol was developed into a pact of nonaggression. At the disarmament conference of the same year the Polish delegation had played an active part, submitting an elaborate plan of "moral disarmament", but it became obvious that the idea of collective security had failed, and Poland sought better guarantees in bilateral agreements with its neighbours.

After 1932 this method was developed by the new minister of foreign affairs, Col. Jozef Beck, formerly Pilsudski's *chef de cabinet*, and found its strongest expression in another ten-year non-aggression pact, concluded on Jan. 26, 1934, with Germany. There was of course a reservation that the new treaty was not to affect Poland's previous engagements, particularly its alliance with France. Nevertheless, it seemed to involve a change in Poland's general attitude. Seeing that nobody in Europe was prepared to fight the new Adolf Hitler regime, Pilsudski found it necessary to accept a direct understanding with Poland's western neighbour also, holding the balance between the Soviet Union and Germany.

Moscicki and Smigly-Rydz.—After Pilsudski's death on May 12, 1935, the form of government which he had established continued without much change. The voting regulations, as applied at the elections of Sept. 8 and 15, 1935, without having been defined in the new constitution itself, again raised much discontent, but attempts were started to come to some co-operation with various groups of the opposition. The government bloc was dissolved and replaced by a Camp of National Unity. Both President Moscicki, who had been re-elected in 1933 for another seven-year period, and Marshal Edward Smigly-Rydz, Pilsudski's successor as commander of the army (who was styled "the second person" in the republic), exercised their authority with moderation and in a conciliatory spirit. Such an appeal to internal unity was indeed indispensable in face of the increasing danger of the international situation.

That danger resulted from the policy adopted by Germany. After the annexation of Austria and the destruction of Czechoslovakia, it was clear that Hitler wanted to isolate the eastern European states so as to be able to attack them one by one. Soon after Munich, when Poland had seized the opportunity to claim the contested Teschen territory (see above), there began a new tension with Germany. Yet on Jan. 30, 1939, Hitler reaffirmed the importance of the German-Polish nonaggression pact as a contribution to the peace of Europe, but he had already decided to annex the Free City of Danzig, and on March 27 he officially requested the Polish government to accept that solution as well as the construction of an extraterritorial motor road through the Polish province of Pomorze. Touched in its vital interest and realizing that it was a first challenge against its independence, Poland refused, making counterproposals which were never taken into serious consideration. As soon as Poland had exchanged with Great Britain reciprocal guarantees of independence and integrity, Hitler took it as a pretext to denounce, in his speech of April 28, the nonaggression pact of 1934.

During the next four months he tried to provoke Poland by various incidents in Danzig and started a propaganda campaign against an alleged ill treatment of the German minorities in Poland. But it was not until Germany had concluded, on Aug. 23, a new partition treaty with the U.S.S.R. that he finally decided to attack Poland. Two days later a close alliance was signed between Poland and Great Britain which made it absolutely clear that Great Britain, as well as France, would support its ally in case of war, but in spite of a patent conciliatory effort made by British diplomacy and proposals of a peaceful settlement put forward by various powers and accepted by Poland, Germany invaded Poland on Sept. 1, 1939.

WORLD WAR II

Poland, which had postponed the general mobilization to the last moment, was unable to stand against the overwhelming Ger-

man forces, the long open frontier stretching from East Prussia to Slovakia being already occupied by German troops, nevertheless, it made a courageous resistance in the centre of the country until Sept. 17, when the Soviet army invaded its territory from the east under the pretext that the Polish state was no more in existence. Even then in various regions desperate fighting was continued, and Warsaw, although severely bombed, like so many other open places, defended itself heroically until Sept. 27. The next day a second German-Russian treaty was signed in Moscow by Joachim von Ribbentrop and Vyacheslav Molotov redistributing the spoils; the eastern provinces, including purely Polish territories were incorporated in the Soviet republics of Byelorussia and the Ukraine, the western part was left within the German sphere of influence.

Before leaving Polish territory, President Moscicki resigned and designated Władysław Raczkiewicz as his successor. The new president appointed a new government, the former having been interned in Rumania. General Sikorski became prime minister, Zaleski minister of foreign affairs, and both president and government were established at Angers, Fr. The Polish army was also reconstituted in France to fight with the Allies, while some Polish warships, having escaped, joined the British navy.

Sikorski also became the commander in chief of the reorganized Polish army. This was possible because part of the army had passed into Hungary and Rumania and succeeded in assembling in France, where its ranks were swelled by mobilization among the prewar Polish emigrants in that country. The Polish army, numbering nearly 100,000, was ready by the spring of 1940. A Polish brigade fought in the Norwegian expedition of the Allies, especially in the battle of Narvik, and the Poles joined also in the defense of France.

The collapse of France was likewise a heavy blow for Poland. In spite of fresh losses and the capitulation of one of the Allies, the Polish army did not even then dream of ceasing to fight. About 15,000 who had heroically protected the retreat of one of the French armies had to cross into Switzerland, where they were interned. A part of the Polish army was transported to Great Britain, where, at the end of June 1940, the Polish government together with the president transferred itself. The Polish army began increasingly to distinguish themselves, acting with the royal air force, and simultaneously Polish divisions, dispersed through the world as of old in the Napoleonic wars, appeared in Palestine and on the Egyptian-Libyan battlefield. (See also WORLD WAR II)

Germany divided the conquered Polish land into two zones. The provinces that had been ruled by Prussia from the Vienna settlement to 1918 and also part of central Poland with Łódź (renamed Litzmannstadt) and Płock were incorporated into the reich on Oct. 19, 1939. All the incorporated lands were destined for complete germanization. The remaining territory between the new German frontier and the Molotov-Ribbentrop line was organized as a *General Gouvernement*. It was divided into four districts: Warsaw, Lublin, Radom and Cracow. In Aug. 1941, shortly after the German attack on the Soviet Union, the province of Białystok was incorporated into Germany, while Eastern Galicia, with Lwów, was added as the fifth district to the *General Gouvernement*. This territory was to be used mainly as a reserve pool of labour. All Polish elements were submerged, and it became for a time, as Hans Frank, the governor general, described it, "an intellectual desert."

Such a policy was countered by immediate reactions in the community. The professors of Cracow university, who were invited to co-operate in the administration of the *General Gouvernement*, preferred internment and death to assisting the Germans in any way. Polish property was confiscated, and continual deportations of workers into the reich enabled the Germans to solve their growing problem of manpower. Concentration camps were established, and Oswiecim (Auschwitz) became especially notorious for the deliberate and systematic torture and murder of its inmates. Unknown numbers of Poles perished there and it became the grave of a great part of the 3,000,000 Polish Jews. In opposition to this terror, the Poles organized a powerful underground movement

which continued the cultural and social life of the people in secret schools, social services and an active press. A secret home army grew to considerable strength and carried out operations against German communications and institutions. The administration of the underground organization took its orders from the Polish government in London.

Far more complicated was the position of the Poles in the eastern areas occupied by the Soviet Union from Sept. 17, 1939, to late June 1941. There the problem was Ukrainian as well as Polish. All political leaders, Polish and Ukrainian, together with the bulk of the educated classes were deported, but less open violence and more subtlety were used than in the German zone and the annexation to the Soviet Union was effected only after a so-called plebiscite which was claimed to have justified the act. The growing terror under the Soviet police was checked by the German invasion, which made the position of Poles in the U.S.S.R. easier but offered a difficult problem to the Polish government in London. The great mass of the Poles abroad continued to regard the Italians, who had helped many of them to escape, as their friends, and to mistrust Soviet intentions toward their country. But political and military reasons led Sikorski to make an agreement with the U.S.S.R. The terms of this agreement, signed in London on July 30, 1941, ended the state of war between the two countries and raised hopes of an ultimate restoration of Poland in its former boundaries, but it was more immediately important in enabling Gen. Władysław Anders to organize a Polish army in the Soviet Union. Sikorski visited Moscow and on Dec. 4 signed with Joseph Stalin a Polish-Soviet declaration of mutual assistance and collaboration. Stalin agreed that the Polish army in the U.S.S.R., originally projected as two divisions, should be increased to a strength of six divisions. About 75,000 of the men already recruited by Anders were allowed to leave for the middle east in March and Aug. 1942. Unfortunately, as the danger of defeat by the Germans was averted, the Soviet authorities began to adopt a more aggressive attitude to Polish claims.

It was possible to form a Polish army in the U.S.S.R. since there were more than 200,000 Polish prisoners of war taken by the Russians in Sept. 1939 and hundreds of thousands of Polish nationals deported. Securing a corps of officers for the new army offered a more serious problem. In Oct. 1939 about 14,300 Polish officers were segregated by the Soviet authorities into three prison camps at Ostashkov, Kozelsk and Starobelsk. The Polish authorities in the Soviet Union and the Polish underground in the homeland failed to find any trace of the missing officers after April 1940, although it was suggested by the Soviet government that they had been exchanged with their German allies in 1940. When in April 1943 mass graves were discovered in Katyn wood near Smolensk, containing the bodies of the men who had been imprisoned in the Kozelsk camp, the Germans accused the Russians of having murdered them. The Soviet government refused an investigation by an International Red Cross commission suggested by Sikorski and, on April 25, 1943, broke off diplomatic relations with the Polish government.

Sikorski was killed in an aeroplane accident at Gibraltar on July 4, 1943, and was succeeded as prime minister by Stanisław Mikolajczyk, the leader of the Peasant party, and as commander in chief by Gen. Kazimierz Sosnkowski. As their military position improved and they began to reoccupy Polish territory, the Soviet authorities' new policy became more anti-Polish. They revived their claim to the eastern provinces and began to protect a group of Poles who were prepared to accept this claim. This group was joined by a number of Polish Communists including Bolesław Bierut and came to be known as the "Lublin committee" and then to be a provisional Polish government. All attempts by the London government to co-operate with or oppose them came to nothing, and the Soviet authorities started a great campaign of propaganda to discredit the legal Polish government in London.

Another move was to smuggle Communists into German-occupied Poland ostensibly to help but really to displace the leaders of the underground movement. These leaders continued to carry on their heroic struggle in co-operation with the government in London. As at the end of July 1944 the Soviet army

reached the Vistula and neared Warsaw the underground was requested by broadcasts from Moscow to support it, and Gen. Tadeusz Bor-Komorowski, commander of the home army, under orders from the military headquarters in London, started an open struggle in Warsaw on Aug. 1, 1944. Despite the efforts of the western Allies to send arms and supplies by air, the sacrifice was made useless by the inactivity of the Soviet armies, which refused to send any support. The struggle continued for 63 days, after which further resistance was impossible.

Even before this tragic event the Soviet generals, as they advanced into Poland, had been disarming and deporting members of the home army which was helping them. Now that the main army of the underground had perished, the task of the Soviet political leaders was made easier. While the Polish forces in the west continued to fight the battle with their Allies on land, sea and in the air, especially in the great advance through Italy, and, after June 6, 1944, in northern France, Belgium and the Netherlands, the Russians did all they could to discredit the Poles fighting against the common enemy in Poland and the government in London to which they gave their allegiance.

The fate of Poland was now taken over by the Great Powers, which at the Yalta conference in Feb. 1945 tried to settle the difficult questions which had arisen. As a result, the Soviet Union was able to obtain recognition of the Lublin committee. Both the Polish government and the underground movement sank out of sight, and when World War II came to an end a Polish "people's republic" was established. (A. B. Bo.)

THE "PEOPLE'S REPUBLIC"

Pres. Franklin D. Roosevelt, Winston Churchill and Marshal Stalin decided at Yalta, on Feb. 11, 1945, that a "Polish provisional government of national unity" should be created; i.e., that the Soviet-sponsored government formed at Lublin on Dec. 31, 1944, should be reorganized to include "other Polish democratic leaders from Poland and from abroad." The three powers jointly engaged that free and unfettered elections on the basis of universal suffrage and secret ballot should be held as soon as possible. After four months of diplomatic discussion among Moscow, London and Washington concerning the exact interpretation of the Yalta decision, a Polish round-table conference met in Moscow on June 17, 1945, to discuss the formation of a Polish government. Among leaders from within Poland and from abroad attending the conference were Mikolajczyk (who had until Nov. 24, 1944, been premier of the Polish government in London) and Wladyslaw Kiernski, both sent to Moscow by the aged Witos and representing the Polish Peasant party. On June 28, 1945, the composition of the government was announced. It showed that the Soviet interpretation of the Yalta declaration had prevailed: of the 21 members of the cabinet only 5 were newcomers, the most important being Mikolajczyk, who became second deputy premier, 16 ministers were former members of the Lublin government, including Edward Osobka-Morawski, leader of a split Socialist group who remained premier. Bierut, who from July 22, 1944, had been chairman of the presidium of the so-called Polish national home council, became provisional president of the republic. Without waiting for the formation of the provisional government of "national unity," Stalin and Osobka-Morawski on April 21, 1945, signed in Moscow a Soviet-Polish treaty of friendship, mutual assistance and postwar collaboration. On July 5 the British and the U.S. governments recognized the new Warsaw government and withdrew recognition from the London government composed of representatives of the National, Christian Democratic and Socialist parties and presided over by Tomasz Arciszewski, a senior Socialist leader who until July 1944 was the chairman of the underground Council of National Unity in Warsaw.

Only on Nov. 13, 1946, under pressure of the British and the U.S. governments, Bierut signed a decree fixing Jan. 19, 1947, as the date for the Polish elections. The official figures stated that 11,413,618 voted out of 12,701,056 qualified electors, 9,003,682 (80.8%) voted for the Communist-controlled Democratic bloc and 1,154,847 for the Polish Peasant party. Out of 444 seats in the *sejm* the Democratic bloc secured 382 (118 Communists, 108

Communist-controlled Peasants, 118 left-wing Socialists and 38 Democrats), the Polish Peasant party 28, the proregime Party of Labour (allegedly Christian Democratic) 17, the proregime "New Liberation" peasant group 13 and the Independents 4. It was officially stated in both the United States and Great Britain that the elections were neither free nor fair. The new *sejm* on Feb. 5 elected Bierut president of the republic, and two days later he appointed a new government headed by Jozef Cyrankiewicz, a left-wing Socialist.

A striking political development took place within the ranks of the Polish Workers' (Communist) party on Sept. 3, 1948 when it was announced that Wladyslaw Gomolka, its secretary-general and first deputy premier had been accused of "rightist and nationalist deviation" and been obliged to recant and to resign from both offices. Although the leadership of the split Polish Socialist party was already purged, there was still resistance against a proposed merger with the Communist party which, for the former, was equal to dissolution. Nevertheless, the merger congress assembled in Warsaw from Dec. 15 to Dec. 22, 1948. The new party was called the Polish United Workers' party, and Bierut became its chairman. Among the 11 members of the Politburo were three former Socialists, including Cyrankiewicz, Mikolajczyk, accused on Oct. 12, 1947, of being "an ally of foreign imperialists," escaped and arrived in London on Nov. 3, 1947. On Nov. 30, 1949, the rump of the Polish Peasant party and the two Communist-controlled peasant groups were fused under the name of United Peasant party. In July 1950 the Party of Labour was absorbed into the Democratic party.

The new constitution passed unanimously by the *sejm* on July 22, 1952, was modelled on the Stalin constitution of 1936. The supreme organ of state authority was the council of state (in the U.S.S.R. the presidium of the supreme soviet) elected by the *sejm* and composed of a chairman, four deputy chairmen, a secretary and nine members. The supreme organ of state administration was the council of ministers appointed by and responsible to the *sejm*, or to the council of state when the *sejm* was not in session.

The electoral law adopted by the *sejm* on Aug. 1 accorded the franchise to all citizens of 18 years, including members of the armed forces; citizens of 21 years were eligible for election. There was one deputy for every 60,000 inhabitants. The 425 members of the new *sejm* were elected on Oct. 26, 1952, in Soviet fashion, i.e., there was only one list of official candidates in each of 67 constituencies and 99.8% of valid votes were allegedly cast for them.

The New Frontiers.—On Aug. 16, 1945, Molotov and Osobka-Morawski signed in Moscow a treaty demarcating the Soviet-Polish frontier. This demarcation, more or less identical with the so-called Curzon line, restored to Poland the province of Bialystok in the north and a smaller area in the south including Przemysl, which the Molotov-Ribbentrop line had assigned to the U.S.S.R. In a small exchange of territory on Feb. 15, 1951, the U.S.S.R. acquired a strip of land of 185 sq mi. south of Hrubieszow containing part of the railway system feeding the strategic centre of Lwow, while a similar area south of Przemysl, including the town of Ustrzyki Dolne and a sector of the sub-Carpathian oil field, was returned to Poland. (See fig. 3.)

On Aug. 2, 1945, at Potsdam, Pres. Harry S. Truman, Clement Attlee

been seized by Poland in Oct. 1938, were left to Czechoslovakia.

As compared with its territory before World War II, Poland was shifted westward considerably. In the east it lost 68,667 sq mi. and in the west it gained 38,974 sq mi., its new area being 120,359 sq mi.

POLAND

At the beginning of the historical period the Poles lived between the Baltic sea and the Carpathian mountains and the Oder and Bug rivers. They were one of the western branch of the Slavonic group of peoples. The Polish nation originated from three main tribal groups, the Polanie, the Mazowszanie and the Pomorzanie. Because of their central position, the Polanie, or dwellers in the plains (*pole*, "field"), gave their name to the country, *Polska*, and to the people, *Polacy* (singular *Polak*).

The Polanie themselves were originally composed of many tribes, the most important of them being the Slezanie (now Slezacy or Silesians) who settled on both sides of the middle and upper Oder, the Kujawacy (Kujavians) who lived between Lake Goplo and the Vistula; and the Wislanie, called later Malopolanie, on both sides of the upper Vistula.

The Mazowszanie or Mazovians lived on both sides of the middle Vistula, and their Baltic neighbours to the northeast were the Lithuanians and the Prussians. The Mazurians of East Prussia were descendants of Mazovian settlers who came there in the 15th century.

The Pomorzanie or Pomeranians, as their name indicates, were living along the seacoast (*po*, "toward", *more*, "sea") between the lower Oder and lower Vistula. They formed an element of transition between the Polanie and the Polabians (*po Labé*, "along the Elbe"). The Polabians were germanized between the 10th and the 18th centuries, as were also those Pomeranians who remained outside Poland after the treaty of Torun of 1466.

Linguistically, however, two local Pomeranian dialects remained until the 20th century, the Slowince (Slowinski) and the Cassubian (Kaszubski). Slowince was spoken until World War I along the Baltic coast line between Slupsk (Stolp) and Leborg (Lauenburg). At mid-20th century Cassubian was still spoken west of Danzig in the districts of Wejherowo and Kartuszy.

Preliminary figures published after the census of Dec. 3, 1950, gave 24,976,926 as the total population of Poland, composed of 11,912,514 males and 13,064,412 females. At the time of the summarized census of Feb. 14, 1946, the total was 23,929,757. The last pre-World War II census (1931) recorded a total of 32,707,252, while an estimate for Sept. 1, 1939, stated it to be 35,339,000 (excluding the Teschen disputed territory). Both sets of figures illustrated the high rate of natural increase which distinguished Poland from its western neighbours. The actual increase between 1946 and 1950, calculated by the authorities in Warsaw to be about 2,139,000, was greater than apparent, having been obscured by two-way movements of population. The rate of increase, estimated at 1% a year even after allowing for the aftermath of World War II, was expected to bring the total population in 1960 to about 27,000,000. This would mean an average density of 220 persons per square mile (212 in 1931).

No part of Europe was more profoundly affected by the great

displacements of population which took place in and for some years after World War II. Polish citizens were deported by both occupying powers during the German-Soviet partition and by the Germans over the whole of Poland after June 1941. As the tide of war swept back across Poland in 1944 and 1945, heavy casualties were inflicted upon the local population, the Polish resistance being a mass movement.

The territories annexed by the Soviet Union had a population of about 10,768,000 in 1939; by June 30, 1949, only 1,503,800 persons of Polish nationality were transferred from Soviet territory to the new Poland. The recovered lands in the west (i.e., former territories of Germany and the Free City of Danzig) had in 1939 a total population of about 8,300,000, including 1,012,000 Poles. The 1946 census disclosed a population there of 5,022,200, including 2,075,900 Germans. By 1950, in accordance with the decisions of the Potsdam conference, all the Germans had been transferred to Germany. After this evacuation most of the population of the recovered lands was composed of autochthonous Poles, who had formed a minority in Germany and had been subjected to gradual germanization. To these indigenous inhabitants were added Poles repatriated from the Soviet Union, Poles repatriated from the west (mainly from Germany, France and Great Britain) and Poles transferred from the central parts of Poland. Central Poland (territories Polish both before 1939 and after 1945) counted more than 23,000,000 persons in 1939 but fewer than 19,000,000 in 1945.

As a result of all these displacements and territorial changes, Poland was converted from a country with large ethnographic and religious minorities into one almost entirely Polish in language and Roman Catholic in faith. The situation in 1931 is summarized in Tables I and II.

TABLE I—Population According to Language (1931 Census)

Language	Number	Percentage
Polish	21,993,400	68.9
Ukrainian*	5,122,000	10.1
Ruthenian*	1,510,000	3.8
Byelorussian	686,000	1.2
Russian	138,700	0.4
German	741,000	2.3
Yiddish and Hebrew	2,718,000	8.0
Miscellaneous†	276,000	2.8
Total	31,915,800‡	100.0

*See the source, but Ukrainian and Ruthenian are two names for the same language. †This rather high figure includes 708,000 "local" Jews. ‡Excluding about 101,500 troops in barracks. Source: *Maly Rocznik Statystyczny* (Warsaw, 1939).

TABLE II—Population According to Religion (1931 Census)

Religion	Number	Percentage
Roman Catholic		
Latin rite	20,670,100	64.8
Greek Catholic rite	3,325,900	10.4
Orthodox	3,169,500	11.8
Lutheran, Reformed, etc.	835,200	2.6
Other Christian	145,400	0.8
Jewish	3,111,000	9.8
Other non-Christian	6,800	0.0
Unclassified	45,700	0.1
Total	31,915,800‡	100.0

The loss of territories to the Soviet Union deprived Poland of the Ukrainian, Byelorussian and Lithuanian minorities as well as many Jews, who were regarded automatically as Soviet citizens and absorbed into the adjoining Soviet republics. The most terrible change, however, was brought about by the disappearance of the large Jewish minority. Scattered over the whole of Poland, but particularly numerous in the cities, nine-tenths of them speaking Yiddish, the Jews had been a characteristic feature of Poland. They numbered about 3,440,000 in 1939 but fewer than 100,000 in 1951. The Nazi racial policy, manifested at first in the creation of the Lublin reservation and then in the segregation of the Jews into ghettos in all the larger towns, resulted in the systematic extermination of more than 2,000,000 Polish Jews. The massacre of the Warsaw ghetto in 1943 and the work of the extermination camps at Oswiecim, Majdanek, Belzec, Chelmno, Sobibor and Treblinka were extreme examples of Nazi brutality.

Roughly one-third of the former Polish Jewish minority lived in territories annexed by the Soviet Union, by whom they were

generally regarded as not eligible for the option of Polish citizenship in 1945. Jews were, however, repatriated to Poland, probably half the total of 300,000 Jews who had fled or were deported to the Soviet Union in addition to those in the annexed territories were permitted to return to Poland after the war. The American Joint Distribution Committee sponsored the emigration of most of these to Palestine in 1946 and 1947. Subsequently, the Polish government's general ban on emigration was extended to the Jews also, although a few continued to receive exit permits.

Apart from the Jews, major dislocations of the population of Poland after 1939 were as follows. Poles expelled from areas incorporated in 1939 into Germany, more than 2,000,000. Poles sent to German camps and forced labour, more than 3,000,000. Poles deported to Soviet camps, 1939-40, more than 1,000,000. Ukrainians, Byelorussians and Lithuanians transferred from central Poland to the U.S.S.R., 1945-49, more than 518,000. Germans fled and repatriated from lands east of the Oder-Neisse (including 747,000 in prewar Poland), about 7,900,000.

TABLE III—Development of Major Towns, 1880-1950
(To nearest thousand)

Town	1880	1910	1921	1930	1946	1950
Warsaw	381	781	937	1,289	479	650

Gdynia	—	2	2	130	78	103

*Including troops in barracks 1915

Table III illustrates the main trends of urban population after 1880. It shows clearly the sudden development of Polish cities after 1920 with the restoration of Polish sovereignty, and especially the transformation of Gdynia from a fishing village to a port of international significance—a development which was one of the more remarkable feats of pre-1939 Poland. The vast losses borne by Warsaw during World War II, the decline of the Silesian towns and the Baltic ports and the changes in other towns appear in the figures for 1946. Those for 1950 show to what extent the losses were reversed. The population of Warsaw, reduced to 153,000 in Jan. 1945, had recovered to 650,000 by Dec. 1950 and, within wider administrative boundaries, to 760,000 by 1951, which, however, was still below the figure for 1910. The rate of rebuilding devastated Warsaw was one of the controlling factors, another was the increasing attention given to the development of heavy industry, particularly although not exclusively in Silesia and the recovered lands. An example of the last trend was the development of a new town at Nowa Huta, near Cracow, planned to house 100,000 people.

Poles Abroad—The Poles are one of the most widely dispersed of the European people. The lack of natural frontiers east and west encouraged at one period the great spread of Polish culture over a wide area but led at another to dismemberment by the neighbouring great powers, Austria, Prussia and Russia or Germany and the Soviet Union. Major European wars swept back and forth across the Polish lands and left devastation in their wake. Despite the effects of war and occupation, Poland, particularly in the fertile areas of ancient settlement in the southern provinces, felt the pressure of its own populations and provided colonists and foreign labour in most corners of the world.

Poles abroad, therefore, became divided into two categories: the autochthonous Poles inhabiting alien territory contiguous with the political frontiers of Poland and the emigrants and refugees between 1921 and 1939, the largest groups of autochthonous Poles were in eastern Germany, numbering 1,012,000 when brought under Polish control in 1945, and in the U.S.S.R., where, according to the Soviet census of 1946, there were 792,471 Poles, including 476,435 in the Ukraine and 97,948 in Byelorussia. Poles were

estimated in Lithuania at 200,000, in Latvia at 75,000 and in Rumania at 65,000 (including 50,000 in Bukovina). The three last-named territories all formed part of the U.S.S.R. by 1945. To these were added the Poles in the Polish territories incorporated by the Soviet Union. Perhaps the major part of these eastern Poles were dispersed, some were deported to the east, a part of whom succeeded in joining the Polish army which left the U.S.S.R. in 1941-42, some were repatriated in 1945. Yet others found the claim to Polish nationality discounted, and an uncertain number perished. Finally, according to the Czechoslovakian census of 1930, there were 77,300 Poles living in the disputed Teschen area, which later again became part of Czechoslovakian territory, according to Polish official estimates these numbered 170,000. The exact number of autochthonous Poles was not accepted by all the states involved, estimates are complicated by the prolonged intermingling of cultures and tongues, by intermarriage, by rival political propaganda and forced assimilation and by the changing frontiers.

The largest number of emigrants before 1939 settled in the Americas. By 1951 they included about 180,000 in Canada (mostly in Ontario and the prairie provinces), 300,000 in Brazil (mostly in Paraná), 70,000 in Argentina and 18,000 in Paraguay, but the greatest single group was in the United States, where there were probably 4,500,000 persons of Polish descent. Official statistics for 1940 revealed that there were 2,416,320 persons in the United States whose mother tongue was Polish, the largest non-English-speaking group after the German- and Italian-speakers. Chicago was the largest Polish centre, with about 500,000 Poles, Detroit had 200,000, Buffalo, Cleveland and Milwaukee each more than 100,000 and New York city, Pittsburgh and Philadelphia each 50,000. Poles engaged in agriculture, about one-fifth of the total, were spread across the states of Michigan, Wisconsin, Missouri, North and South Dakota and Texas. Immigration was at its greatest up to about 1930, before the quota systems and the world economic depression had everywhere dried up the streams of settlers to the new world. Between 1921 and 1930 more than 200,000 Poles entered the United States. Steady assimilation ensued, of course, but these U.S. citizens maintained a strong interest in Polish culture and the homeland. They established innumerable social and cultural organizations, including the Polish National alliance, the Polish Roman Catholic union and the Polish-American congress—all with headquarters in Chicago. By 1950 there were about 800 Roman Catholic Polish parishes. The number of Polish-language schools and publications, although tending to decline, remained large, in 1950 there were 600 primary schools, with 300,000 pupils, and 20 higher schools. Out of a total of 96 Polish periodicals appearing in the United States there were 9 daily newspapers.

The largest group of emigrants in Europe went to France, setting for the most part in the northern mining areas. After the onset of the economic depression they declined from 800,000 to about 600,000 in 1939. In 1950 they probably numbered fewer than 500,000. In the Ruhr, the "Westphalian" Poles formed another considerable group but, like their compatriots in France and Belgium, were somewhat reduced in numbers by World War II and by postwar repatriation, numbering fewer than 100,000 in 1950.

Many thousands of Polish refugees were driven abroad by World War II, and smaller numbers continued to escape across the Polish frontiers, defying the general ban on emigration. Many of these refugees went to those countries where large colonies existed already, particularly the United States and France, Canada and Australia (where there were 2,000 Poles before the war). The greatest change brought about by the war was the establishment of a Polish colony in Great Britain, where the Polish government had its seat. The majority of the Poles in Great Britain was constituted by the 100,000 ex-servicemen and their families who were assisted by the Polish Resettlement corps in finding civilian employment. Most of the political émigrés settled in London.

After the derecognition of the Polish government in London a shadow organization continued with president, government and national council. Most of the larger political parties in exile—the

Socialist, the National and the Freedom and Independence, with a peasant group—organized the Polish Political Council, with its headquarters in London. A third political grouping, the Polish National Democratic committee, mainly Peasant party was established in Washington, D.C. These various groups maintained contacts with the European movement, the International Confederation of Free Trade Unions, the Peasant International, the National Committee for Free Europe in the United States, etc. A special British-Polish committee under the ministry of education supervised the Polish schools in Great Britain. A Polish university college in London, a Polish research centre, the Sikorski Historical Institute and many cultural, social, professional and trade organizations were established. There were numerous Polish publications in Great Britain at mid-20th century, including an independent daily paper, the *Dziennik Polski*.

The United States made special provision in excess of the usual quota to enable Polish ex-servicemen and displaced persons to enter the country. Various funds were established to assist the general relief work. The Paderewski foundation of New York did much to help the Poles, particularly in cultural matters, in which it supplemented the work of the Kosciuszko foundation (established 1925).

GOVERNMENT, DEFENSE AND EDUCATION

Constitution.—The constitution of 1921 was based on the best democratic traditions of Poland and of the western nations. It was superseded by the constitution of 1935, which, reflecting the internal political disputes and the mood of the prevailing international situation, showed what the major political parties described as quasi-authoritarian tendencies. After the dismemberment of Poland in 1939 and the subsequent regrouping of military and political personalities, the exiled leaders signed the Paris agreement of 1939, by which the powers of the president under the constitution of 1935 were modified. To speak generally, the standpoints of the three major émigré groups were determined in relation to these constitutional changes, the Polish National Democratic committee supporting the constitution of 1921, the Polish Political Council standing by the Paris agreement and the government in exile clinging strictly to "legal continuity" and the constitution of 1935 until such time as it could be constitutionally modified in the homeland.

The Communist party, which was illegal before 1939, introduced a barely disguised single-party system when it got control. The stages in this development were (1) the formation in the U.S.S.R. of the Polish National Committee of Liberation, representing the Communist-controlled groups which later formed the nucleus of the postwar government, (2) the elections of Jan 19, 1947, to a single-chamber *sejm*, the elections being weighted entirely in favour of the Communist-controlled bloc of parties, (3) the Constitutional act of Feb. 19, 1947, which quoted freely from the constitution of 1921, passed immediately by the new *sejm* and known as the "small constitution." This *sejm* was to have a life of five years and was charged with the task of passing a permanent form of constitution.

Several subsequent constitutional amendments further confirmed the government in its power to rule by decree and reduced the *sejm* to a body merely registering approval. The Polish United Workers' (Communist) party exerted control over all governmental and administrative bodies, both national and local, by direct membership and by duplicate party organizations. The highest officials, the president and leading ministers such as those controlling defense, security, economics and justice became members of the Politburo.

According to the "small constitution" in force from 1947 to 1952, the supreme organs of government were (1) the president of the republic, elected for seven years; (2) the *sejm*, elected for five years, (3) the state council with the president as chairman, other members being the speaker and deputy speakers of the

sejm, the commander in chief of the armed forces in time of war and up to three other members appointed by the *sejm* and unanimously approved by the state council, (4) the council of ministers under the chairmanship of the prime minister, the cabinet council consisting of the council of ministers under the chairmanship of the president of the republic, (5) the supreme chamber of control under a president elected by the *sejm*, functioning as a supreme auditing and control authority; (6) the courts of justice, theoretically independent but gradually remodelled into an instrument of the Communist party.

Defense.—Between the armed forces of pre-World War II Poland and those established after 1945 there was no continuity, personnel, organization, training and equipment were completely changed. The Polish army suffered catastrophically from the German and Soviet invasions, although certain naval, army and air force units escaped abroad and made an uninterrupted and important contribution to the Allied war effort from the Polish headquarters in Britain. The fate of the Polish units in the east, their imprisonment, release and recruitment into the Polish army under Gen. Władysław Anders, their exodus from the U.S.S.R. through the middle east and their subsequent battle engagements in the battle of Britain (during which the Polish airmen shot down 14% of the enemy aircraft destroyed), at Narvik in Norway, at Tobruk in Cyrenaica, at Monte Cassino in Italy and at Falaise in France provided one of the great epics of World War II. Out of 215,000 Poles fighting with the Allies in the west, 150,000 chose to remain in exile, and those who returned were not allowed to form any part in the new defense organizations.

A Communist-dominated Polish army was organized in the Soviet Union in 1943 and 1944, eventually numbering ten infantry divisions, an armoured corps and an air force.

Between 1944 and 1947 the Communists were occupied with the liquidation of the Polish home army, the main fighting organization of the underground government, which was supported by the mass of the people and directed by the Polish government in London until its derecognition in 1945. By 1947, aided by the presence in strength of the Soviet army and by the Communist militia, a new "people's army" had been established around the nucleus formed in Russia. On Nov. 7, 1949, Marshal Konstantin Rokossovsky (thenceforward Konstanty Rokossowski) was transferred from his command of the Soviet army troops stationed permanently in the Polish recovered territories at Legnica (Liegnitz) to become Polish minister of defense and commander in chief; on May 8, 1950, he also joined the Politburo of the Communist party. Many other Soviet officers acquired key positions in the Polish forces, which were modelled on the Soviet prototypes.

Including the forces of the interior (frontier guards, security troops), the Polish armed forces were thought to have reached a total of more than 500,000 by 1950. There were then four military areas (Warsaw, Bydgoszcz, Wrocław and Cracow) comprising 16 divisions. By 1952 it was believed that four more divisions had been formed. In addition, Soviet army and air force units were maintained in the recovered territories and naval units at Swinoujście and the former Polish naval base at Oksywie; the extraction of uranium ore in the neighbourhood of Jelenia Góra (Hirschberg) in the Sudeten mountains was a strict Soviet monopoly. The Polish navy in 1950 consisted of 1 destroyer, 3 submarines, 2 motor-torpedo boats, 13 minesweepers and 12 submarine chasers.

Military service was made universal and compulsory between the ages 20 and 50. In 1950 active service was two years in the army, three years in the air force and the navy, two years in the anti-aircraft units and 27 months in the forces of the interior. Women were called up for six months' active service. Preliminary training was afforded by the youth clubs and the Service for Poland brigades.

Education.—Before 1939 the educational system was based on the principle of free and compulsory elementary education for all between the ages of 8 and 15 years, with nursery schools serving younger children from the age of 3. Secondary education, which was selective, was provided in two stages, the grammar schools for those aged 12-16 years and the lycea for those aged 16-18, the

latter being maintained by the state, the municipalities and private organizations. In addition, there was a great variety of trade and professional schools which afforded theoretical and practical professional training as well as general education. The universities, of which several were ancient foundations, preserved the independent traditions of the finest schools of Europe. The educational authorities had been faced with the great task of unifying the former German, Russian and Austrian components of the new republic, in the last two of which illiteracy was widespread. In the great release of Polish intellectual life which began in 1918, the needs of the various national minorities were not forgotten.

The Germans in World War II attempted to destroy the educational and cultural system which had been steadily fostered by the Polish republic. In the incorporated areas no Polish schools were permitted, the Polish tongue was forbidden and the University of Poznan was entrusted with the special mission of propagating German culture. In the area of the so-called *General Government*, a restricted number of elementary and technical schools was permitted, while the teaching of all subjects dealing with Polish affairs was strictly excluded. The losses in personnel and property were enormous, the damage to buildings and the destruction of libraries, collections, museums, archives and records almost incalculable. More than 1,500,000 orphans were left to be cared for. Only the strength and deep-rooted nature of Polish culture, instructed by its historic experiences and aided by the great progress achieved up to 1939, enabled it to survive the onslaught of the invaders.

The policy of the post-1945 Polish government was the gradual replacement of the old system by a Stalinist-Marxist one at every level. The state control and censorship of all organs of information rendered this policy more effective. The influence of the state and, therefore, of the Communist party became absolute, private and independent institutions (such as those organized by the Roman Catholic Church, the Lutheran Church, the religious orders and the scientific and historical societies) had by 1952 been closed down or subjected to governmental interference. The enormous task of postwar rehabilitation called for state support and opened the door to party control. The development of the new educational system proceeded most easily in the regained territories, where a clear field was presented to the Communist organization, the Society of the Friends of Children, to plan schooling and the training of teachers on lines excluding those aspects of the former system to which the party objected. Besides the steady imposition of Marxist uniformity, the government was confronted with the need to supply trained citizens to man the ambitious program of industrial expansion, maintain and if possible improve technical standards and fill the ever-increasing state services, civil, security and military, and the public utilities. At mid-20th century there was free, compulsory and universal education for the nursery, primary and intermediate stages, which covered the years from 4 to 6, from 7 to 15 and from 15 to 18 or 19. No member of the community, except those too young for the factory crèches or nursery schools or too infirm to attend one of the numerous adult classes (which included even elementary tuition), was far removed from one course or another. Political instruction permeated every other form of education, from highest to lowest, and all organized cultural and recreational activities as well, the classroom, lecture hall, factory workshop, tractor station, barracks room, sports club, press, radio, motion picture and theatre were all subject to it.

The work of education was therefore shared by the governmental organs and the party officials. In 1952 the ministry of education controlled the lower schools, nursery, primary and intermediate, both general and vocational, the technical and special schools and supplementary courses on the appropriate level, and the central office of vocational training. The ministry of higher schools and learning controlled the universities, colleges of engineering and the increasing number of institutions affording specialist training at the highest level. The Supreme Technical organization, embodying all the technical associations of Poland, also came under the ministry of higher schools. The organization of the medical, pharmaceutical, dental and nursing professions

was the concern of the ministry of health. The medical faculties were detached from the universities, and 11 medical academies had been established by 1952.

The senior learned societies of pre-1939 Poland were the Polish Academy of Learning in Cracow, founded in 1872, which maintained stations in Paris and Rome, and the Warsaw Scientific society, reopened as a continuation of the erstwhile Royal Society of the Friends of Science, dating from the 18th century. Both were seriously affected by the depredations of war and postwar political conditions. At the first congress of Polish science, held in Warsaw in July 1951, a new Soviet-type Polish Academy of Sciences was initiated, this body, in collaboration with the various government departments and party committees, was created to ensure the conformity of all higher learning and research with Stalinist-Marxist dogma. Chairs of dialectical and historical materialism and Michurin genetics had already been established at the Polish universities.

Schooling was assisted at every level by free tuition, and the granting of scholarships for those attending higher schools was theoretically automatic. Qualifying certificates had to be supplemented by approval from the Union of Polish Youth, which could prevent a student's passing from one stage to the next by describing him as unsuitable. Class origin was another important qualification, it being an advantage to emanate from a proletarian or peasant background. Finally, students were closely influenced in their permitted specializations by state requirements and in their subsequent employment by the general direction of labour.

In the year 1949-50 Poland had 5,860 kindergarten schools, with 343,000 pupils, and 22,417 primary, with 3,242,000. Secondary schools (1948-49) comprised 325 grammar schools, with 197,110 pupils, 486 lycees, with 140,893, and 1,131 vocational, with 183,440. Teachers' colleges numbered 149, with 32,570 students, in 1950-51.

Higher academic institutions had 96,762 students in Dec 1949, distributed as follows: in Warsaw, 9,793 at the university, 5,733 at the College of Engineering, 2,113 at the College of Agriculture, 2,129 at the Academy of Planning and Statistics, 314 at the Gen. K. Swierczewski Academy of Physical Culture, 2,866 at the Academy of Political Science and 324 at the Academy of Fine Arts, in Torun, 3,139 at the Copernicus university; in Poznan, 8,809 at the university and 3,124 at the Academy of Commerce, in Lodz, 8,658 at the university, 2,065 at the College of Engineering and 745 at the Academy of Planning and Statistics; in Lublin, 3,327 at the Marie Curie-Skłodowska university and 2,030 at the Catholic university, in Gdansk (Danzig), 3,017 at the College of Engineering and 1,805 at the Medical academy, in Szczecin, 309 at the Gen. K. Swierczewski Medical academy and 2,060 at a branch of the Poznan Academy of Commerce, in Wrocław, 8,385 at the university and 2,322 at the College of Engineering; in Bytom, 625 at the L. Warynski Medical academy; in Gliwice, 3,051 at the College of Engineering, and in Cracow, 11,301 at the Jagiellonian university, 4,758 at the Mining and Metallurgical academy and 404 at the Academy of Fine Arts.

The loss of the eastern territories deprived Poland of two of the oldest universities, the Stephen Bathory at Wilno (founded in 1578) and the John Casimir at Lwow (1668), although a part of the latter was transferred to the new university at Wrocław. Three other universities were founded after 1945, viz., those at Torun and at Lodz and the Marie Curie-Skłodowska university at Lublin. The greatest development in higher schools was in the vocational sphere. By 1950, there were 39 institutions in this category, with 18,816 students. They were distributed in Warsaw (engineering, psychology, law, pedagogy, plastic arts, drama, music), in Poznan (engineering, music, plastic arts, operations), in Lodz (agriculture, pedagogy, music, plastic arts, films, drama), in Gdansk (Danzig) (engineering, pedagogy), in Sopot (naval commerce, fine arts, music), in Szczecin (engineering), in Wrocław (commerce, pedagogy, music, plastic arts), in Cieszyn (Teschen) (agriculture), in Czestochowa (engineering, commercial administration), in Katowice (economic administration, pedagogy, music, plastic arts) and in Cracow (social sciences, pedagogy, music, plastic arts, drama). The larger of these schools were the techni-

cal schools in 'Warsaw (the former Wawelberg and Rotwand), Poznan and Szczecin, with 1,183, 1,526 and 1,519 students, respectively, the Gdansk evening college of the supreme technical organization, with 886, the Sopot Higher College of Overseas Trade, with 777, the Wrocław Academy of Commerce, with 2,376, and the state higher colleges, of economic administration in Katowice, with 1,947, and of social sciences at Cracow, with 1,061

ECONOMIC CONDITIONS

There was a certain similarity between the problems facing the Polish government in 1918 and those in 1945. After World War I losses of national wealth had to be made good and the differing systems of the Austrian, Prussian and Russian zones unified into one viable whole. World War II, it was estimated, destroyed 38% of the total national wealth, more than three times as much as World War I. In addition, Poland had acquired important new territories and lost 45% of its former area. Apart from the work of reconstruction, however, the new state embarked upon an ambitious program of industrial development and was forced to set about transforming the old economy into one based on Stalinist-Marxist theories. The period 1945-51 was essentially a transitional one, the organization of industry, trade, finance, labour, trade unions, co-operatives and social welfare having been fundamentally changed from that of the prewar days. By 1952 the adoption of Soviet forms was practically complete.

The breach with prewar days was made more complete by World War II, for the German control of key industries paved the way for the transfer to state ownership, just as the tremendous scale of destruction called for state planning and reconstruction. The acquisition of the German part of the Silesian industrial complex and of additional Baltic ports further emphasized the changed conditions. Direct comparisons between the two Polands should be made only in the light of these changes. Comparisons are rendered difficult because Polish statistics after World War II were published in incomplete form or withheld altogether.

In conformity with all the other undertakings of the new state, the financial system of Poland after World War II was changed in accordance with Stalinist-Marxist theories. The most fundamental of these changes were as follows:

1. The power of the private individual was restricted by a variety of methods, such as the confiscation of property under the Land Reform and Nationalization of Industry acts, the licensing and tapering off of the private sector of industry, the liquidation of the independent functioning of banks, co-operatives, insurance companies, the retail, wholesale and distributive trades, the trades unions and the professions; revaluation and reform of the currency, enforced "social saving"; the manipulation of income tax and land tax to the disadvantage of the "class enemies"; the regulation of the rationing system and the price-wage relation to the same end and to increase the dependence of labour upon the state, the operation of the arbitrary, punitive powers of the Special Commission for the Investigation of Economic and Social Abuses, the head of which was a member of the Politburo of the United Workers' (Communist) party.

2. The liquidation of foreign (i.e., excluding Soviet) ownership was achieved under the terms of the Nationalization of Industry act. Foreign investments before 1939 had been considerable and were officially estimated in 1947 to have been 52% of the total in mining, 87% in the petroleum industry, 66% in electro-technical production, 60% in the chemical industry, 80% in power stations and 59% in insurance.

3. The state monopolized investment, banks, credit institutions, insurance, etc.

4. Poland was reduced to dependence on the U.S.S.R., under the general terms of the treaty of friendship and mutual assistance signed on April 21, 1945, and under the provisions of the subsequent trade and economic agreements, as well as by membership of the Moscow Council for Mutual Economic Aid.

Budgets for the years 1947-52 are shown in Table IV.

Planning and Administration.—The basis of the reorganization of industry was the Nationalization of Key Industries act of Jan. 1946, which expropriated without compensation all form-

erly German-owned property. All key industries and other enterprises with more than 50 workers per shift were nationalized, Polish nationals and non-German foreign owners being able to bring claims for compensation before the appropriate commission.

TABLE IV.—Budgets, 1947-52
(in million zlotys)

Item	1947	1948	1949	1950	1951*	1952*
Revenue	228,400	325,444	619,038	1,265,800	55,072	61,787
Expenditure	207,700	325,740	612,038	1,265,800	51,801	62,876

*In new zlotys. On Oct. 28, 1950, the zloty was revalued and brought at par with the Soviet rouble. The new exchange rates were (old in parentheses): 21 = 12 20 (280 00) zlotys, 1 = 4 20 (100 00) zlotys.

Compensation of foreign claimants was usually finally agreed upon with countries in great need of coal, Poland's most valuable asset.

Ministries of reconstruction and of recovered territories were formed temporarily to tide over the first period of rehabilitation. The first co-ordinated plan of development was embodied in the three-year plan of 1947-49, during which period productivity was to be restored and the level of 1939 regained. The six-year plan to be restored and the level of 1939 regained. The six-year plan covering the period 1950-55 aimed at big increases over the level of 1949, with emphasis upon the production of capital goods and heavy industry, Poland in fact was being transformed from a predominantly agricultural to a mainly industrial country. The private sector of trade and industry, still important up to 1949, dwindled rapidly after 1950 under the influence of the government's licensing and fiscal regulations and political doctrines.

The economic administrative system was reorganized during 1950 to conform with that existing elsewhere in eastern Europe. The ministry of industry and commerce was subdivided, and eventually separate ministries were established for mining, heavy industry and power, light industry, chemical industry, agricultural and food industry, internal trade and foreign trade. Co-ordinating the work of these ministries was the chairman both of the economic committee of the council of ministers and the state planning commission who was, moreover, a member of the Politburo of the Communist party.

Industry.—The progress of industrialization can be seen in the proportion of persons engaged in nonagricultural occupations, it was 38.6% of the total in 1931 and 54.25% in 1951. The change was not brought about solely by postwar planning. The trend was already apparent before 1939, as the republic overcame the stagnation of earlier days and set about such projects as the building of the port of Gdynia and the development of the central industrial region in a wide area centring on Sandomierz. The German war machine also stimulated certain industries. Most of all, however, the change was brought about by the acquisition of the former industrial centres of German Silesia. The plebiscite of 1921 had left Beuthen (Bytom), Hindenburg (Zabrze) and Gleiwitz (Gliwice) on the German side of the frontier and Chorzow-Krowiecka Huta and Katowice on the Polish side. Poland, which had had insufficient coal before 1921, then received a useful surplus, after 1945 the country had a superabundance.

One of the most serious problems before the Polish planners was the transfer of the German population to the new territories.

As in other countries, the new territories were developed by the "Stakhanovite" methods and labour competitions were applied according to Communist practices, in 1948 a compulsory labour service (Service for Poland) was introduced, by which young persons between 16 and 21 were employed on all manner of projects; in 1951 a decree raising the minimum age of employment from 15 to 16 also made it possible for industry to engage juveniles in training for work from 14 years of age, for not more than 6 hours daily

or 36 hours per week. Lastly, as in the other countries of the Soviet bloc, forced labour camps supplied prisoners, especially for work in the mines.

The relative importance of the various industries is illustrated in Table V. The great preponderance of coal, with iron and steel works and textile mills in the second place, is clearly seen. The largest single industries, each employing more than 30,000 workers, are the coal mines, cotton mills, ironworks and woollen mills of the larger towns, and the sawmills and sugar refineries of the forests and farmlands of the rural areas, these provide the characteristic industrial landscape of Poland. Most of the leading industries showed a considerable increase above the prewar level, but the timber, petroleum and natural gas industries lost many establishments in the sub-Carpathian areas incorporated into the USSR. Figures for 1950, though details were not published, show the general increase above the level of 1946 as given in Table V, out of a total of 1,763,000 wage earners in industry, 886,000 were employed in heavy industries and mining, 732,000 in light industries and 145,000 in foodstuffs and kindred industries.

TABLE V—Wage Earners in Industry
(Annual averages, in thousands)

Industry	1937	1946	Industry	1937	1946
Mining	88	202	Agricultural machinery, etc.		9
Coal	88	202	Machinery and tools		9
Iron ore	5	165	Foodstuffs, etc.	86	117
Textiles	74	181	Sugar	48	86
Cotton	74	181	Building	81	81
Woollen	36	138	Stone, glass, cement, etc.	43	66
Bast fibre	15	15	Chemicals	68	62
Knitted	16	16	Wood and timber	15	44
Synthetic fibre	61	70	Clothing	19	20
Metallurgy	37	137	Paper	10	20
Ironworks	37	137	Electrotechnical	13	15
Metal	104	130	Printing	14	15
Rolling stock	10	10	Petroleum, etc.	14	15
Cast iron and steel	20	20	Total number of industrial workers	825	1,126
Wire, nails, etc.	11	11			

Heavy Industry—Heavy industry was given first place in the post-World War II economic plans. It was based on possession of the Silesian coal fields and the iron ores, zinc and lead of Silesia and central Poland.

The main field is formed by the coal measures underlying Upper Silesia and reaching the surface near the pre-1939 German-Polish border. It is comparatively little faulted and is composed of thick seams which facilitate the use of mechanical methods of extraction. It is divided into the Silesian basin (cut by the pre-1939 German border), the Dabrowa basin and the Cracow basin, of which the first was by far the most important one developed at mid-century. The coal is of good general-purpose type. The second coal field, another valuable acquisition from Germany, is the smaller one of Walbrzych (Waldenburg), noted for fine metallurgical coking coal.

Coal is the greatest single Polish national asset, the basis of heavy industry and the most valuable export, enabling Poland to import the necessary supplementary raw materials and capital goods for industrial development. In 1938 output was 38,100,000 metric tons (excluding 26,000,000 in the German part of Upper Silesia), exports about 10,000,000. In 1948 output was 70,260,000 tons, exports 24,000,000, the biggest consumers being Sweden and the Soviet Union; in the same year the output of lignite was 5,000,000 tons and coke 3,000,000 tons. The output of coal had risen to 78,000,000 tons by 1950.

Iron ores are mined in the Jurassic limestones near Radom, other ores are found near Cracow and in Upper Silesia. The metal industry imports large quantities of ore from Sweden and some from the Soviet Union. The foundries, iron and steel plants and metallurgical industry generally are concentrated mainly in Upper Silesia. An entirely new iron and steel centre was under construction in the early 1950s at Nowa Huta near Cracow, with the Soviet assistance promised, this was expected to become one of the most important steel towns in central Europe. The six-year plan also provided for the extension of the existing works at Czestochowa. In 1947 the output of crude iron ores (mainly lumpy and brown ores, 32%–34% metal content) was 544,000 tons, of zinc metal 75,000 tons, of lead 13,000 tons, of pig iron

867,000 tons and of raw steel 1,580,000 tons. The output planned for 1955 was fixed at 3,000,000 tons of iron ore, 198,000 tons of zinc metal, 3,500,000 tons of pig iron and 4,600,000 tons of raw steel.

Textiles—In the days of the Congress kingdom a textile industry sprang into being, developing subsequently under the imperial Russian regime in the latter half of the 19th century into the great supplier of Russian and eastern markets. Partly destroyed in World War I, the industry was reconstructed in 1919. Lodz became the main centre, with cotton goods, woollen goods, hosiery, etc. Bialystok was noted for woollen rugs, haberdashery and garments, Bielsko for high-quality combed-wool fabrics, Warsaw for linens, knitted goods and hosiery, Zyrardow, Czestochowa and Cracow for linens. After 1945 war damage once more had to be made good and steady supplies of raw materials provided. New machinery and equipment were obtained from the Soviet Union, now in much the same relation as the Russian empire had been formerly, and from Great Britain. The output of yarn in 1947 (in metric tons) was cotton 59,000 (compared with 78,000 in 1937), woollen 24,000, linen 11,000, jute 9,000 and rayon 6,000. The output of fabric was cotton 47,000 (compared with 52,000 in 1937), woollen 17,000, linen 8,000, jute 8,000, rayon 3,000 and knitwear 5,000.

Electric Power—An integral part of the three-year and six-year plans was the reconstruction, integration and expansion of the network of high-tension lines. The networks existing in 1945 were in well-defined regions, drawing their supplies mainly from thermoelectric power stations. (1) Silesia, primarily the Katowice area, which, however, linked up with Cracow to the east, and the former German concentrations in Wroclaw and Walbrzych—a region supplemented by hydroelectric stations in the Sudeten valleys and the uplands bounding Silesia to the north, (2) the central industrial region, with stations at Lublin, Radom, Stalowa Wola, Kielce and Rzeszow and a dam on the river Dunajec to the south, (3) the Warsaw, Lodz and Poznan systems, (4) the Piotrkow-Czestochowa system, (5) the lower Vistula and Gdansk, with both thermoelectric and hydroelectric sources; (6) the former German systems of Szczecin and Olsztyn. An important step was the linking of the Silesian grid with Lodz in 1947, the first stage in bringing the great resources of Silesia to the coast at Gdansk (Danzig). Dams being built on the upper Vistula not only would help to control the seasonal floods which follow the spring thaw but also would swell the electricity supplies.

Electric power production in 1938 was 3,900,000,000 kw hr, within the post-1945 boundaries, production would have been 7,000,000,000 kw hr. In 1947 actual production reached 6,600,000,000 kw hr and the 1955 planned production was fixed at 19,300,000,000 kw hr.

A necessary adjunct to electric power production was the electrochemical industry, centred mainly in Warsaw, Wroclaw and other Silesian centres.

Oil—Before 1939 Poland was one of the three major producers of petroleum in Europe. The fields, which were also associated with natural gas, were situated along the sub-Carpathian foothills. The wells centred mostly around Boryslaw and the refineries around Drohobycz. Most of these resources were acquired by the Soviet Union, although some oil was still produced and natural gas piped to the larger towns. Average yearly output of crude oil in 1936–38 was 598,300 metric tons, 40% of the refined products were exported, central Europe being the natural market. The home production was to be raised to 394,000 tons by 1955. Poland imported oil at mid-20th century.

Chemicals and Fertilisers—A wide variety of chemicals is produced. The prewar fertilizer industry was centred in two state-owned factories, at Mosice near Tarnow and at Chorzow. Poland before 1939 was third in the European production of potassium salts, coming after Germany and France; the deposits were in the southeastern area at Kalusz, Holyn and Stebnik, but, as this region was incorporated into the U.S.S.R., Poland became an importer from eastern Germany. Salt is obtained in Poznan, Silesia, the Cracow basin and Warsaw province, mostly in the form of rock salt from the mines at Wapno, Wieliczka (worked since 1040) and

Bochnia Production amounted to 643,000 tons in 1938 and 619,000 in 1947

Industrial chemicals are produced in conjunction with the other main industries, coal, metallurgical and textile, and production and demand were stimulated by the acquisition of the new territories and the expansion of heavy industry. Large increases were planned during the period 1950-51, especially in the basic chemical, sulphuric acid (see Table VI).

TABLE VI—Production of Chemicals
(In thousands of tons)

Chemical	1937	1947	1950*
Superphosphates	164	184	260
Cyanamide of lime	68	121	7
Nitrates	10	70	231
Burnt soda	9	12	280
Caustic soda	22	31	163
Dyes	2	4	5
Sulphuric acid, 100%	74	48	590
Rubber latex and tubes	7	4	7

*Finished

Two new chemical factories were built, one at Dwory near Oswiecim and the other at Brzeg (Brieg) in Lower Silesia, the former for synthetic oil, the latter for synthetic dyes.

Building Industry—The building trade in Poland was pressed to the utmost to provide the wherewithal for the restoration and reconstruction of property damaged during World War II in every sector of the national life. Salvaged materials, volunteer labour and youth brigades were employed on a large scale. To cope with this and with the new work of construction under the six-year plan, the production of lime and cement, bricks and building stones, and timber received special consideration. Cement production, one of the more important industries, is associated with the calcareous rocks of central Poland. Production of cement amounted to 1,719,000 tons in 1938 and to 1,512,000 tons in 1947; the aim for production in 1955 was fixed at 5,000,000 tons. To the previous supplies, those of the Opole (Oppeln) area were added, a new plant, the "Odra" at Opole, completed in 1951, was reputedly the largest in Poland (followed in size by the plant at Wierzbica, near Radom, and next by that built in 1951 at Rejowiec, near Lublin).

Miscellaneous—Other industries are glass, ceramics and pottery, based on the sands, clays and kaolin deposits of central and southern Poland and widely exported, leather and footwear, and paper.

Rural Economy—Farming and forestry (for the latter see *Physical Geography*, above) and the related foodstuffs and timber industries remained among the more important pursuits at mid-century. The farming population had, however, declined to a secondary position from 70% of the total in 1918 and 65% in 1938 to 45% in 1950. The people in rural areas, as in all other sectors, suffered heavily from the effects of both World Wars I and II. The restocking of farms was not complete until about 1927, the war with the Soviet Union not ending until 1921, six years after 1945 the position was still far from being restored, a vital factor when it is considered that horses were still the main draught power in Poland. Figures for livestock are given in Table VII.

TABLE VII—Livestock
(In thousands of head)

Livestock	1938*	1947	1946	1950
Horses	3,016	3,100	1,730	2,797
Cattle	10,554	9,090	3,010	7,184
Pigs	7,535	9,100	2,074	9,028
Sheep	3,411	1,000	277	1,104

*Within pre-1938 boundaries
†Within post-1945 boundaries

Climate and soils combine to give Poland a mixed type of farming and a relatively high proportion of cultivable land. At mid-century the percentages of the total surface under cultivation, forest and lying waste (including fallows and water surfaces) were, respectively, 68, 22 and 10—roughly similar to those in 1939, except that the forest area was smaller by 2%. The main crops were grains (rye, oats, wheat and barley), potatoes, sugar beets

and fodder crops (see Table VIII). Rye and potatoes are more characteristic of the poorer sandy soils (the podzols) of the glaciated regions, wheat and sugar beets of the more fertile brown and chocolate-brown soils (the *radzimes*) of southern Poland. Vineyards were found only in favourable situations around Wrocław, since the former area of warm fruits in the extreme southeast was incorporated within the Soviet Union. Hops and tobacco are located on favourable soils in the centre and south. Temperate fruits, dairy, poultry and pig products are part of the general farming in most districts of the country. Sugar production surpassed the prewar level of 506,000 tons and in 1950 was estimated at 955,000 tons.

TABLE VIII—Agricultural Production
(In thousands of metric tons)

Product	1938-38*	1934-35†	1948	1949	1950
Wheat	2,054	2,210	1,630	1,758	1,844
Barley	1,417	1,600	1,010	1,038	1,077
Rye	4,457	7,070	6,304	6,750	6,503
Oats	2,558	3,450	2,409	2,333	2,140
Potatoes	35,066	31,710	20,756	20,000	30,845
Sugar beets	2,805	4,750	4,120	5,085	6,377

*Yearly average within pre-1938 boundaries

†Yearly average estimated for post-1945 boundaries.

The tendency at mid-20th century was to concentrate upon crops of value to the export market, such as sugar, poultry products, bacon and hams, the Soviet Union and United Kingdom being chief customers. Although Poland's export of sugar was in 1947 double what it had been in 1937, other formerly noted exports were considerably down, for example, the export of eggs was only one-twelfth the prewar quantity. The demands of the export drive and the virtualising of the steadily increasing military forces, coupled with the direction of labour into heavy industry, imposed heavy burdens upon the ordinary civilian consumer. Changes in the agrarian system also contributed to the difficulty of adequately feeding the Polish population. As a result, internal food shortages became once more apparent in 1948, grew worse in 1950 and 1951 and led to the re-introduction of food rationing at the beginning of 1952. In 1947 grains and flour were imported from the Soviet Union (310,000 tons), from the United States (139,000 tons) and from Hungary and Denmark.

Agrarian Reform—As in industry, Stalinist-Marxist dogma was applied to the ownership of land and the system of production, although the change was less sudden because of the greater difficulties involved. The ultimate objective was the complete socialization of agriculture on the pattern of the Soviet Union. These aims had been realized only partly by 1952.

Agrarian reform had been in progress in Poland since the Agrarian act of 1920 and its modification in 1925, which set aside for parcelation among the peasants the vast state domains of the Russian, Prussian and Austrian governments, certain ecclesiastical and public property, as well as the largest of the privately owned estates. More than 8,000,000 ac were reallocated in the period 1920-38, the former owners receiving compensation, the total number of people who received land through parcelation was 734,100. Small peasant farmers occupied more than half of Poland, especially in the then central and southern areas, while the large estates were mostly in the eastern and western borderlands.

The first step in the Communist plan for agriculture was taken in July 1944, when the Polish National Committee of Liberation (the Lublin committee which later formed the real nucleus of the postwar government) passed a decree on agrarian reform. A land fund was set up to receive the land taken over from the former republic of Poland or confiscated from German owners and from persons who had collaborated with them and also from all owners of estates with more than 125 ac of cultivable land. Church estates in excess of those needed to support the parish priests were decreed by a decree issued in 1950. The main purpose of the decrees was not so much the satisfaction of peasant claims to ownership, which was in effect only nominal, as the creation of state farms (the Soviet *sovkhozy*) and production co-operatives (the Soviet *kolkhozy*), in short, a Stalinist-Marxist type of rural economy. Hand in hand with the gradual development of

collective farming went the development of the state-owned machine tractor stations or MTS (virtually holding the monopoly of mechanical farming) and the replacement of the former international renowned co-operative system, as applied to wholesale, retail and distributive trades and the provision of credit, by one under state control. The rate of development of collective farming is illustrated by the following figures: in 1946 there were 9,500 tractors in the whole of Poland and no collective farms, in 1947, 13,050 tractors in 30 MTS supplying 243 collective farms, by 1950, 18,000 tractors, 156 MTS and 2,200 collective farms.

In connection with the planning of agriculture under the six-year plan, the Polish government in the autumn of 1949 carried out a survey of rural areas, termed a "social classification of the land." In Dec. 1949 there were said to be in Poland 1,252,000 farms of 5-7.5 ac., 650,000 of 7.5-12.4 ac. and 200,000 of "medium size" (presumably 12.4-123.5 ac.).

Commerce.—The transition from a mixed to a Communist economy was paralleled by important changes in the economic relations of Poland. The six-year plan was largely dependent upon a vast program of capital investment and the production of capital goods, requiring loans and equipment from abroad as well as an unprecedented internal effort. That Soviet influence was paramount was demonstrated by the conclusion of a five-year trade and economic agreement on Jan. 26, 1948; Poland was to pay principally with coal and goods to be manufactured by the industries developed, particularly iron and steel, shipbuilding and textiles. Poland was forced to reject co-operation with the European Recovery program and became instead a member of the Council for Mutual Economic Aid in Moscow. Trade with Yugoslavia was stopped at the bidding of the Cominform. Relations continued to develop with other states of the Soviet bloc, particularly with Czechoslovakia, whose exports went down the Oder to the Polish ports and shipping lines rather than down the Elbe to Hamburg as formerly. Financial integration with the eastern European system was completed on Oct. 28, 1950, when the Polish currency was reformed and the zloty equated with the rouble.

The Soviet Union was not the only source of assistance in the three-year and six-year plans. On Jan. 14, 1949, the United Kingdom signed a five-year agreement by which Poland was to receive a variety of goods, including machinery, machine tools, ships, etc., in return for food and other products. The Scandinavian countries—Switzerland, Austria, the Netherlands, Belgium, France and Italy, anxious to obtain Polish coal (which had little to fear from the competition of the pre-war British and German exporters), all made important contributions to Poland's planning. By 1951, however, increasing political differences induced the countries of the North Atlantic Treaty organization to curtail the export to Poland of goods classified as strategic.

TABLE IX.—Volume of Foreign Trade
(In thousands of metric tons)

Volume of export trade			Volume of import trade		
Leading exports	1937	1950	Leading imports	1937	1950
Minerals	11,251	33,281	Minerals, mainly iron ore	2,050	3,146
of which coal	11,000	32,214	Chemicals, etc.	256	1,072
Timber	1,696	748	Grains, plant products, etc.	209	425
Base metals, etc.	303	336	Base metals, etc.	730	317
Foodstuffs, etc.	138	277	Timber, etc.	19	395
of which sugar	52	237	Textile raw materials	146	152
Products of plant origin	611	261	Machinery, etc.	21	35
Chemicals, etc.	230	118	Paper, etc.	56	75
Animal products, etc.	89	104	Transport facilities	10	71
Transport facilities	0.7	112	Rubber, natural and synthetic	8	20
Glass, ceramics, etc.	20	42	Total volume of imports	3,685	5,827
Textiles	45	21			
Paper, etc.	14	20			
Machinery, etc.	4	15			
Total volume of exports	14,097	34,870			

TABLE X.—Direction of Trade
(Value in percentage of total)

Country	Average, 1937-38	1947
Soviet Union	11.1	25.1
Germany	17.6	2.1
United Kingdom	17.3	0.6
Sweden	1.1	0.0
United States	12.0	16.0
France	2.7	4.8
Brazil	1.4	4.8

For the volume of imports and exports see Table XX, for the direction of trade, see Table X.

After 1945 and more especially during the period of the six-year plan, while relations reached a very low ebb with the United States and became strained with the other western powers, Poland developed trade contacts with the middle east, with Indonesia and with Communist China. With the establishment of new shipping lines, Polish ships became an important factor in the carrying trade of the orient. The two great Polish port authorities, Gdynia-Gdansk (Danzig) and Szczecin-Swinoujście, achieved major importance, rivaling Hamburg and Trieste in the trade of central Europe. In 1950 of the total of 12,451,000 metric tons of exports overseas handled by Polish ports, Gdynia-Gdansk accounted for 7,894,000 and Szczecin-Swinoujście for 4,517,000, and of the 3,214,000 metric tons of imports from abroad, Gdynia-Gdansk for 2,214,000 and Szczecin-Swinoujście for 978,000. See also Table XI.

The rigorous export drive combined with rapid expansion of heavy industry, coming as it did immediately after a prolonged war, was borne at the expense of serious shortages in consumer goods of all kinds, including foodstuffs.

Transport and Communications.—Poland has been endowed with a general openness of topography, even in the south the mountain barrier is pierced, notably by the Moravian gate. The great northward-trending valleys have always provided routeways to the Baltic, the ancient seat of the Hanseatic league and the scene of a busy commerce down the ages. The havens of Gdansk and Szczecin (Danzig and Stettin, q.v.), with the advantages of estuary accommodation, tideless navigation and shelter from the open sea, are among the most favored in Europe. Counter to the general north-south trend run the east-west

TABLE XI.—Ships Entered in Polish Ports, 1950
(In thousands of net registered tons)

Origin	Tonnage	Origin	Tonnage
Swedish	110.6	German (Allied controlled)	48.9
Danish	104.4	British	14.1
Polish	91.1	United States	11.7
Finnish	81.2	Italian	11.1
Norwegian	76.8	Panama	11.1
Soviet	69.0	Others	14.6

valleys of the ancient ice-age rivers, occupied in part by tributaries of the main streams, they have been a factor in the situation of towns of central Poland and in the development of latitudinal communications. Finally, in the south, the comparatively favoured sub-Carpathian belt, with its rich mines, fertile soils, forest wealth and mountain passes, provided the channel of ancient routes running from southern Russia across southern Poland into western Germany and the Low Countries, cities like Lwow, Casow, and Wroclaw (Breslau) have for centuries commanded this old thoroughfare and been noted for their trade and commerce as well as their culture.

During periods of political tranquility, these natural influences exerted themselves freely. Unfortunately, the period of modern industrialization started not long after Poland had forfeited its independence, and enforced reorientations prevented the natural adjustment of the country's economy, the potentially valuable resources of the Silesia-Dabrowa basin were split between Prussia, Austria and Russia, and as the territory of Poland then lay on the borders of three great rivals, its resources were indifferently developed, its wealth drained in opposite directions.

The restored Poland inherited in 1918 three differing systems of communications, of which the Prussian was most highly developed, the Russian least so. The damage resulting from the Polish-Soviet war was very great, and the Russian railway system was mainly broad gauge. Roads were singularly ill provided, a disadvantage from which the country was still to suffer despite continuous road building between 1921 and 1939 and after 1945. Upper Silesia, the economic heart of Poland, remained divided, and, although Danzig formed a customs union with Poland, the Baltic was not freely accessible until after the opening of the new port of Gdynia.

The shift of frontiers in 1945 enriched the system of communications by bringing in the industrial areas of German Silesia and their outlet through the Oder valley, a region well supplied with railways, canals, rivers and roads. War damage was, however, higher than after World War I, and the period 1945-52 was occupied mainly with the work of reconstruction and the improvement of existing facilities. Destruction was computed at 40% of main railway tracks, 70% of large railway bridges, 42% of locomotives, 92% of passenger cars, 96% of freight cars, 30% of road surfaces, 100% of motor transport and 80% of boats and barges on inland waterways. Among the more spectacular achievements after 1945 were the driving of an east-west thoroughfare through Warsaw and the electrification of the Warsaw suburban line to Zyrardow. A beginning was also made on a Warsaw underground railway. In addition, Polish workshops were turning out rolling stock in large quantities for export to the Soviet Union. The railways crossing Poland from the Soviet Union to Germany took on a new significance, in view of the Soviet transit traffic in military and commercial goods, and the greatly increased volume of Polish-Soviet trade brought new importance to the broad-gauge interchange points

on the Polish eastern frontier

In view of the paucity of roads the inland waterways have always been of considerable importance to Poland. By far the greatest stretches of inland navigation are provided by the Vistula and Oder and their main tributaries. The low sandy banks, the fast-flowing streams and the tendency to flood after the spring thaw necessitated regulation and canalization. The interconnecting glacial valleys provided means of linking by short canals a whole series of east-west tributaries and so, eventually, the main river systems of Germany, Poland and the U.S.S.R. Thus the Oder and Royal canals (built in the 18th century, north and west of Pinsk) and the Augustow canal (built in 1825) joined the Vistula and Bug with the Niemen, Prępa and Dnieper, they were used between 1921 and 1939 for drifting Polesian timber westward but became part of Soviet territory. The Bydgoszcz (Bromberg) canal, built in 1914-16, was used for barge traffic between Germany and East Prussia, it linked Memel (Klaipėda) and Königsberg (Kalinigrad) in Soviet territory, with the Oder and central Germany by way of the sheltered lagoons and Royal canal (built in the canalized Nogai distributary of the Vistula and the rivers Brda and Noteć. This canal was linked in 1949 through Lake Gopło with the canalized river Warta, if this in turn were linked with Katowice, a prewar scheme for a north-south canal would have been realized. Another related scheme, an east-west canal joining Katowice with the headwaters of the Dniester through Cracow, the Vistula and the San, also failed to materialize, but the former German Upper Silesian field is served by a canal leading into the Oder, which makes Gliwice the most important inland port of post-1945 Poland. The much-publicized scheme for an Oder-Danube canal, originally scheduled to be completed by 1950 but still under discussion by 1951, was to take off from a point on the Gliwice canal, cross the Czech frontier at Bohumín and, by using the Morava, join the Danube near Devin.

TABLE XIII—Communications
(Lengths in kilometres)

Item	1934	1937	1947
Standard-gauge railways	16,652	18,102	20,040
Narrow-gauge railways	3,300	3,240	3,540
Navigable rivers and canals	3,200	3,120	3,979
Hard surfaced roads	97,530	60,788	90,005

The principle of state ownership of the standard-gauge railways, main roads and other chief means of communication, including tele-communications and radio, was carried over from the pre-1939 system, in addition those narrow-gauge railways still in private use were nationalized after 1945.

Table XII shows the development of railways, roads and canals in Poland between 1924 and 1947.

The Polish state-owned air lines, Lot, form part of the interlocking system of services linking the main cities of the Soviet bloc countries. The flights from Moscow to Moscow are restricted, however, to the Soviet air lines. In 1950 Lot maintained services to Paris, Brussels and

TABLE XIII—Air Traffic, 1948

Item	Lot	Foreign air lines
Flights	7,730	1,222
Miles flown	1,460,550	4,540
Passengers flown	77,522	6,960
Cargo carried (metric tons)	900.3	238.6

Copenhagen and to Amsterdam via Warsaw, in western Europe. In 1949 Lot's passenger traffic was 13,510,500 passenger-miles, as compared with 5,864,700 passenger-miles in 1938 (in prewar territory).

POLAR BEAR (*Ursus maritimus*) is a member of the family Ursidae, subfamily Ursinae, and is the largest of the bears. It is found in the Arctic region of the Northern Hemisphere, where it inhabits the tundra and coastal areas. The polar bear is a carnivore, feeding primarily on seals. It is a solitary animal, with only the females and their cubs associating. The polar bear is a powerful swimmer, capable of swimming long distances. It is a threatened species, with its population declining due to hunting and habitat loss.

POLAR BEAR (*Ursus maritimus*) is a member of the family Ursidae, subfamily Ursinae, and is the largest of the bears.

The aqueous solution to be analyzed is placed in a glass cell containing two electrodes. One electrode consists of a glass capillary tube (internal diameter about 0.05 mm. or 0.002 in.) from which mercury slowly flows downwards (dropping mercury electrode), and the other is a pool of mercury or other nonpolarizable electrode. The cell is connected in series with a galvanometer for measuring the flow of current, in an electrical circuit which contains a battery, or other source of direct current, and a rheostat by means of which the voltage applied to the electrodes can be varied from zero up to about two volts. Usually with the dropping mercury electrode connected to the negative side of the polarizing voltage, the voltage is increased by small increments and the corresponding current is observed on the galvanometer. The current is very small until the applied voltage is increased to a value large enough to cause the substance being determined to be reduced at the dropping mercury electrode. The current increases rapidly at first as the applied voltage is increased above this critical value, but gradually attains a limiting value and remains more or less constant as the voltage is increased further. The critical voltage required to cause the rapid increase in current is characteristic of, and serves to identify, the substance being reduced (qualitative analysis). Under proper conditions the constant limiting current is governed by the rate of diffusion of the reducible substance up to the surface of the mercury drops, and its magnitude is a measure of the concentration of the reducible substance (quantitative analysis).

Limiting currents also result from the oxidation of certain easily oxidized substances at the dropping electrode.

In 1925 J. Heyrovský and M. Shkita invented an instrument called the polarograph which automatically applies an increasing voltage to the dropping electrode cell and photographically records the resulting current-voltage curve. Curves thus recorded are called polarograms.

When the solution contains several substances that are reduced or oxidized at different voltages, the polarogram shows a separate current increase (polarographic wave) and limiting current for each. The method is thus capable of detecting and determining several substances simultaneously.

The method is applicable to relatively small concentrations of reducible or oxidizable substances (10^{-5} up to about 0.01 moles per litre, or approximately 1 to 1,000 parts per 1,000,000).

The majority of the chemical elements can be determined by polarographic analysis. The method is applicable to the analysis of alloys and other metallic products, and various inorganic compounds.

Polarography is also used to determine many types of organic compounds, and to study chemical equilibria and rates of reactions in solutions.

POLAR REGIONS: see ANTARCTIC REGIONS, ARCTIC REGIONS.

POLDER, the Dutch name for a piece of artificially drained low-lying land reclaimed from the sea or other water and protected by high embankments (see HOLLAND).

POLE (FAMILY) The family of the Poles, earls and dukes of Suffolk, which, but for Richard III's defeat at Bosworth, might have given the next king to England, had its origin in a house of merchants at Kingston-upon-Hull. The Poles were among the first English peers whose fortunes had been founded upon riches gained in trade.

William atte Pole (d. c. 1339), a merchant of Ravensrode, settled in Hull. His sons, Sir Richard and Sir William atte Pole, were both famous for their wealth.

Sir Richard (d. 1345), the king's butler in 1327, moved to London, and is styled a London citizen in his will. The male line of this, the elder branch of the Poles, failed with a grandson, John Pole, whose daughter was Joan, lady of Cobham, the Kentish heiress, whose fourth husband was Sir John Oldcastle the Lollard.

Sir William atte Pole (d. 1366), the second son of William, joined his brother in advancing large sums to the government

while keeping safely apart from politics. The first mayor of Hull, he sat for Hull in five parliaments, and was advanced to be knight banneret and a baron of the exchequer. He was counted "second to no merchant in England," but after his time his descendants left the counting-house, his four sons all serving in the French wars. The eldest son, MICHAEL POLE, 1st earl of Suffolk, who had fought under the Black Prince and John of Gaunt, became (1383) chancellor of England. In 1385 he was created earl of Suffolk, a grant from the Crown giving him the castle and honour of Eye with other East Anglian lands formerly held by the Ufford earls. In 1386 the opposition, led by Gloucester, the king's uncle, pulled him down. He was dismissed from his chancellorship, impeached, and convicted. Richard was forced to send his minister into ward at Windsor until the parliament was dissolved, when Suffolk once more appeared as the leader of the king's party. But the opposition was insistent, and Suffolk fled over sea to Calais. He died an exile in Paris in 1389.

The exile's son Michael, 2nd earl, was restored in 1397, died of dysentery at Harfeur, and his son Michael was killed at Agincourt. Michael was succeeded as 4th earl by his brother William (See SUFFOLK, WILLIAM DE LA POLE, DUKE OF).

John Pole (1442-1491), the only son of the 4th earl, should have succeeded to the dukedom, his father having died unattained. But the honours were apparently regarded as forfeited, and the dukedom was formally restored to the boy in 1455, the earldom of Pembroke being allowed to lapse. He married King Edward IV's sister Elizabeth. The marriage confirmed him a partisan of the White Rose. Before he was of age he was steward of England at his brother-in-law's crowning, and at Queen Elizabeth's crowning he bore her sceptre. Having held many offices under Edward IV he was ready to bear a sceptre at Richard's coronation, and, after Bosworth, to swear fealty to the Tudor dynasty and to bear another sceptre for another Queen Elizabeth. He died in 1491, having safely kept his lands, his dukedom, and his head through perilous years. (See SUFFOLK, EARLS AND DUKES OF AND POLE, RICHARD DE LA.)

Another family of the name of Pole, having no kinship with the house of Suffolk, owed their advancement and their fall to a match with a princess of the royal house. Sir Richard Pole, a Buckinghamshire knight, was the son of Geoffrey Pole, a squire whose wife, Edith St. John, was sister of the half-blood to the mother of Henry VII. About 1490 or 1491 he married the Lady Margaret, daughter of George, duke of Clarence. He died in 1505, and in 1513 King Henry VIII. created the widow countess of Salisbury, as some amends for the judicial murder of her brother, the Earl of Warwick. Four years later, the barony of Montague was revived for her eldest son Henry. Until the king's marriage with Anne Boleyn, the countess of Salisbury was governess of her godchild, the Lady Mary. When her son, the famous Cardinal Pole, published his *Pro ecclesiasticæ unitatis defensione* the whole family fell under the displeasure of the king, who resolved to make an end of them. The Lord Montague was the first victim, beheaded in 1539 on a charge of treasonable conversations, on evidence of his brother, Sir Geoffrey Pole. In 1541 the aged countess, attainted with her son Montague, was also executed. Sir Geoffrey Pole fled the country, and joined the cardinal in exile. He returned with him at Mary's accession, both dying in 1558. His sons Arthur and Edmund, taken in 1562 as plotters against Queen Elizabeth, were committed to the Tower of London, where they died after eight years of imprisonment.

POLE, REGINALD (1500-1558), English cardinal and archbishop of Canterbury, born at Stouton Castle, Staffordshire, was the third son of Sir Richard Pole and Margaret, countess of Salisbury, niece of Edward IV. Intended for the Church, he was sent for five years to the grammar school founded by Colet at Sheen. Here he had Linacre and William Latimer as teachers. In his thirteenth year he went to Magdalen College, Oxford, and two years after took his degree in arts. In 1517 Henry VIII. appointed

his young kinsman to a prebend in Salisbury, and soon afterwards to the deaneries of Wimborne and Exeter. He was a friend of Sir Thomas More, who says that Pole was as learned as he was noble and as virtuous as he was learned. In 1519, at the king's expense, he went to Padua, the Athens of Europe, according to Erasmus; and there, where Colet and Cuthbert Tunstall had also been educated, he came into contact with the choicest minds of the later Italian Renaissance, so forming his friendships.

In 1525 he went to Rome for the Jubilee, and two years after returned to England and was initiated by Thomas Cromwell into the mysteries of statesmanship, that master telling him that the main point consisted in discovering and following the will of princes, who are not bound by the ordinary code of honour. When the divorce question arose, Pole seems at first to have been in its favour. He probably took the same view that Wolsey had, viz. that the dispensation of Julius II was insufficient, as of two existing impediments only one had been dispensed. When, however, the king raised the theological argument which ended in disaster, Pole could not accept it, and, after the failure of Campeggio's mission, when the king asked him for his opinion, he excused himself on the score of inexperience, but went by Henry's order to Paris (1530) to obtain the judgment of the Sorbonne, insisting on the presence of a colleague to do the necessary business. On his return to England he spoke strongly against the project to the king, who sought to propitiate him by the offer of the sees of York or Winchester, which were kept vacant for ten months for his acceptance. There was a stormy interview at York Place, but eventually Henry told him to put into writing his reasons against the divorce. This was done, and, recognizing the difficulties of the situation, the king gave him leave to travel abroad, and allowed him still to retain his revenues as dean of Exeter. In 1535, which saw by the deaths of Bishop Fisher and Sir Thomas More a change in Henry's policy, Pole received orders to send a formal opinion on the royal supremacy, and the king promised to find him suitable employment in England, even if the opinion were an adverse one. The parting of the ways had been reached. Pole's reply, which took a year to write, and was afterwards published with additions under the title *Pro ecclesiasticæ unitatis defensione*, was sent to England (May 25, 1536), meant for the king's eye alone. It contained a severe attack upon the royal policy, and a warning of temporal punishment at the hands of the emperor and the king of France if Henry did not repent of his cruelties and return to the Church. Pole was again summoned to return to England to explain himself, but declined until he could do so with honour and safety, but he was on the point of going at all risks, when he heard from his mother and brother that the whole family would suffer if he remained obstinate.

Paul III., who had prepared a bull of excommunication and deposition against Henry, summoned Pole to Rome in October, and two months after created him cardinal. In January 1537 he received a sharp letter of rebuke from the king's council, together with the suggestion that the differences might be discussed with royal deputies either in France or Flanders, provided that Pole would attend without being commissioned by any one. He replied that he was willing and had the pope's leave to meet any deputies anywhere. Paul III. in the early spring of that year named him legate *a latere* to Charles V. and Francis I., to secure their assistance in enforcing the bull by helping a projected rising in England against Henry's tyranny. The mission failed, owing to the mutual jealousy of the sovereigns. Francis feared to allow his presence in France, and Pole passed over to Flanders, and awaited in vain royal deputies. In August 1537 the cardinal returned to Rome. There he was appointed to the commission established by Paul III. for considering the reforms necessary for the church and Roman curia. The report *Consilium delectorum cardinalium* is, in its plain-spoken directness, one of the most noteworthy documents of the history of the period. Towards the end of 1539, after Henry had destroyed the shrine of St. Thomas Becket, another attempt was made to launch the bull of deposition, and Pole again was sent to urge Charles V. to assist. Once more his efforts were in vain, and he retired to his friend Sadoletto at Carpentras. As Pole had escaped Henry's power the royal ven-

gence fell on his mother, who was executed on May 27, 1541.

On Aug. 21, 1541, the cardinal was appointed legate at Viterbo, and for a few years passed a happy and congenial life amid the friends that gathered round him. Here he came into close relations with Vittoria Colonna, Contarini, Sadoleto, Bembo, Morone, Marco Antonio, Flaminio, and other scholars and leaders of thought, and many of the questions raised by the Reformation in Germany were eagerly discussed in the circle of Viterbo. The burning question of the day, justification by faith, was a special subject of discussion. Pole's own attitude to the question of justification by faith is given by Vittoria Colonna, to whom he said that she ought to set herself to believe as though she must be saved by faith alone and to act as though she must be saved by works alone. In the excited temper of the times any defender of justification by faith was looked upon by the old school as heretical, and Pole, with the circle at Viterbo, was denounced to the Inquisition. Though the process went on from the pontificate of Paul III to that of Paul IV, nothing was done against the cardinal until the time of the latter pope.¹

While at Viterbo his rule was firm but mild, and he regained many heretics, such as his friend Flaminio, by patience and kindness, to a reconsideration of their opinions. During this time also he was still engaged in furthering a proposed armed expedition to Scotland and the papal party, and in 1545 he was again asking help from Charles V. But the Council of Trent (q.v.) required all his attention. In 1542 he had been appointed one of the presiding legates and had written in preparation his work *De concilio*, and now in 1545, after a brief visit to Rome, he went secretly, on account of fear of assassination by Henry's agents, to Trent, where he arrived on May 4, 1545. At the council he advocated that dogmatic decrees should go together with those on reform as affording the only stable foundation. His views on the subject of original sin, akin as it is to that of justification, were accepted and embodied in the decree. He was present when the latter subject was introduced, and he entreated the fathers to study the subject well before committing themselves to a decision. On June 28, 1546, he left Trent on account of ill-health and went to Padua. While he was there frequent communications passed between him and the council and the draft of the decree on justification was sent to him. His suggestions and amendments were accepted, and the decree embodies the doctrines that Pole had always held of justification by a living faith which showed itself in good works. This effectually disproves the story that he left the council so as to avoid taking part in an adverse decree.

On the death of Henry (Jan. 28, 1547), Pole was excepted from the general pardon. At the conclave of 1549 Pole received two-thirds of the votes, but by a delay, he lost the election and Julius III succeeded. He then retired to Magazzano on the Lake of Garda and occupied himself in editing his book *Pro unitate ecclesiae*, with an intended dedication to Edward VI.

On the accession of Mary he was appointed legate to the new queen, and began his negotiations. But he was still under attack, and the temper of England was not yet ripe for the presence of a cardinal. The project of the queen's marriage was also an obstacle. A marriage between her and Pole, who was then only a deacon, was proposed by some, but this was opposed by the emperor. The marriage with Philip, of which Pole did not approve, having taken place (July 25, 1554), and Rome yielding on the practical difficulties of the lay holders of Church lands, Pole was allowed to return to England as cardinal. On his landing he was informed that the attainder had been reversed, and he was received with joy by Mary and Philip. He proceeded to parliament and there absolved the kingdom and accepted in the pope's name the demands respecting ecclesiastical property. He rectified the canonical position of those who had been ordained or consecrated since the breach with Rome. Those ordained in schism, indeed, but according to the old Catholic rite, were absolved from their irregularity, and, receiving penance, were reinstated, those

ordained under the new rite were simply regarded as laymen and dismissed without penance or absolution. Pole was not responsible for the cruel persecution by which the reign was disfigured. On Nov. 4, 1555, Pole opened, in the chapel royal at Westminster, a legate synod, consisting of the united convocations of the two provinces, for the purpose of laying the foundations of wise and solid reforms. In the *Reformatio Angliae* which he brought out in 1556, based on his Legatine Constitutions of 1555, he ordered that every cathedral church should have its seminary. He also ordered that the Catechism of Caranza, who, like him, was to suffer from the Inquisition for this very book, should be translated into English for the use of the laity. On Cranmer's deprivation, Pole became archbishop of Canterbury, and, having been ordained priest two days before, he was consecrated on March 22, 1556, the day after Cranmer suffered at Oxford. But the clouds began to gather round him. His personal enemy Caraffa had become pope under the name of Paul IV and was biding his time. When Rome quarrelled with Spain, and France, on behalf of the pope, took up arms, England could no longer observe neutrality. Paul IV deprived Pole of his power both as legate *altrius* and *legatus natus* as archbishop of Canterbury (June 14, 1557); he also reconstituted the process of the Inquisition against the cardinal, and summoned him to Rome to answer to the crime of heresies imputed to him. Mary, who had been warned by her ambassador to the pope that prison awaited Pole, prevented the breve ordering the cardinal to proceed to Rome from being delivered, and so Pole remained in England. Broken down as much by the blow as by ill-health the cardinal died at Lambeth on Nov. 17, 1558, twelve hours after Mary's death and under the unmerited disgrace of the papacy in defence of which he had spent his life. He was buried at Canterbury near the site of the shrine of St. Thomas Becket.

The chief sources for Pole's biography are his life written in Italian by his secretary Becattelli, which was translated into Latin by Andrew Dudith as *Vita Poli cardinalis* (Venice, 1563), and his letters (*Epistolae Reginaldi Poli*) edited by Girolamo Quirini and published in 5 volumes (Brescia, 1744-57), a new edition of which is in preparation at Rome with additions from the Vatican Archives. See also the State Papers (foreign and domestic) of Henry VIII., Edward VI. and Mary, the Spanish and Venetian State Papers, vol. 1 of A. Thiemer's *Acta genuina S.S. Documenti Caecili Tridentini* (1874), the *Compendio dei processi del santo ufficio di Roma da Paolo III a Paolo IV* (Società romana di storia patria, Archivio, n. 261 seq.); T. Philipp's *History of the Life of R. Pole* (Oxford, 1764-67); Athanasius Zimmermann, S.J., *Kardinal Pole sein Leben und seine Schriften* (Regensburg, 1893); Martin Haile, *Life of Reginald Pole* (1910), and F. G. Lee, *Reginald Pole*.

POLE, RICHARD DE LA (d. 1525), pretender to the English crown, was the fifth son of John de la Pole (1442-1491), and duke of Suffolk, and Elizabeth, second daughter of Richard, duke of York and sister of Edward IV. His eldest brother John de la Pole, earl of Lincoln (c. 1464-1487), is said to have been named heir to the throne by his uncle Richard III., who gave him a pension and the reversion of the estates of Lady Margaret Beaufort. On the accession of Henry VII., however, Lincoln took the oath of allegiance, but in 1487 he joined the rebellion of Lambert Simnel, and was killed at the battle of Stoke. The second brother Edmund (c. 1472-1513) succeeded his father while still in his minority. His estates suffered under the attainder of his brother, and he was compelled to pay large sums to Henry VII. for the recovery of part of the forfeited lands, and also to exchange his title of duke for that of earl. For his negotiations with the German King Maximilian in Tirol, Henry seized his brother William de la Pole, with four other Yorkist noblemen. Two of them, Sir James Tyrell and Sir John Wyndham, were executed, William de la Pole was imprisoned and Suffolk outlawed. Then in July 1502 Henry concluded a treaty with Maximilian by which the king bound himself not to countenance English rebels. Presently Suffolk fell into the hands of Philip, king of Castile, who imprisoned him at Namur, and in 1506 surrendered him to Henry VII. on condition that his life was spared. He remained a prisoner until 1513, when he was beheaded at the time his brother Richard took up arms with the French king.

Richard de la Pole joined Edmund abroad in 1504, and remained at Aix as surety for his elder brother's debts. The creditors

¹Within the institution of the Inquisition his name continued to be regarded as that of a heretic and misleader of others, as is proved by the mass of evidence accumulated against him in the *Compendium Inquisitionum* (v. *archivio della società di storia patria*, Rome, 1880).

threatened to surrender him to Henry VII, but, more fortunate than his brother, he found a refuge with King Ladislas VI of Hungary. He was excepted from the general pardon proclaimed at the accession of Henry VIII, and when Louis XII, went to war with England in 1512 he recognized Pole's pretensions to the English crown, and gave him a command in the French army. In 1513, after the execution of Edmund, he assumed the title of earl of Suffolk. In 1514 he was given 12,000 German mercenaries ostensibly for the defence of Brittany, but really for an invasion of England. These he led to St. Malo, but the conclusion of peace with England prevented their embarkation. Pole was required to leave France, and he established himself at Metz, in Lorraine, and built a palace at La Haute Pierre, near St. Simphorien. He had numerous interviews with Francis I, and in 1523 he was permitted, in concert with John Stewart, duke of Albany, the Scottish regent, to arrange an invasion of England, which was never carried out. He was with Francis I at Pavia and was killed on the field on Feb. 24, 1525, so ending the male line.

See *Letters and Papers Illustrative of the Reigns of Richard III. and Henry VII.*, edited by J. Gardner (3 vols., "Rolls Series," 24, 1861), *Calendar of Letters and Papers, Foreign and Domestic, of the Reign of Henry VIII.*; and Sir William Dugdale, *The Baronage of England* (London, 1675).

POLE, WILLIAM (1814–1900), English engineer, was born at Birmingham on April 22, 1814. He spent some years as a professor of engineering in Bombay, returning to England in 1848, and in 1859 was appointed to the chair of civil engineering in University College, London. He was secretary to the Royal Commission on Railways (1865–67); the duke of Richmond's Commission on London Water (1867–69), also taking part in the proceedings for establishing a constant supply; the Royal Commission on the Disposal of London Sewage (1882–84), and the departmental committee on the science museums at South Kensington in 1885. In 1871 he was appointed consulting engineer in London to the Japanese Government. He was elected F.R.S. in 1861 for some investigations into colour-blindness. Music was also one of his chief interests, and in 1867 he took his doctor's degree, acting for many years as examiner for musical degrees at the University of London. In 1879 he published his *Philosophy of Music*. He died on Dec. 30, 1900.

POLE. For pole star see **POLE STAR**, for polar regions see **ARCTIC REGIONS**; **ANTARCTIC REGIONS**; for magnetic poles see **MAGNETISM**. See also **BATTERY**, **CRYSTALLOGRAPHY**, **GEODESY**, **GEOMETRY**, **POLE VAULTING**, **SPHERE**.

POLE AND POLAR, in mathematics. If from a point P outside a circle the two tangents to the circle be drawn, the line joining the points of contact is called the *polar* of the point P , and P is called the *pole* of the secant line. If P is on the circle, the two tangents coincide and the polar of P is the single tangent at P . For Q , a point inside the circle, draw two secants to the circle through it. The line joining their poles is called the polar of Q . If the polar of P passes through Q , the polar of Q passes through P . The same principle applies to any conic. In space there is a corresponding theory of points and polar planes as to a sphere or any fixed quadric surface. The idea is due to Brianchon, who first applied it in 1806, but it was developed by Poncelet, and presented in final form in 1820. More recently the concept has been extended to other curves and surfaces, and to other configurations.

POLECAT, the name given to any member of the Musteline subgenus *Putorius* (see **CARNIVORA**). Polecats are confined to the northern hemisphere. The European polecat, *Mustela putorius*, inhabits the whole central and northern parts of the continent, though now rare in Britain. It is well known in its domesticated, albino variety as the ferret (*q.v.*). The wild polecat is dark brown above and black below, the face being variegated with white. The fur is long, coarse, and of little commercial value. It is more powerful than the marten (*q.v.*) but less active, and rare-

ly climbs trees. Its food consists of small mammals and any birds it can catch, especially poultry. It also eats snakes, lizards, frogs, fish and eggs. It is extremely blood-thirsty and hunts at night. From three to eight young are produced in April or May, after a two months' gestation. It is very tenacious of life and has a feld smell.

It is replaced in north Asia by an allied species, *M. ermineum*, and on the central plateau of the United States by a third form, *M. nigripes*, with creamy-yellow fur, brown legs and black feet and tail. A related genus, *Forsia*, whose fur is white marbled with reddish spots above, extends from east Poland to Afghanistan. All these animals resemble *M. putorius* in habits.

POLENTA, DA, the name of a castle in Romagna, from which came the noble and ancient Italian family of Da Polenta. The founder of the house is said to have been Guido, surnamed l'Antico or the Elder, who wielded great authority in Ravenna in the 13th century. His grandson Guido Novello upheld the power of the house and was also *capitano del popolo* at Bologna; he was overthrown in 1322 and died in 1323. In 1321 he gave hospitality to the poet Dante, who immortalized the tragic history of Guido's daughter Francesca, unhappily married to Malatesta, lord of Rimini, in an episode of the *Inferno*. Guido's kinsman Ostasio I was lord of Cervia and Ravenna from 1322 to 1329, and, after being recognized as a vassal of the Holy See, again became independent and went over to the house of Este, whom he served faithfully in their struggles with the Church until his death in 1346. His son Bernardino, who succeeded him as lord of Ravenna in 1346, was deposed in 1347 by his brothers, Pandolfo and Lamberto II, but was reinstated a few months later and ruled until his death in 1359; he was famous for his profligacy and cruelty. His son Guido III ruled more mildly and died in 1390. Then followed Ostasio II (d. 1396), Obizzo (d. 1431), Pietro (d. 1404), Aldobrandino (d. 1406), all sons of Guido III. Ostasio III (or V), son of Obizzo, was at first allied with the Venetians, later he went over to the Milanese, and, although he again joined the Venetians, the latter never forgave his intrigue with their enemies, and in 1441 they deprived him of his dominions. He died in a monastery in 1447.

POLESIE (*i.e.*, "along the forest"), the largest and most sparsely populated province of Poland. Area, 14,219 sq. mi. Pop. (1931) 1,131,000. The bulk of the inhabitants are Ruthenians—the so-called Polesians or Pinchiks, forming a special branch of the Ukrainian nationality, and belonging to the Orthodox Eastern Church. Polesie was taken by the U.S.S.R. in 1939 and by Germany in 1941.

Polesie forms an eastward extension of the central Polish plain sloping up to the northern highlands and the plateau of Podolia. It forms the basin of the Prypyet, a tributary of the Dnieper, into which flow numerous slow rivers from the Lithuanian forests of the north, and from the uplands of the south. The falls of the Lower Dnieper hinder the drainage of Polesie, and the deepening of the channel of the Dnieper tends to dry up the Pinski marshes. In spring the whole country is flooded and has the appearance of a sea. In reality it consists partly of marshes and lakes, partly of damp meadows with islands of clay or sand, on which most of the villages are built. In such a dreary plain the main feature is the vegetation, which consists of wide pine forests on the sand or on the swamps, with invading firs from the north, of mixed forests and birch groves, and of damp meadows grown with grasses, reeds and stunted willows. It is the only remaining home of the beaver in Poland, and the elk is still found there. The inhabitants maintain a precarious existence mainly by fishing and hunting. With few horses, there is a special breed of cattle.

Polesie originally formed the early Russian principality of Turov or Pinsk. Conquered by the Lithuanians in 1320, it became, after the union with Poland in 1569, the province of Brest Litovsk. The north-west portion formed part of the estates of the great Polish magnates, the Radziwills and Sapiehas. Wolczyn was the seat of the Czartoryski family. The chief towns are Brest Litovsk, pop. (1931) 50,733, the capital, Pinsk, the seat of an ancient Orthodox bishopric, Kobryn, Kamenets Litovsk and Luninets, a junction of the two railways which traverse the marshes.

POLE STAR or **POLARIS**, the (naked-eye) star nearest the pole in the northern hemisphere (*See ASTRONOMY Spherical Astronomy*) It is the brightest star in the constellation Ursa Minor (γ), hence its Bayer equivalent, α Ursae Minoris. Polaris is a yellow supergiant star located at a distance of the order of 500 light-years from the sun.

POLE VAULTING, the art of jumping over an obstacle with the aid of a pole. Originally a means of clearing objects, such as ditches, brooks and fences, pole vaulting for height, clearing a bar supported by two uprights set not less than 12 ft apart, became a competitive athletic sport. Requirements of the athlete are technical knowledge and an understanding of the physics of the sport, a high degree of co-ordination, timing, speed and gymnastic strength. Up to the end of the '80s all the world's record holders came from the small town of Ulverston, in Lancashire, England. It was not really "pole vaulting" but rather "pole climbing." This method was barred. The pole used is generally bamboo, sometimes aluminum, and the spike which was formerly used in the end of the pole has been abandoned. A sideways is sunk in the ground, the back of which is placed directly below the crossbar. Into this sideways the pole is thrust. A soft pit, generally of sawdust, is provided for the vaulter for landing.

The modern pole vaulter approaches the take-off with great speed, carrying the pole with his hands about 2½ ft apart. As the stride, next before the spring, is completed, he performs the shift, which consists of advancing the pole toward the sideways (which is known as the advance) and at the same time allowing the lower hand to slip up the pole until it reaches the upper hand, and raising both hands as high above his head as possible before leaving the ground. He is thus enabled to exert the full pulling power of both arms to raise his body and help the swing-up of his legs. There are two factors the pole vaulter bears in mind—one is height and the other is carry. Height gives him the elevation, and carry takes him across the bar. It is noteworthy that this trick, perfected by Raymond G. Clapp of Yale university (U.S.A.), raised the world's record in 1898 to 11 ft 10½ in., whereas, not employing the manual shift, H. H. Baxter of the New York Athletic club (U.S.A.) in 1883 vaulted 11 ft ½ in.

The modern pole vaulter should have these qualifications: height (the taller man has a distinct advantage), speed, gymnastic strength and years of practice to master the modern technique. The modern pole vaulter generally uses the following technique:

A long run of approximately 150 ft, great speed down the runway and exact timing when the shift takes place, so that his hands are extended high above his head at the minute of the take-off. He then runs off the ground (he does not jump) leaving his body hanging by the hands as long as possible, not pulling too soon. He then lets his legs swing upward and to the side of the pole. The athlete's feet should reach a point well above the crossbar, in an attempt to actually make a handstand. At this stage the vaulter shoots his legs high above the crossbar by means of a strong arm pull on the pole. He next turns his body face downward and converts his pulling force into a pushing force. The bar lies in the concavity of the stomach, so that his feet are on one side and his head and shoulders are on the other side. The athlete finally carries his body across the crossbar, by what is known as the carry, which is the speed he has acquired from his run. Adoption of the bamboo pole, used with the modern technique, added approximately a foot to the records. In 1908, four Yale men (Campbell, Nelson, Dray and Gilbert) won all the places in the intercollegiate games at Philadelphia, using a bamboo pole. Astounding improvements in performance are indicated as follows: (1) H. H. Baxter (New York Athletic club), in 1883, 11 ft ½ in. (using old style), the first man to vault over 11 ft; (2) Norman E. Dole, 1904 world's record, 12 ft 10½ in., the first man to vault over 12 ft; (3) Robert A. Gardner (Yale university), at the I.C.A.A.A. games in 1912, 13 ft 1 in., the first man to vault over 13 ft; (4) Sabin W. Carr (Yale university), at the I.C.A.A.A. games in 1927, 14 ft, the first man to vault 14 ft; (5) Cornelius Warmerdam (Olympic club), at Berkeley, Calif., in 1940, 15 ft, the first man to vault 15 ft; (6) Cornelius Warmerdam, world's indoor record, at Chicago, 1943, 15 ft 8½ in.,

and world's outdoor record, at Modesto, Calif., in 1942, 15 ft 7½ in. (A C G)

POLIANTHES, one of the florists' flowers, commonly called tuberose, probably derived from *P. tuberosa*, which is unknown as a wild plant (*See TUBEROSE*).

POLICE. As now generally employed, the term police means the maintenance of public order and the protection of persons and property from the hazards of public accidents and the commission of unlawful acts. Earlier meanings included such limited activities as street paving and lighting, or scavenging and sanitation, as well as applications broad enough to comprehend the entire range of the domestic policies of government.

Authoritarian states set up secret political police organizations that operate independently of the regular civil police establishments. Political police are always highly centralized agencies. The Nazi *gestapo* and *schutzstaffel*, the Tsarist *ochrana*, the Soviet *cheka*, *ogpu* and *NKVD* and Mussolini's *ovra* all had common characteristics sharply distinguishing them from other civil police. Their governments, among others, came to be known as "police states." Democratic governments are also impelled to establish their security from subversive elements, but they do not hesitate to entrust it primarily to police forces charged with law enforcement in general. Popular governments permit much local autonomy in police administration while authoritarian states tend to centralize police control, but the intrusion of other factors also may produce centralized police control even under democratic patterns. England, Wales and Scotland have scores of local police forces, whereas the Republic of Ireland and the government of Northern Ireland each maintain but a single police establishment. Belgium has dual police systems for the national and local levels with municipal forces resting upon almost complete local autonomy, whereas in Denmark all police activities are administered by functionaries of the crown. Similar contrasts characterize the police arrangements of France and the Netherlands and of Sweden and Norway. In the United States and Canada, national and state (or provincial) police lie parallel to local police systems.

Modern police administration has five major aspects: uniformed patrol, criminal investigation (detection of criminals), traffic regulation, special measures for controlling commercialized vice (liquor, narcotics, prostitution and gambling) and procedures and facilities for dealing with women offenders and juvenile delinquents. The latter are often staffed by police women.

United States—Strictly speaking, the United States has no police system. It has about 40,000 police jurisdictions represented by the federal government, the 48 states, the sheriffs and deputy sheriffs of 3,000 counties, a handful of county police forces independent of the sheriffs' offices, the police of 1,000 cities and occasional constables in more than 20,000 townships, magisterial districts or county districts, together with other minor forces in 15,000 villages, boroughs and incorporated towns. In addition, there are a number of special districts concerned with the patrol of parks, parkways, tunnels, bridges and aqueducts. In short, police administration follows the jurisdiction of the civil governments, whether federal, state or local. This produces serious internal strains since in a given area there may be as many as five or six levels of police administration. It also unduly complicates the task of co-ordinating investigations and other police activities. Central clearinghouses for crime records, criminal identification and police training and the vast interstate networks of police teletype and radio serve in part to overcome some of the more flagrant defects, however.

The total numerical strength of all full-time and part-time police in the service of these many jurisdictions was about 175,000 at mid-20th century. The well-defined trend is away from part-time police, particularly the township constables and deputy sheriffs, but when such as these are found to be inadequate, state and local governments still are prone to create new and additional police bodies without troubling to dispose of the outworn protective agencies. Multiple overlapping of police jurisdiction is thereby produced with occasional conflicts of interest among separate and distinct police forces operating independently within a given area.

Local police agencies range in size from only one or two part-time employees to the highly developed force of 20,000 men in New York City. The ratios of police to population generally are highest in the largest cities and decline by graduated steps. Thus, in cities of more than 250,000 population the number of police per thousand of population was 2.41 in 1949, while in places of less than 10,000 population, the ratio was only 1.35.

Similar variations appear when geographic location is considered. For cities and other urban places the Pacific coast has the highest police ratios. Cities with the lowest ratios of police to population are most commonly found in the central states.

The general effect of such relationships to size and location is that police strength is not only disproportionately greater in those parts of the country having the larger urban centres, but it is in large degree actually concentrated in the big cities. Thus, in 3,275 urban places where 139,000 policemen were employed in 1949, more than half (72,000) were in 37 cities of more than 250,000 population.

The inherent weakness of the smallest police establishments and the abdication of police authority by many rural functionaries combined to produce inadequate police defenses throughout most of the U.S. countryside. For many years this condition was ignored, but the advent of the motor age brought with it so many problems of crime control and traffic regulation that the ancient sheriff-constable system was quickly overwhelmed. A new type of police agency thereupon emerged—one destined to have a far-reaching influence upon the future development of police in the United States and upon the ultimate distribution of functions among local and state governments. The 19th century witnessed several limited and tentative experiments in state police administration—in Texas, Massachusetts and Connecticut—but it was not until 1905 that Pennsylvania established its state police force, and when New York and other large commonwealths followed at about the time of World War I, and shortly thereafter, success of the state police idea was assured. Because these agencies were in fact wholly new, they did not inherit the old U.S. police tradition, parts of which were thoroughly bad. Furthermore they were able to experiment with new devices for selection, training, promotion and discipline.

By the time of World War II every state had acquired a police agency of its own. Some of these were rudimentary in conception and limited in both authority and numbers. Some were charged merely with the patrol of state highways for the single purpose of traffic law enforcement. Others sprang into existence with broad enforcement powers exercised throughout great and populous states but especially in the rural areas where local policing was least adequate. Without exception, state police forces represented a break with the past and with the tradition of local autonomy in police management. But their numbers were nowhere great—Pennsylvania with 1,600 state troopers at mid-20th century maintained the largest single force—and all told they did not total more than 10,000 in the service of the 48 states. Moreover, the establishment of state police was not accompanied by any large-scale abandonment of the outworn and outdated local police units.

The federal government also was drawn more and more into the police field, because it could not be expected indefinitely to entrust the enforcement of many federal statutes to local and state police bodies. The stresses of the Civil War brought several rudimentary investigative agencies into existence while an expanding field of federal regulation encouraged the development of others. Forty federal agencies were performing some part of the police function by 1950. In all but a mere handful of these, law enforcement was either auxiliary to other administrative activities or was performed within a narrowly restricted area or involved in the conduct of military or naval operations.

General police jurisdiction at the national level is exercised only by the Federal Bureau of Investigation, popularly known as the FBI. This select corps of criminal investigators has performed its various law-enforcement functions in such fashion as to encourage repeated additions to the scope of its responsibilities. Extensive crime laboratories and a uniform system of crime

reporting for all jurisdictions in the United States and its possessions serve to round out the central services performed by the FBI for state and local law-enforcement agencies.

In a special category are the police patrols maintained by such federal agencies as the Tennessee Valley authority, while the police department of Washington, D.C., is wholly unique in the U.S. scene. Commissioners appointed by the president administer the governmental affairs of this federal district and accordingly are responsible for law enforcement within its boundaries.

A prominent feature in a typical police force in the United States is the wealth of equipment, particularly for transportation and communication. Whatever the shortcomings of the various federal, state and local police systems, there can be no doubt that in the use of mechanical aids they lead the world by a wide margin. Also notable is the steady rise in police salary scales after 1910 and the increasing adoption of retirement systems, some of which are established on a sound actuarial basis.

Great Britain.—Modern police administration in Great Britain stems from the establishment in 1829 of the metropolitan police in the sprawling urban and suburban area surrounding the City of London. This extends in a wide circle of 700 sq mi, most of it lying within a radius of 15 mi from Charing Cross as a centre. The ancient City, however, is only 1 sq mi in area, is of limited resident population but of great wealth and importance and has never been a part of the metropolitan police district. With this exception, the metropolitan police district embraces all of London and Middlesex counties and parts of Surrey, Essex, Kent and Hertford, the whole including several score municipal and county boroughs.

Headquarters of the metropolitan force are at New Scotland Yard in the borough of Westminster on the Thames embankment—close by the offices of the national government and the seat of empire in Whitehall. The police commissioner of the metropolis is appointed by the crown, with the home office occupying the position of responsible police authority in all metropolitan police matters. The home secretary exercises direct control over this critically important agency for law enforcement in the nation's capital.

The commissioner of the City of London police is chosen by the mayor and aldermen, while in other cities and boroughs having their own police establishments, the watch committee of the city or borough council appoints the chief constable in each instance. Each county constabulary is under the control of a standing joint committee consisting of specially designated members of the county council and justices of the peace (quarter sessions). This committee selects the chief constable, but in counties, cities and boroughs alike, the choice of a chief constable must be ratified by the home office.

The early county constabularies were created around 1840, primarily for the protection of rural areas, but many now are also charged with responsibility for policing cities and boroughs, some of them of considerable size. This process of consolidation had been going on for many years and was speeded up greatly by the exigencies of World War II. Further absorption of 45 of the 47 noncounty borough forces followed application of the terms of the Police Act of 1946. Another trend toward integration is marked by the device of placing a single chief constable in command of two or more neighbouring forces. Examples are offered by the liberty of Peterborough and the city of Peterborough, by the county forces of Cumberland and Westmorland and by the borough of Hereford and Herefordshire. In some instances resort is had to such common commands where the forces concerned are rather small, and in any case they represent a kind of tentative or intermediate stage before outright consolidation.

Authorized strength of the metropolitan police in 1948 was 19,740, with the separately protected City of London adding 976 to the area's quota. In addition there were 55 county constabularies and 73 city or borough forces in England and Wales. These were responsible for policing almost 500 cities, boroughs and counties. The authorized strength of the county forces totalled 27,762 and that of the city and borough forces 20,950. Thus, the grand total for England and Wales was 69,428 officers and men

The Scottish establishment consisted of 27 county constabularies with a total authorized strength of 2,750 and 13 borough forces aggregating 4,573 men.

Ratios of police to population are highest in England, where in 1947 there were 1.57 police per thousand of population as against Scotland's 1.42 and 1.08 in Wales. Some of this disparity is caused by the varying ratios of urban and rural population, some of it by special influences affecting the gravity of the local police problem.

Although the British police system is deeply imbedded in local political institutions, the national government nevertheless maintains a certain degree of surveillance over the administration of even the smallest borough forces and county constabularies and extends financial and technical aid in various important ways. This represents an effort to introduce some degree of unity and coherence into a system that in most respects is wholly decentralized. Hence, the home secretary (for England and Wales) and the secretary of state for Scotland may enforce standards of efficiency in all police establishments. They also control the conditions of police employment (appointment, promotion, discipline, compensation, etc.) through widely ranging regulations. Such controls are made effective by the grant-in-aid annually made to each police establishment, totalling one-half of the net cost of each force, including pensions. With the various forces thereby made dependent in large degree upon the national exchequer, it is provided that the grants shall be made only to those meeting the required standards. Annual visitations by his majesty's inspectors of constabulary (four for the home office, one for the Scottish office) operate to enforce compliance.

The national government provides various central facilities. It operates seven forensic science laboratories, district recruiting offices, regional networks for wireless communication and ten training centres serving a number of neighbouring forces. It also bears a special relationship to the metropolitan police that springs from the unique position and character of that force. For example, the metropolitan police force is charged with certain imperial and national duties not readily performed by any other existing body. It is responsible for the protection of the royal family and the ministers of government, the regulation of traffic and maintenance of order in the vicinity of the houses of parliament, the guarding of government buildings and special precautions taken at state functions. All such would impose an inequitable burden upon the ratepayer of the metropolitan police district were it not for the special contribution of £100,000 a year that is made from the exchequer for the general support and furtherance of these purposes. The chief agency engaged in these duties is the special branch of the metropolitan police.

The metropolitan police force performs a widely heralded and generally misunderstood function in investigating certain crimes committed outside the metropolitan area. For the most part these excursions are confined to cases of murder; and since they are authorized only upon the request of the local authorities directly concerned, their number in any one year is small. The metropolitan police force also operates the Criminal Record office, a national registry of crimes and criminals, and publishes the daily *Police Gazette* which is distributed without charge to the police of Great Britain and Ireland as well as to certain parts of the empire and a few foreign forces. This publication carries details of persons wanted for crime, or who are already in custody and may be wanted by other jurisdictions, plus descriptions of property stolen and recovered.

POLICE COURTS, courts of summary jurisdiction held in London and certain large towns in England and Wales by specially appointed and salaried magistrates.

Police magistrates are appointed by the Crown. They must have been practising barristers for seven years or stipendiary magistrates for some place in England or Wales. One police magistrate has the same powers as two justices.

The precedent of appointing salaried magistrates was adopted in certain provincial towns under particular acts, and in 1863 the Stipendiary Magistrates Act enabled towns and boroughs of 25,000 inhabitants and upwards to obtain a stipendiary magistrate. There are at the present time (excluding metropolitan magistrates' courts) 18 stipendiary magistrates' courts throughout England and Wales.

In the United States there are no so-called police courts in the Federal system of courts except in the District of Columbia, where the President appoints, subject to confirmation by the Senate, two judges of the police court. In the various States, police courts, the presiding official of which is either a judge or a magistrate, have been created for many cities. They are elected by the voters, and try the violators of municipal ordinances.

POLICE POWER, in American constitutional law, the reserved or inherent powers of the States to legislate for the health, safety and morals of the community. The requirements of the 14th amendment of the U.S. Constitution that no State shall deprive any person of life, liberty or property without due process of law and the interpretation of that amendment by the Supreme Court to give it a supervisory jurisdiction over all State legislation restricting the exercise of individual rights, brought to the forefront the concept of police power as a basis for sustaining the exercise of novel State legislation. The ultimate test of constitutionality under the due-process clause being the arbitrariness to the judicial mind of the State legislation, the relationship between the legislation and the admitted power of State governments to act for the protection of the community in ways reasonably adapted to secure those ends becomes of acute and decisive importance.

Resolving this relationship in terms of traditional concepts of constitutional law, legislation provided that it falls within the police power of the States even though it interferes with property or personal rights does not then run afoul of the due-process clause of the 14th amendment. The ultimate question, of course, remains, namely the extent of the police power viewed in the light of the object sought to be effected by the legislation and the means devised to secure that object. The extent of the police power remains as the least defined of State powers. With a political collectivistic philosophy gradually supplanting the individualistic philosophy of an earlier age, illustrated by the increasing regulatory activities of government, the content of police power becomes an ever-broadening one. Supreme Court decisions reflect this change in later cases that overruled earlier decisions declaring unconstitutional State legislation seeking to protect interests not then deemed within the legitimate scope of governmental regulation.

The extent of the police power is generally said to embrace the protection of the health, safety and morals of the community. Regulation of the practice of trades directly related to the health of the community, restrictions upon the use of property for sanitation purposes, prohibition of immoral amusements, requiring the installation of equipment designed to protect the safety of employees or the public, the regulation of traffic, the regulation of hours of labour, are all types of governmental activity within the recognized domain of State legislation. The police power, however, extends to purposes not so clearly related to the health, safety or morals of the community. The conservation of natural resources, zoning legislation, the protection of the public against fraud and waste, the enforced destruction of property adapted for illegal uses but capable of permitted uses, are examples of the uncharted scope of the police power. It is commonly said that the police power may not be exercised purely for aesthetic purposes, but as a better understanding of the organization of society may illustrate an intimate relationship between the promotion of aesthetic ends and general social welfare, the concept of police power may well be enlarged to include purely aesthetic considerations. The Federal Government is said to possess no general police power. Inasmuch as the Federal Government is one of limited

powers and no general power for the protection of the health, safety and morals of the nation is granted to it under the Constitution, such a statement is accurate. But the Federal Government in the exercise of its granted powers may and does act for the promotion of ends within the concept of police power, and in this sense it has full freedom to protect the health, safety and morals of the community.

There are certain important differences between the exercise of the police power and other inherent State powers. The power of eminent domain, constitutionally restricted to employment for a "public use," can only take property by the payment of just compensation. The exercise of the police power may involve an equal "taking" of property but carries no obligation to compensate for such a taking. Again under the U.S. Constitution no State may pass legislation impairing the obligation of contracts already entered into. State action under the police power may, however, impair the obligation of contracts without conflicting with the constitutional prohibition, thus "taking" contract as well as property rights without compensation (See CONSTITUTION AND CONSTITUTIONAL LAW).

See Freund, *Police Power* (1904); Burdick, *Law of the American Constitution* (1922); Mott, *Due Process of Law* (1926).

POLIGNAC, an ancient French family, which had its seat in the Cevennes near Puy-en-Velay (Haute Loire). It can be traced to the 9th century, but in 1421 the male line became extinct. The herress married Guillaume, sire de Chalançon (not to be confused with the barons of Chalançon in Vivarais), who assumed the name and arms of Polignac.

The first historically important member was Cardinal MEXICOR DE POLIGNAC (1661-1742), a younger son of Armand XVII, marquis de Polignac, who became a distinguished diplomatist. In 1695 he was sent as ambassador to Poland, where he brought about the election of the prince of Conti as successor to John Sobieski (1697). In 1712 he was sent as the plenipotentiary of Louis XIV to the Congress of Utrecht. During the regency he became involved in the Cellamare plot, and was sent to Flanders for three years. From 1725 to 1732 he acted for France at the Vatican. In 1726 he received the archbishopric of Auch, and he died at Paris in 1742.

Prince JULES DE POLIGNAC (1780-1847), son of Count Jules (d. 1817), played a conspicuous part in the clerical and ultra-royalist reaction after the Revolution. Under the empire he was implicated in the conspiracy of Cadoudal and Pichegru (1804), and was imprisoned till 1813. After the restoration of the Bourbons he held various offices, received from the pope his title of "prince" in 1820, and in 1823 was made ambassador to the English court. On Aug. 8, 1829, he was called by Charles X. to the ministry of foreign affairs, and in November became president of the council. His appointment was taken as symbolical of the king's intention to overthrow the constitution, and, with the other ministers, he was held responsible for the policy which culminated in the issue of the Four Ordinances which were the immediate cause of the revolution of July 1830. On the outbreak of this he fled for his life, but was arrested at Granville and condemned to perpetual imprisonment. The sentence was commuted to one of exile by the amnesty of 1836. During his captivity he wrote *Considérations politiques* (1832). He spent some years in England, but was permitted to re-enter France on condition that he did not live in Paris. He died at St. Germain on March 29, 1847.

POLIGNY, a town of eastern France, in the department of Jura, 18 m N.N.E. of Lons-le-Saunier on the P.L.M. railway. Pop. (1936) 3,417. Under the name of *Polemiciacum* the town seems to have existed at the time of the Roman occupation. It lies in the valley of the Glantine at the base of a hill crowned by the ruins of the old castle of Grmont, once the repository of the archives of the county of Burgundy. The church of Montvillard dates from the 12th century and has a fine Romanesque tower. The church of St. Hippolyte, early 15th century, and a convent-church serving as corn market are of some interest. Poligny has a national school of dairy instruction.

POLISH LANGUAGE. Together with Polabian—a now extinct language spoken by the Slavs of the Elbe before they became Germanized—Sorb or Wendish, and Czechoslovak, Polish belongs to the western branch of the Slavonic languages. The nearest relative of Polish is Polabian, with which it forms the Lech group, but in view of the fragmentary character of the remains of that language (a few words and sentences inexactly recorded), it is difficult to state with any detail more than the purely phonological agreements. Those which are shared by the Lech languages and Sorb are: extreme palatalization of consonants before front vowels, the absence of the vowels *r* and *l*, a particular development of *or* and *ol* between consonants, and the tendency to lose the old distinctions of quantity. In all these points there is a contrast with Czechoslovak which to some extent bridges the gap between the western and the southern branches; but the characteristic features of West Slavonic are naturally common to Polish and Czechoslovak. The features which are generally considered as belonging to common West Slavonic are the development of *tj* and *dj* to *c* and *dz* (Polish and Slovak still have *dz*, but in Czech the sound has become *z*); the palatalization of consonants before *i*, *e*, *g* and *i* (only partially carried out in Czech, but Slovak agrees more completely with Polish); passage of *l* before back vowels and consonants to a sound like that in English "wall" (preserved also in Slovak dialects and in Old Czech, but the German *l* prevails in the modern language); loss of *x* between vowels, with compensatory development of a long vowel, shortening of long vowels which originally had a falling intonation; and the tendency to throw the stress away from the final syllable.

Polish is softer than Czech to the ear, owing to the predilection for palatal and sibilant sounds. The sentence melody, in spite of a regular accent on the penultimate, is in no way disagreeable, and the consonantal groups, which at first seem frightening, are easily pronounced after some practice. The survival of the old nasal vowels imparts to Polish an acoustic effect not unlike that of French.

The Slavonic inflexional type has been well preserved there are seven cases in both singular and plural (the dual has almost disappeared). The verb is of the normal type, except that it has lost the imperfect and aorist. A peculiar feature in the syntax of Polish is the impersonal passive construction, where the logical subject is put in the accusative after the neuter of the participle. The vocabulary of Polish has been considerably influenced by earlier Czech and also by German and Latin, but in the main the Slavonic character has not been seriously affected, and the number of words from other languages is negligible.

Polish dialects are usually divided into two broad divisions. The group to which the literary language belongs has preserved the old pronunciation of *sz* and *ż* (as in English "ship" and "azure" respectively), while the others have altered them to *s* and *z*. Scholars are disagreed on the question of Kašub, which is spoken by fewer than a quarter of a million people in the neighbourhood of Danzig. In its modern form, it is very close to Polish, especially from the point of view of vocabulary, but it has several features which make it possible that at an earlier stage it was more closely connected with Polabian.

BIBLIOGRAPHY.—The historical grammar of Bendl, *Łoś Nitsch, Rozwadowski* and *Ułaszyn* (*Gramatyka języka polskiego*—Cracow, 1923) is authoritative. It is slightly smaller than and covers a somewhat different field from the *Polish Language and its History* (in Polish), which is part III. of the *Encyklopedia Polska* (1915). Another excellent historical grammar is that by J. *Łoś*, *Gramatyka polska*. The grammar by St. *Szober* (Lwów—Warsaw, 1923) is the best descriptive work. The *Grammaire de la langue polonaise*, by A. *Mellet* and *Mme de Willman-Grabowska* (Paris, 1921) is the best sketch in a western language. The most complete dictionary is that of S. B. *Linde* (*Słownik języka polskiego*, Lwów, 1854-60), in 6 volumes. The *Handwörterbuch der deutschen und polnischen Sprache* in 4 vols., by *Konarsky*, *Islander*, *Goldschneider* and *Zipper* (1st edition, 1904), is good but bulky. The *Dictionnaire complet français-polonais et polonais-français* by W. *Janusz* (Lwów, 1908) is excellent, and better than A. B. *Chodźko's* *Dobry słownik polsko-angielski* (Berlin, 1912). A *Polish Phonetic Reader* by *Arndt-Chonicki* (London, 1924) supplements the larger works of Bendl and other Polish phoneticians.

(N B J)

POLISH LITERATURE. The Polish language belongs to the western branch of the Slavonic tongues, and exhibits the closest affinities with Czech, Slovak and Lusitan Wendish.

The earliest connected specimens of Polish prose are the fragmentary *Holy Cross Sermons*, and the complete *Psalter of St Florian*, both preserved in 15th century mss which are probably copies of earlier originals. The beginnings of poetry are represented by the *Bogurodzica* song, a hymn in honour of the Virgin, often sung by the Poles of the middle ages when going into battle. Legend ascribed the origin of the song to St Adalbert (Wojciech), in the 10th century. The oldest ms of the song is dated 1408.

The 15th century brings a fuller development of religious poetry. A number of devotional songs are preserved, being mostly translations of Latin or Czech hymns. Many of these songs are the work of Ladislaus of Gelnów, a Bernardine preacher, and of other friars of the same order.

The secular lyrics of the 15th century which have come down to us are not numerous but varied in contents, some being didactic in vein, such as the verses on table manners, some amatory and some in the nature of historical ballads on important public events, the victory over the German Knights in 1410, the defeat of Poles and Hungarians at the hand of the Turks in the battle of Varna (1444), Tartar invasions and other disasters, a list of the Cracow citizens who kill an unpopular nobleman (1461)—such are the facts commemorated. The coming controversies of the Reformation period cast their shadows before them in a vivid poem by Andrew Galka, on the doctrines of Wycif, which had become known through the Hussite movement in Bohemia.

Prose works in the 15th century are scarce. Polish 15th century prose is largely devotional: its longest specimen is a translation of the *Bible made for Sophia, queen of Poland*, about 1455; several books of the Old Testament only are preserved.

Latin Literature in Mediaeval Poland.—If literature in Polish is scanty, Latin literature in Poland throughout the middle ages is fairly abundant, especially in the field of history. The first chronicle of Poland written in Latin is an early 12th century work by an anonymous foreign monk, whom tradition called "Gallus." It tells the story of Poland from the beginnings of the Polish State in the middle of the 10th century till 1113. A hundred years later, a continuation of this chronicle was undertaken by Vincent Kadłubek, bishop of Cracow.

In the 13th and 14th centuries, the number of chronicles increases. We may single out that of Jan of Czarnków (d. 1389), which gives a vivid account of conditions in later 14th century Poland. A great centre of intellectual and literary activities was created by the foundation of the University of Cracow. The university was originally erected as a legal college in 1364, in 1400 it was reorganised on a broader basis, mainly through the efforts of Queen Jadwiga, who, by her marriage with Duke Jagiello, united Poland and Lithuania in a powerful monarchy. It is in the shadow of Cracow university that Poland's most distinguished mediaeval historian, Johannes Długosz or Longinus (1415-1480) undertakes his great Latin work on the history of the country. Through diligent study of the royal and ecclesiastical archives, which were open to him, and of the works of native and foreign historians, Długosz produced in his *Historia Poloniae* the first monumental work of Polish historiography which unites critical scholarship with literary excellence. History is supplemented by the lives of saints, ever popular in the middle ages.

Latin poetry in mediaeval Poland, as in other European countries, is represented by church hymns as well as by the Latin carollings of the *clerics vagantes*. As the Renaissance approaches, the ground for the elegant Latin versification of the humanist scholars is prepared.

Early Polish Printed Books.—A printing-press was in existence at Cracow about 1474. But it was only about 1500 that a permanent printing office was established at Cracow by Jan Haller, followed by a number of others. Among the books they printed, Latin are still in the majority, but Polish books began to appear in increasing numbers. A large part of them is devotional. Fiction, as elsewhere, is represented by "chap-books" on such subjects of international popularity as the fabulous histories of

Alexander the Great and the stories collected in cycles like the *Gesta Romanorum* or the *Seven Sages*. Among the translators who provided this sort of literary food, Bernard (Biernat) of Lublin (c. 1515), takes a prominent place, chiefly by his rhymed paraphrase of *Aesop's Fables* and the romantic *Life of Aesop*. Next to him stands Jan of Koszyczyk, who paraphrased the ancient fables associated with the names of King Solomon and his legendary opponent, the shrewd peasant Marculf. These humours of *Marchio*, as he is called in Polish, are a fine specimen of racy popular speech. So are some religious songs, especially Christmas carols, interlarded, in the fashion of the time, with jocular details from contemporary life. With such literature, still essentially mediaeval in character, we may rank even the elaborate and widely-read *Chronicle of the World* (1551), written in Polish by Martin Bielski, as well as his *Satires* and his allegorical play *Justinus and Constantia*, the first morality in Polish.

Humanism and the Reformation.—A period justly called "the golden age" of Polish literature was prepared by the spread of Renaissance humanist culture, and of the doctrines of the Reformation. Poland, like other countries, began to produce Latin prose and poetry during the 16th century. The witty and licentious, satirical and erotic epigrams of Bishop Andrew Krzycki (d. 1537), the serious political and moral epistles of the diplomat Joannes Dantiscus (a burgher of Danzig, d. 1548), the tender elegies of Clement Janicki (Janicki), dead in his prime in 1543, rank with the best Latin poetry of modern Europe. The mediaeval historical work of Długosz is surpassed in grace by the humanist Latin of Martin Kromer's *History of Poland* (1555). Poland's greatest political thinker of the period, Andrew Frycz-Modrzewski, used Latin for his work *De reipublica emendanda* (1551), a systematic treatise on social philosophy, and as late as the 17th century a Polish jesuit, Mathew Sarbiewski (d. 1640), became known throughout Europe as "the Christian Horace" for the beauty of his Latin religious lyrics. On their travels abroad, Polish students not only perfected their Latin and Greek, but witnessed the new growth of vernacular literatures based on classical models, and this awakened the ambition to rival foreign achievements by Polish verse and prose. Such ambitions were stimulated by a Protestantism which favoured the vernacular. After the council of Trent and the coming of the Jesuits (1564-1565), Protestantism began to decay, but what it had done for national literature remained effective. The Catholic Polish bible of Bishop J. Wujek (1599) has greatly influenced language and style.

The Poets of the Golden Age.—The year 1543 is a landmark, being the date of the appearance of the first important work of Nicholas Rej of Nagłowice (1505-1569). After a somewhat idle youth he wrote a long series of poetical works. He turned Calvinist in middle age, and produced a translation of the Psalms. His principal and most mature works—the *Image of an Honest Man's Life*, in verse, and the more elaborate prose *Life of an Honest Man*—present his moral ideas, being those of a good-natured country gentleman. The latter work is also known as *The Mirror*.

Rej's popularity was outshone by the fame of Jan Kochanowski (1530-1584). He resided in Paris, where he met Ronsard. Returning to Poland, he became in 1564 secretary to the king. His less important early works, among which a paraphrase of Vida's poem on the *Game of Chess* may be singled out, were followed by epigrams called *Trifles* ("Fraszki") and by numerous *Songs* varied in tone, idea and form like the Odes of his master Horace, yet instinct with modern sentiment. In a longer poem, *The Satyr*, he deals with the serious political problems of Poland in his time, in *St John's Eve* (Sobótka) he delights us with pictures of native and country life. Kochanowski's only dramatic work, *The Dismissal of the Grecian Envoys* (Odprowa poslow greckich) (Eng. tr. Noyes and Merrill, Berkeley, Cal., 1918), is a verse tragedy in the Greek style, with choruses, on a subject from *Iliad* III. Another work of Kochanowski's, his verse paraphrase of the *Psalms*, remains one of the masterpieces of religious lyrical poetry in Polish, only rivaled among his works by the *Trenny or Laments* for his little daughter Ursula who died in childhood (Eng. tr. Prall, Berkeley, Cal., 1920). Another great lyricist of the period, Nicholas Sep Szarzyński (1550-1581) died

in his prime. He introduced the sonnet into Polish poetry. The long descriptive and satirical poems, in Polish and Latin, by the townsman Sebastian Klownicz (1545-1602) are interesting as illustrations of the social life of Poland. Simon Szymonowicz (or Simonides, 1554-1642), a burgher of Lwów, and an elegant Latin poet and dramatist, acquired fame as a Polish writer by his Pastorals which imitate Theocritus and Virgil, but contain vivid scenes from Polish life.

Prose Classics of the 16th Century.—Simultaneously with poetry, Polish prose rises into excellence. The religious and political controversies of the hot-blooded prelate Stanislas Orzechowski (1515-1566) were conducted in a style of admirable vigour. The version of Castiglione's *Il Cortegiano*, by Lucas Górnicki (1566) is a fine monument of Polish prose. Ecclesiastical eloquence found its master in the Jesuit Peter Skarga (1536-1612), indefatigable as the protagonist of the Catholic cause in Poland. His *Lives of Saints* have remained a religious classic; but his *Parliamentary Sermons* published in 1597 are the crown of his life's work. It is here that Skarga, exposing the faults of the Polish national character and foretelling the downfall of the State, challenges comparison with the Hebrew prophets.

FROM BAROQUE TO CLASSICISM

The Age of Baroque.—The 17th century, although a period of wars and invasions, is rich in literary production. Italian models, with all the extravagance of the *seicento* manner, give to 17th century Polish literature, variety and colour, but at the expense of unity and moral elevation. Important works, censored by the clergy, have come to light only in recent times.

Poets of the 17th Century.—The military events of the period, together with the influence of Tasso's epic (translated into Polish, as was also Ariosto's, by Peter Kochanowski) inspired a number of epic poems dealing with contemporary history. The principal poet of the period, Wacław Potocki (1625-96) composed an enormous epic on the Chocim campaign of 1621 against the Turks and followed it up with *The New Mercury* and *The Turks' Defeat at Chocim* on the victories of John Sobieski. He also left behind in his two large collections of minor verse, *The Garden* and *Morale*, and both illustrative of all aspects of the Polish life of his time. Potocki is also the author of a huge body of religious verse, and of several verse romances both original and translated. Potocki was preceded by Samuel Twardowski (1600-60) author of three interminable rhymed chronicles on the stormy events of the time. A fantastic verse story of his, *The Beautiful Pasqualina*, is noteworthy as a paraphrase from Montemayor. A bitter satirist appeared in Christopher Opaliński (1610-56). His brother Lucas (1612-62) is also a satirist, and a better poet, as well as a political writer of merit. He wrote also an *Art of Poetry*. Vespasian Kochowski (1633-1700), in importance next to Potocki, surpasses him in artistic refinement. Having fought in many Polish wars, he told the story of some of them in voluminous epics. But neither these nor his long religious poems are as important as his *Polish Psalms*, modelled on Kochanowski's verse Psalter, but written in poetic prose and embodying much of the poet's own inner life. A poet of peculiar charm and grace meets us in the person of Andrew Morsztyn (1613-93), who translated Tasso's *Aminta*, Corneille's *Cid*, and Marini's *Psyche*, and represents, in his own lyrics, the first instance of the deep influences of Italian and French literature. Simon Zimorowicz (1608-29), a burgher of Lwów, who died young, shines like a meteor by the freshness and poetic sentiment of his love lyrics *Rozminki*. His elder brother Joseph Bartholomew (1597-1677), gives us delightful glimpses both of town and country life, and interesting accounts of quiet as well as of stormy times, in his *Idylls*.

18th Century Prose.—Among prose writers, we may single out: the Dominican preacher Fabian Birkowski (1566-1636), a baroque successor to Skarga; the learned and voluminous Latin and Polish writer Simon Starowolski (1585-1656), whose Latin works include the first history of Polish literature; Count Andrew Maximilian Fredro (1620-1697), whose *Proverbs* are a collection of maxims and observations comparable with the works of the French moralists of the time; Stanislas Hieracius Lubomirski

(c. 1640-1702) who wrote several comedies based on Italian and Spanish originals, and finally, John Chrysostom Pasek (1630-1701), the king of Polish diarists, whose adventures in war and peace are embellished beyond the truth, yet simply and spontaneously narrated.

The Saxon Period.—The era of baroque was prolonged into the sad period of political decay and intellectual stagnation covered by the reigns of Augustus II and III (1697-1763). Specimens of literature worth recording, like the unpretending verse of Poland's first poetess Elizabeth Druzbicka (1695-1765), are isolated in this age. But even this darkest period of Polish civilisation is illuminated by such efforts as Stanislas Konarski's (1700-1773) reform of the secondary schools conducted by the Piarist fathers and his proposals for a thorough reform of Polish literary style (*De emendandis eloquentiae viis*, 1744).

The Era of Enlightenment: Poets.—The reign of the last king of Poland, Stanislas Augustus Poniatowski (1764-1795), is a period of literary development. Both the general atmosphere of the age of rationalism, and the peculiar conditions of Poland—the imminent danger of ruin to the commonwealth—gave the literature of the period a predominantly didactic character, satire, as elsewhere in Europe, is prominent. Thus, the representative writer of the age, Ignatius Krasicki (1735-1801) was, above all, a satirical poet. Krasicki is a typical eighteenth century prelate of the sort not uncommon in western Europe at the time. After his early heroic-comic poem, *Myszeis*, on the battle of the rats and mice against the cats, he soon rose to a higher level in his epic satire on monastic life, *Monochomachia*. This was followed by a biographical novel, *The Adventures of Doświadczyński*, which contains a good deal of satire on the Polish gentry. A second novel, *Pan Podstoli*, is more didactic in design. It draws Krasicki's picture of the ideal country gentleman. The high-water mark of Krasicki's work is reached in his *Satires*, the supreme achievement of 18th century classicism in Poland. They are followed by *Epistles*, but his most popular work is his *Fables*, which has made him the La Fontaine of Poland. His voluminous prose works include the first Polish survey of universal literature.

The poet next to him in the favour of his contemporaries, Stanislas Trembecki (1755-1812) is Krasicki's equal in clearness and expressiveness of language, but otherwise inferior to him. Trembecki excels in his *Fables* and *Epistles* by perfection of phrase and melody of verse. The fiery satirist Kajetan Wegierski (1755-84), who died in his prime after a youth of dissipation, was perhaps more deeply influenced than others by the French writers of the age, whom he loved to translate. The later poets of the period mark the transition from rationalism to romantic sentiment and include Francis Karpiński (1741-1825), and Francis Kniazinin (1750-1807).

Prose Writers of the 18th Century.—Bishop Adam Naruszewicz (1733-96), owes his chief title to fame to his ponderous history of mediaeval Poland, the first scholarly treatment of the subject. Stanislas Staszyc (1755-1826), a liberal-minded priest, began his career with powerful pamphlets advocating political and social reform, and continued it after the partitions of Poland as a scientist and an organiser of research and industry. His fellow-reformer, Father Hugo Kollontaj (1750-1812), surpassed him as a political journalist and in his later work, as a philosopher.

The Theatre.—It was for school theatres that Francis Bohomolec wrote his comedies (1755-60), based on French models, chiefly Molière. At the same time, Wacław Rzewuski (1706-1779), wrote tragedies from Polish history in the French classical style for the private theatre at his residence. But it was only with the foundation of the first public theatre in Warsaw in 1765 that Polish dramatic literature got a permanent footing; and the manager of that theatre, Wojciech Bogusławski, himself a popular playwright, is the real creator of Poland's theatrical tradition. It was for this theatre that Francis Złobicki (1754-1811) wrote his satirical comedies, drawing for subject-matter on obscure French sources, but presenting Polish figures and Polish ways. *The Dandy's Courtship* (*Frzyk w zalotach*) is his masterpiece. The famous comedy *The Return of the Deputy* (*Powrót Posła*) by Julian Ursyn Niemcewicz (1757-1841), was written to help the

cause of political reform Niemcewicz himself, auto-de-camp to Kościuszko, made his mark in many fields of literature. His *Songs of Polish History* (Śpiewy historyczne) are still read and recited in schools. His *Fables and Satires*, comedies and tragedies belong to the 18th century, but by his translations of English ballads and romantic poems, as well as by his novels he heralds the coming of a new age. His *Memoirs* are a valuable chronicle of the transition period.

THE NINETEENTH CENTURY

The Romantic Era.—Soon after the disappearance of the old Polish State the vitality of the nation was manifested not only by military effort during the Napoleonic Wars, but also by intellectual and literary achievements. The University of Vilna (which had received its charter in 1579) entered on a flourishing period soon after 1800. The great poet Mickiewicz came from the ranks of its pupils. In the South-Eastern part of the borderlands, the Lyceum or public school of Krzemieniec in Volhynia displayed similar activities. In Warsaw itself a "Society of Friends of Learning" came into being in 1800, and a *Dictionary of the Polish Language* by Samuel Linde was among its many undertakings. Warsaw remained the capital of literary taste, and in the first decades of the century, the classicism of the former age still reigned there. It is represented by the poet and critic Kajetan Koźmian the author of Polish Georgics (*Ziemiastwo*), and bishop J. P. Woronicz (1757-1829) who, in his didactic poem *Sybulła*, drew comforting conclusions from a philosophical survey of Poland's history.

The strong didacticism of the classicist era also inspires the literary activities of Mme Clementina Hofman (née Tanska), who produced the standard works of Polish educational fiction.

At the very end of its period classicism still gives Poland one great writer in Count Alexander Fredro (1793-1876) the author of the best Polish comedies. A soldier under Napoleon, he saw the masterpieces of French classical comedy in Paris and followed Molière. His first piece, *Pan Gdliab*, a satire on *nouveaux riches*, was produced in 1821. He wrote about twenty other comedies, and then abandoned production for fifteen years. At his death, however, he left behind a number of further plays in ms. His best-known works are: *Zemsta* (The revenge), which satirizes the mania for litigation among country gentlemen, *Śluby panieńskie* (Girls' Vows), *Damy i huary* (Ladies and Hussars, Eng. trs. Noyes, 1925), *Mąż i żona* (Husband and Wife), *Dozywocia* (The Life Interest) and *Pan Jowalski* (The old Story Teller). The comedies, mostly in verse, portray the Polish country gentry to which Fredro belonged.

Midway between the classicists and the romantics stands the curious figure of Casimir Brodziński (1791-1835). His verse idyll *Wesław*, in which the manners of the peasants of the district of Cracow are portrayed, is classical in style and diction, but romantic in sentiment. His essay on *Classicism and Romanticism* and on *The Spirit of Polish Poetry* (1818) proclaimed the importance of national tradition and popular elements for literature, and in his lecture *On Polish Nationality* (1831) he partly anticipated the notion, fully developed by the great romantics, of Poland as a "chosen people." The boldness of new ideas was combined with supreme power of poetic achievement in Adam Mickiewicz (q.v.) (1798-1855), who soon became the acknowledged leader of the Romantic Movement.

Juliusz Słowacki (1809-49) is in many ways more representative of the essence of Romanticism than Mickiewicz. His genius develops under the influence of Byron. *Podróż na Wschód* (A Voyage to the East), is a poem in the manner of *Childe Harold*. Słowacki's fantastic verse play *Koridjan* combines reminiscences of a Warsaw conspiracy against the tsar in 1820 with the influence of *Manfred* and of *Hamlet*. Mickiewicz's *Księga Pielgrzymstwa* (Books of Pilgrimage), written in biblical prose for the comfort of Polish exiles in France, are paralleled by Słowacki's *Ahelli*, in which the Polish emigrant community in western Europe is represented under the allegorical disguise of a body of exiles in Siberia. It is, however, under the direct influence of Shakespeare that Słowacki attained his supreme poetic triumphs in drama.

His verse tragedies, *Balladyna* and *Lalla-Weneta* are placed in a legendary, pre-historic Poland. *Masepa* takes place at the court of a Polish noble of the 12th century. The Polish world of the 15th and 18th centuries is the scene of two further plays of Juliusz Słowacki, *Horsztyński* and *Złota Czapka* (The Golden Skull), both unfortunately incomplete. The influence of Victor Hugo gives a sensational tinge to *Beatrice Cenci*. From Shakespeare and Victor Hugo, Słowacki passes under the influence of Calderon he deals in Calderonian style with events from 18th century Polish history in his dramas *Ksiądz Marek* (Father Mark) and *Sen Srebrny Salomei* (The Silver Dream of Salomea). The last years of Słowacki's short life were spent among the Polish emigrants in Paris. The political and religious doctrines, the illusions, disillusionments and quarrels which agitated that little world, are mirrored in Słowacki's satirical epic *Bemowski*, which occupies, in his career, the place of *Don Juan* in Byron's. The mystical creed, which possessed the poet entirely in his latest years, inspired one of his most sublime works, the unfinished epic *Król Duch* (The Spirit King). The poet's complete spiritual philosophy of the mystical period is embodied in a prose treatise *Genesis i Duch* (The Genesis from the Spirit), which curiously anticipates, in some of its ideas, the theory of evolution.

Zygmunt Krasiński (1812-1859), long considered the equal of Mickiewicz and Słowacki, rose to an extraordinarily high level in his precocious early work. He became absorbed in meditations on the social revolution which after 1830 seemed to be threatening all Europe, and he put his vision of it, at the age of 21, into a drama *Nieboska Komedja* (The Un-Divine Comedy) (Eng. tr. Kennedy and Umńska, 1923). Krasiński's second work, the drama *Irzydon* (Eng. tr. Noyes, 1927), placed in Rome in the second century of our era, has for its subject an attempted revolt of the Greeks against the Roman Empire. The attitude of the Christians, who refuse to fight, is the cause of failure. Krasiński links up his subject with philosophical speculations on the historical mystery of Poland's sufferings. His creed in this matter is embodied in a visionary poem called *Przedświt* (The Dawn), in which he extols the passive heroism of his oppressed country as the earnest of victory in the ideal sphere. These ideas are repeated in several didactic lyrics called *Psalmi Przyszłości* (Psalms of the Future). Krasiński's waning talent spent itself on political, religious and philosophical pamphlets and lyrics.

All the three great Romantic poets had come, for a time under the spell of an emigrant thinker named Andrzej Towiański (1799-1878) who had woven religious and patriotic mysticism together into the creed of a new sect, making of Poland a "messiah among nations." Krasiński's thought, in particular, also shows close relation to that of August Cieszkowski (1814-1894), the most distinguished and independent of a group of Polish philosophers who were disciples of Hegel ("Our Father," selections in English by Dr. W. Rose, 1924).

It is only in the 20th century that another Polish metaphysician of the Romantic period, Joseph Maria Hoene-Wronski (1778-1853), who wrote mainly in French, has won an increasing amount of international recognition.

Among the lesser romantic poets, the so called "Ukrainian school" forms a group apart. Its earliest representative, Antoni Małczewski (1793-1826), preceded even Mickiewicz as the author of a Byronic tale in verse. His romance *Marya* (Mary, 1825), breathes all the charm of chivalrous tradition and melancholy steppe landscape associated with Poland's south-eastern border.

Byronic colours are laid on more thickly by Seweryn Goszczyński (1803-1876) in his verse tale *Zamek Kanowski* (Kanow Castle), full of the horrors of age-old class war between the Ukrainian peasantry and the Polish borderland gentry. In his later work, he became a forerunner of realism.

The third most prolific singer of Ukrainian traditions and landscape in Polish poetry, Joseph Bohdan Zaleski (1802-1886), is a lyrical poet of great melody, but fatal facility. In his most ambitious effort, the philosophical poem *The Spirit of the Steppe* (*Duch od stepu*) he endeavoured to reconcile the Romantic dreams. See the study by Monica M. Gardner: *The Anonymous Poet of Poland* (Cambridge, 1919).

of the high dignity of Poland's sufferings with a moral and Christian view of her past errors and contemporary fate

Another region of Poland's historical domains, the Masovian plains in the centre of the country with their purely Polish peasantry, are the subject of the lyric poetry of Teofil Lenartowicz (1822-1893) although he spent his later years as a sculptor in Florence, he never ceased to sing of Polish country life

His counterpart is Wincenty Pol (1807-1872), who sings with equal persistence of the old-world life of the country gentry. A soldier in the insurrection of 1831, he commemorates this in a series of stirring and popular songs (*Pieśni Janusza*). A Professor of geography in his later days, he produces a picturesque descriptive account of Poland in verse (*Pieśń o Ziemi Naszej*) and several geographical works in very vivid prose

What the Ukrainian group did for the South-East, and Lenartowicz and Pol for central Poland, was done for the North-Eastern domains of the historical Poland (Lithuania and White Ruthenia) by Ludwik Władysław Kondratowicz, known as Syrokomla (1823-1862). A son of the minor gentry of those lands, he is at his best when drawing on his memories of his own youthful surroundings (as in the two charming longer poems on the *Early Life and School-Days of Jan Deborg*)

The romantic inspiration still produced a poet of action in Mieczysław Romanowski (1834-1893), who died a hero's death in the ranks of the insurgents of 1863. He had shown promise in a longer narrative poem of Polish town life in past ages (*Dziwacz z Sacza*), but this bears clear traces of the influence of Mickiewicz's epic masterpiece. It is echoes also of the song of the great Romantic masters that we catch everywhere in the poetry of Kornel Ujejski (1823-1897). He had made his mark, at the age of twenty with the verse tale *Marathon*. Not long afterwards, the national disaster of the Galician peasant riots of 1846 inspired him to write a series of elegies entitled *The Lamentations of Jeremiasz* (Skarga Jeremiego), one of which, the *Choral Song* became the anthem of national woe. Before fading away utterly, the Romantic flame once more leaps up wildly in the enigmatic and convulsive, but intensely inspired poetry of Cyprian Norwid (d. 1885). The poet lived in disregard and neglect, and only came into his own long after his death through the efforts of a 20th century critic (Z. Przesmycki)

Of novelists of the romantic period, the very spirit of romance seems incarnate in Michael Czapkowski, who began active life as a Polish insurgent in 1831 and ended it as a Mussulman and a pasha in the Turkish Army. His novels, chiefly from the history of Poland's 18th century wars, are marred by wild improbabilities and artificial glitter. Higher literary value distinguishes the works of Count Henry Rzewuski (1791-1866), especially his stories from 18th century Polish life *The Memoirs of Severn Sophia and November* (*Listopad*)

We are on the road from romance to realism in the novel and plays of Joseph Korzeniowski (1797-1863). His drama *The Carpathian Mountaineers* (*Karpaccy Górale*) is aglow with the colours of folk-lore, his comedies, such as *The Jews* (*Zydzi*) or *Miss and Mrs* (*Panna meżatka*) take us out of the region of old-fashioned comic types into the sphere of modern individualism in character-drawing, and his novels, e.g., *The Schemer* (*Spekulant*) or *The Neighbourhood* (*Kolokacja*) are satiric

The transition from romance to realism is shown in Joseph Ignatius Kraszewski (1812-1887), whose untiring pen produced over 500 volumes of fiction, history, criticism and other literary matter. His historical novels have made him the Scott of Poland: but he deals with Polish contemporary life as well. 'The picture of the decay of the land-owning aristocracy in *Morturi* shows deep insight. Of his historical novels, those relating to the "Saxon period" of the early 18th century—such as *Brühl* or *Countess Kosel*—are the best. His influence on readers and other novelists has been enormous.

In the field of the historical novel, Kraszewski is almost equalled in popularity by Zygmunt Kaczkowski (1826-96), who excels in stories of the troubled partitions of Poland. Another popular novelist is Theodor Tomasz Jez (whose real name was Zygmunt Miłkowski, 1824-1915), an insurrectionary soldier and an exile,

who has described the history and folk-lore of the Balkans.

Of historians and essayists, Joachim Lelewel (1786-1861), laid the foundation of modern Polish historical research. Among his followers Karol Szańoch (1818-68), is conspicuous for the literary qualities of his work, as shown chiefly in his monographs of *Jadwiga* and *Jagiello* and of *Two Years of Polish History* (viz., 1647-48). History and literary criticism are combined in the brilliant writings of Maurycy Mochacki, who became the historian of the insurrection of 1830. In Julian Klaczko, Poland produced a distinguished student of Dante and of renaissance art: but his writings were mainly in French.

The Period of Realism.—The disaster of the second Polish insurrection, in 1863, produced violent reaction against all Romantic dreams both in politics and in literature. The mood of realism was fostered from abroad by the progress of natural science, of economic development, and of political liberalism in Western Europe. The few eminent poets of this age of prose make themselves the heralds of its ideals. The representative lyricist of the positivist generation, Adam Asnyk (1830-97) passed in his own career from the romantic exaltation of national martyrdom to the advocacy of positive social work for popular education: he even became the founder of the "People's School Society" (1891). His mature lyrics are lyrics of thought rather than feeling, and even in his nature poetry reflection predominates over enthusiasm. Feeling abounds in the verses of his most distinguished contemporary in Polish poetry, the poetess Marie Konopnicka (1840-1916) both in her lyrics and her short stories, the dominant note is one of profound pity for the poor. In her long epic, *Mr. Balcer in Brasil* (*Pan Balcer w Brazylii*), she tells the story of the sufferings of Polish peasant emigrants in the Brazilian forest.

The outstanding modern journalist, Aleksander Świętochowski (1849-1938) waged fearless war, both in his articles and his dramas, for the liberal ideals. His younger contemporary, Andrew Niemcewicz (1804-1921) was chiefly preoccupied, in his journalism and his poetry, with the new industrial problem.

In the sphere of the novel, Madame Eliza Orzeszko (1842-1910), represents peasants, Jews, great industrialists, but she always returns to the life of the Polish country gentry in her native Lithuania. Bolesław Prus (real name Aleksander Głowacki, 1847-1912) is, like Dickens, whom he resembles by his humour, a child of the city: the scene of his best social novels, like *The Puppet* (*Lalka*) and *The Emancipated Woman* (*Emancypantki*), is laid in his beloved Warsaw. But he also gave a touching account of the peasant's attachment to the soil in *The Outpost* (*Placówka*). In his largest work, *The Pharaoh*, he performed a *tour de force* by expressing modern ideas in a story of ancient Egypt. Poland's greatest modern writer is Henryk Sienkiewicz (q.v.) (1846-1916), whose *Quo Vadis* became known to all the civilised world, while his epic novels from Polish history—*The Trilogy* and *The Knights of the Cross*—together with the great historical paintings of Jan Matejko revived the romantic sense.

Younger novelists have imitated the extremes of the *roman naturaliste* in the fashion of Zola. Adolf Dygasński (d. 1903) tells depressing stories of peasant poverty in Russian Poland: but he achieved his highest successes in his accounts of animal life in the Polish country-side, chiefly in *The Feast of Life* (*Gody Zycia*). The high-water mark of *naturalisme* in Poland is reached in the numerous plays and novels of Mme Gabrielle Zapolska (d. 1923), an actress.

The historical verse play was cultivated with some effect by the illustrious Cracow scholar J. Szujski (1835-83), who, however, is notable chiefly as the author of a monumental *History of Poland*. He became one of the founders of the so-called "Cracow School" of moralising historians, represented beside him with distinction by Walerjan Kalinka (1826-86). Among later members of this group, the historian and jurist Michael Bobrzyński (1849-1935) must be mentioned. While the Cracow school chiefly stressed the faults which contributed to Poland's ruin, Warsaw historians like Tadeusz Korzon (d. 1917) and Władysław Smoleński (d. 1925) consciously emphasized the positive achievements of the nation. The stormy history of Poland

in the 18th century found an able exponent in Ludwik Kubala (d. 1918), whose vivid pages inspired Sienkiewicz. More recently, the history of Poland's struggles for independence during the 19th century has been treated with brilliant talent in the writings of Professor Simon Askenazy. In recent decades, Count Stanislas Tarnowski, president of the Polish Academy (d. 1917), Professor Peter Chmielowski in Warsaw (d. 1905) and Professor Aleksander Bruckner in Berlin (1856-1939) won distinction.

POLISH WRITERS OF RECENT TIMES

The "Young Poland" Group.—During the last decade of the 19th century a whole group of young exuberant talents appeared together in the forefront of Poland's literary life. Dissatisfied with the utilitarian character of the art and poetry of the preceding period, they organised themselves into an independent body, soon known as "The Young Poland," with the view of working out a new theory of art, based on absolute individual freedom in form and matter. True to this principle, practically every one of them tried his best to find his own way of expression. The first among these young poets to gain fame was Kazimierz Tetmajer (1865-1904), whose love lyrics are comparable to the best work of the French Parnassians. The modern poetry of France and Belgium found a gifted and congenial interpreter in the person of Zenon Przesmycki, who wrote under the name of "Miram" (b. 1861). The most forceful individuality of this group was Stanislas Przybyszewski (1868-1927), who, having spent several years among the young Scandinavian and German writers, came back to Poland in 1893 to become at once the leader of the group and the editor of their organ, a weekly called *Zycie* (Life). His dramas full of fatalistic terror, and his prose poems, dealing with the mysteries of love and death, became the fashion of the day.

The art editor of the new weekly was Stanislas Wyspianski (1869-1907), a painter of great originality, who became also the foremost Polish dramatic poet of his age. His leading idea was to unite in the theatre the arts of painting, of architecture, and of poetic drama. Gradually his attention turned to national subjects, and especially to the problem of national strength and weakness, which is the root of the three dramas, *Warszawianka* (The Song of Warsaw), *Lelelewel*, and *Noc listopadowa* (The November Night). *The Legion*, a play of which the tragedy of Mickiewicz as the leader of Polish romanticism is the subject-matter—links the past with the present. In three powerful dramas—*Wesele* (The Wedding, 1901), *Wyzwolenie* (Deliverance), and *Akropolis*, he deals with Poland's deliverance.

Jas Kasprowicz (1860-1926) was no doubt the greatest Polish lyrical poet of his day. With him, as with Thomas Hardy, the problem of evil and human suffering is the predominant subject. This problem finds expression in *Chrystus* (Christ), *Na Wzgórzu Śmierci* (On the Hill of Death), and finally in the cycle of hymns *Ginącemu Światu* (To the Perishing World). In his later years, the poet attains the wisdom of a resigned sage, which speaks from every line of his last volumes called *Księga Ubogich* (The Book of the Poor) and *Mój Świat* (My World).

The mood of spiritual calm is also the dominant note of Leopold Staff (b. 1878), who started his poetical career with *Sny o Potęgę* (Dreams of Might): but struggles with the eternal mysteries are not absent even from his later volumes, e.g. *Ułamek* (The Eye of the Needle, 1927).

Novelists.—Brought up under Russian oppression, Stefan Żeromski (1867-1925) indulges in pessimism. The most typical of his novels are "*Ludzie Bezdomni*" (The Homeless), *Popioły* (Ashes), dealing with the Napoleonic period, and the story-cycle *Wiatr Od Morza* (The Wind from the Sea)—with his final work, *Przedwiośnie* (Before Springtime) in which he gives a threatening picture of the new Poland.

The winner of the Nobel Prize for literature in 1924, Władysław Stanislas Reymont (1868-1925) was a born realist. His early ambition was to draw a picture of life in a big industrial city. After a stay at Łódź, he produced a novel called *Ziemia Obiecana* (The Promised Land, Eng. tr. M. H. Dziewicki, 1927) which caused him to be hailed by critics as "The Polish Zola." Like Zola, but on a larger scale, he afterwards wrote a novel of

peasant life as the result of five years of incessant work there appeared his tetralogy "*Chłope*" (The Peasants, Eng. tr. by M. H. Dziewicki, 1924). This great epic novel gives a rich and vivid picture of Polish peasant life especially in the Tatras mountains.

The most talented representative of exoticism in Polish literature is Wacław Sieroszewski (1858-1945) whose stay in political exile among the native tribes of northeastern Siberia resulted in a series of fascinating short stories. An artist of rare subtlety and literary skill was Wacław Berent (1873-1940). His novels *Próchno* (Rot) and *Osmiema* (The Winter Cure) contain a penetrating analysis of the late 19th century mood. His later work, *Żywe Kamienie* (Living Stones) is a rich and interesting picture of mediaeval life. Among disciples of Sienkiewicz, the most talented is Józef Weyssenhoff (1860-1932), whose hunting stories *Soból i Panna* (The Sable and the Girl, Eng. tr. Mme K. Zulkarszewska, 1928) describe Poland's Eastern borderland.

Literature in Poland After the World War.—With the reunion of Poland, her literature must lose influence as a national force. But even during the War, there came into being two notable groups of young poets, one in Poznań (the capital of the western provinces of Poland), another in Warsaw. The latter soon surpassed the former, and became the centre of a boldly aggressive and joyous view of life. Among these young poets the most promising are J. Tuwim, K. Wierzyński, J. Lechoń, A. Słonimski, and J. Iwaszkiewicz.

Another group, headed by E. Żegadłowicz and calling itself *Czwartak*, looks for inspiration to the quietness and retirement of country life, and to the simple pieties and legendary traditions of the folk. In Miss I. K. Iłakowicz the new Poland possesses a poetess of great lyrical charm. The terrible experiences of the war, and of Bolshevism on the Eastern border, found expression in some notable works by such writers as Mme Z. Kossak-Szczucka (*Posoga*—The Blaze—Eng. tr. 1926). The wanderings of Polish exiles in war-time over the vast territories of European and Asiatic Russia have born literary fruit in the vigorous and racy stories of F. Goetel, as well as in the spirited yarns of wild adventures in Mongolia by O. Ossendowski. Otherwise, the novels written since the War, like the *comedies and dramas*—the works of W. Perzyński and others—deal with daily reality. The tradition of *poetic drama*, in the fashion of Słowacki and Wyspiński, is kept up by the verse plays of K. H. Rostworowski, E. Żegadłowicz and L. H. Morstin. The reflective post war mood is shown most ably in the novelist Juliusz Kaden Bandrowski.

(R. Dv.)

POLISH SUCCESSION WAR (1733-1735), the name given to a war which arose out of the competition for the throne of Poland between the elector August of Saxony, son of August II (the Strong), and Stanislas Leszczyński, the king of Poland installed 30 years before by Charles XII of Sweden and displaced by August the Strong when Charles's projects collapsed. The claims of Stanislas were supported by France, Spain and Sardinia, those of the Saxon prince by Russia and the empire, the local quarrel being made the pretext for the settlement of minor outstanding claims of the Great Powers amongst themselves. The war was therefore a typical 18th century "war with a limited object," in which no one but the cabinets and the professional armies were concerned. It was fought on two theatres, the Rhine and Italy. The Rhine campaigns were entirely unimportant, and are remembered only for the last appearance in the field of Prince Eugene and Marshal Berwick—the latter was killed at the siege of Philippsburg—and the baptism of fire of the young crown prince of Prussia, afterwards Frederick the Great. In Italy, how-

ever, there were three hard-fought—though indecisive—battles, Parma (June 29, 1734), Luzzara (Sept. 19, 1734) and Bitonto (May 25, 1735), the first and last won by the Austrians, the second by the French and their allies. In Poland itself, Stanislaus, elected king in Sept. 1733, was soon expelled by a Russian army, and was afterwards besieged in Danzig by the Russians and Saxons (Oct. 1734–June 1735).

POLITIAN (1454–1494). Angelo Ambrogini, known in literary annals as Angelo Poliziano or Politianus from his birthplace, was born at Montepulciano in Tuscany on July 14, 1454. His father, Benedetto, a jurist of good family and distinguished ability, was murdered by political antagonists for adopting the cause of Piero de' Medici in Montepulciano, this circumstance gave his eldest son, Angelo, a claim on the family of Medici. At the age of ten he boy came to study at Florence, where he learned Latin under Cristoforo Landino, and Greek under Argyropoulos and Andronikos Kallistos. From Marsilio Ficino he imbibed the rudiments of philosophy. His genius for scholarship and poetry was early manifested. At 13 years of age he began to circulate Latin letters, at 17 he sent forth essays in Greek versification, at 18 he published an edition of Catullus. In 1470 he won for himself the title of *Homericus juvenis* by translating four books of the *Iliad* into Latin hexameters. Lorenzo de' Medici, who was then the autocrat of Florence and the chief patron of learning in Italy, took Poliziano into his household, made him the tutor of his children, and secured him a distinguished post in the University of Florence. Before he reached the age of 30, Poliziano expounded the humanities with almost unexampled lustre even for that epoch of brilliant professors. Among his pupils could be numbered the chief students of Europe, the men who were destined to carry to their homes the *spolia opima* of Italian culture. Not to mention Italians, it will suffice to record the names of the German Reuchlin, the English Grocyn and Linacre, and the Portuguese Tessiras.

Poliziano published the notes of his courses on Ovid, Statius, the younger Pliny, Quintilian, and the writers of Augustan histories. He also undertook a recension of the text of the *Pandects* of Justinian, which formed the subject of one of his courses, and this recension, though it does not rank high in the scale of juristic erudition, gave an impulse to the scholarly criticism of the Roman code. His versions of Epictetus, Herodian, Hippocrates, Galen, Plutarch's *Eroticus*, and Plato's *Charmides* delighted contemporaries by a certain limpid fluency of Latin style and grace of manner which distinguished him also as an original writer. Of these learned labours the most universally acceptable to the public of that time were a series of discursive essays on philology and criticism, first published in 1489 under the title of *Miscellanea*. They had an immediate, a lasting and a wide renown, encouraging the scholars of the next century and a half to throw their occasional discoveries in the field of scholarship into a form at once so attractive and so instructive. Poliziano was not, however, contented with these simply professional and scholastic compositions. Nature had endowed him with literary and poetic gifts of the highest order. These he devoted to the composition of Latin and Greek verses, which count among the best of those produced by men of modern times in rivalry with ancient authors. The *Manto*, in which he pronounced a panegyric of Virgil; the *Ambra*, which contains a beautiful idyllic sketch of Tuscan landscape, and a studied eulogy of Homer, the *Rusticus*, which celebrated the pleasures of country life in no frigid or scholastic spirit; and the *Nutricia*, which was intended to serve as a general introduction to the study of ancient and modern poetry—these are the masterpieces of Poliziano in Latin verse, displaying an authenticity of inspiration, a sincerity of feeling, and a command of metrical resources which mark them out as original productions of poetic genius rather than as merely professorial lucubrations. Exception may be taken to their style, when compared with the best work of the Augustan or even of the Silver age. But what renders them noteworthy to the student of modern humanistic literature is that they are in no sense imitative or conventional, but that they convey the genuine thoughts and emotions of a born poet in

Latin diction and in metre moulded to suit the characteristics of the singer's temperament.

Poliziano's principal Italian works are the stanzas called *La Giostra*, written upon Giuliano de' Medici's victory in a tournament; the *Orfeo*, a lyrical drama performed at Mantua with musical accompaniment, and a collection of fugitive pieces, reproducing various forms of Tuscan popular poetry. *La Giostra* had no plan, and remained imperfect; but it demonstrated the capacities of the octave stanza for rich, harmonious and sonorous metrical effect. The *Orfeo* is a slight piece of work, thrown off at a heat, yet abounding in unpremeditated lyrical beauties, and containing in itself the germ both of the pastoral play and of the opera. The Tuscan songs are distinguished by a "rosate fluency," an exquisite charm of half romantic, half humorous abandonment to fancy, which mark them out as improvisations of genius. It may be added that in all these departments of Italian composition Poliziano showed how the taste and learning of a classical scholar could be engrafted on the stock of the vernacular, and how the highest perfection of artistic form might be attained in Italian without a sacrifice of native spontaneity and natural flow of language.

Beyond the sphere of pure scholarship and pure literature Poliziano did not venture. He was present, indeed, at the attack made by the Pazzi conspirators on the persons of Lorenzo and Giuliano de' Medici, and wrote an interesting account of its partial success. He also contributed a curious document on the death of Lorenzo de' Medici. Otherwise, his uneventful life was passed as a house-friend of the Medici, as the idol of the learned world, and as a simple man of letters to whom (with truly Tuscan devotion to the Saturnian country) rural pleasures were always acceptable. He was never married; and his morals incurred suspicion, to which his own Greek verses lend a plausible colouring. He died, half broken-hearted by the loss of his friend and patron Lorenzo de' Medici, on Sept. 24, 1494.

POLK, JAMES KNOX (1795–1849), 11th president of the United States, was born in Mecklenburg county, N. C., on Nov. 2, 1795. In 1806 he crossed the mountains with his parents and settled in what is now Maury county, Tennessee. He graduated from the University of North Carolina in 1818, studied law in the office of Felix Grundy (1777–1840) at Nashville, Tenn., in 1819–20, was admitted to the bar in 1820, and began to practise in Columbia, the county seat of Maury county. After two years of service (1823–25) in the State house of representatives, he represented his district in the National house of representatives from 1825–39. In the party conflicts which succeeded the presidential election of 1824 he sided with the Jackson-Van Buren faction, and soon became recognized as leader of the Democratic forces. He was speaker from 1835 until 1839, when he retired from Congress to become governor of Tennessee. His administration (1839–47) was successful, but he was unable to overcome the popular Whig movement of that period, and was defeated in 1841 and again in 1843. When the Democratic national convention met in Baltimore in 1844 he was mentioned as a possible candidate for the vice presidency, but was suddenly brought forward as a "dark horse" and selected to head the ticket. Finding it impossible under the two-thirds rule to nominate their candidate, the followers of Van Buren brought forward Polk, who was popular in the South, in order to defeat Lewis Cass and James Buchanan. George Bancroft, the historian, has asserted that this

suggestion came originally from him, and Gideon J. Pillow, Polk's intimate friend, did much to bring about the nomination.

The unequivocal stand of Polk and his party in favour of the immediate annexation of Texas and the adoption of a vigorous policy in Oregon contrasted favourably with the timid vacillations of Henry Clay and the Whigs. Polk was elected, receiving 170 electoral votes to 103 for his opponent Clay. In forming his cabinet he secured the services of James Buchanan of Pennsylvania as secretary of State, Robert J. Walker of Mississippi as secretary of the treasury, William L. Marcy of New York as secretary of war, and George Bancroft, then of Massachusetts, as secretary of the navy. There is no doubt that each of these men, and Bancroft in particular, influenced the policy of the administration, yet the historian, James Schouler, who has made a careful study of the Polk papers, is doubtless correct in saying that the president himself was "the framer of the public policy which he carried into so successful execution, and that instead of being led (as many might have imagined) by the more famous statesmen of his administration and party who surrounded him, he in reality led and shaped his own executive course." Bancroft's opinion is that Polk was "prudent, far-sighted, bold, exceeding any Democrat of his day in his undeviatingly correct exposition of Democratic principles."

The four chief events of President Polk's administration were the final establishment of the independent treasury system, the reduction of the tariff by the "Walker bill" of 1846, the adjustment of the Oregon boundary dispute with Great Britain by the treaty concluded on June 15, 1846, and the war with Mexico and the consequent acquisition of territory in the south-west and west. The first three of these were recommended in his first annual message, and he privately announced to Bancroft his determination to seize California. The independent treasury plan originated during Van Buren's administration as a Democratic measure, it had been repealed by the Whigs in 1841, and was now re-enacted. Protectionists contended that the tariff legislation of 1846 was in direct violation of a pledge given to the Democrats of Pennsylvania in a letter written by Polk during the campaign to John K. Kane of Philadelphia. Briefly summarized, this letter approves of a tariff for revenue with incidental protection, whereas the annual message of Dec. 2, 1845, criticizes the whole theory of protection and urges the adoption of a revenue tariff just sufficient to meet the needs of the Government, conducted on an economical basis. It is difficult to determine whether this was always his idea of incidental protection, or whether his views were changed after 1844 through the influence of Walker and the example set by Sir Robert Peel in Great Britain, or whether he was simply "playing politics" to secure the protectionist vote in Pennsylvania.

The one overshadowing issue of the time, however, was territorial expansion. Polk was an ardent expansionist, but the old idea that his policy was determined entirely by a desire to advance the interests of slavery is no longer accepted. As a matter of fact, he was personally in favour of insisting upon 54° 40' as the boundary in Oregon, and threw upon Congress the responsibility for accepting 49° as the boundary. He approved the acquisition of California, Utah and New Mexico, territory from which slavery was excluded by geographical and climatic conditions. Furthermore a study of his manuscript diary shows that he opposed the efforts of Walker and Buchanan in the cabinet, and of Daniel S. Dickinson (1800-66) of New York and Edward A. Hannegan (d. 1859) of Indiana, in the Senate, to retain the whole of Mexico, territory in which slavery might have thrived. At the close of his term (March 4, 1849) Polk retired to his home in Nashville, Tenn., where he died on June 15, 1849.

He was married in 1824 to Sarah Childress (1803-91).

See John S. Jenkins, *James Knox Polk* (1890), and L. B. Chase, *History of the Polk Administration* (1890), both of which contain documentary material, but are not discriminating in their method of treatment. George Bancroft contributed a good short sketch to J. G. Wilson's *Presidents of the United States* (1894). He made copies of the Polk manuscripts and was working upon a detailed biography at the time of his death in 1891. These copies, now deposited in the Public Library, New York city, contain a diary in 24 typewritten vols. They were used by James Schouler in his *Historical*

Briefs (1866), and by E. G. Bourne in an article entitled "The Proposed Absorption of Mexico in 1847-1848," published in the *Annual Report of the American Historical Association for 1899*, i. 157-169 (1900). Bourne discusses the part which Polk took in preventing the complete absorption of Mexico. See also the *Diary of James K. Polk 1845 to 1849* (1910) edit. by M. M. Quaise, R. T. Schuyler, "Polk and the Oregon Compromise of 1846," *Pol Sci Quart.*, vol. xxvi p. 443-461 (Lancaster, Pa., 1911), E. I. McCormac, *James K. Polk* (1912), J. S. Bassett, *The Southern Plantation Overseer as Revealed in His Letters* (1925). A Nevins, ed., *Polk: The Diary of a President, 1845-49* (1929). (W. R. Sme.)

POLK, LEONIDAS (1806-1864), American general, was born at Raleigh, N.C., on April 10, 1806. He was educated at West Point, but resigned his army commission six months after graduation to enter the Virginia Theological seminary. In 1831 he took orders in the Protestant Episcopal Church. In 1838 he became missionary bishop of the southwest, including Arkansas, Indian territory, Louisiana, Alabama and Mississippi; in 1841 he was consecrated bishop of Louisiana. His work in the church was largely of an educational kind, and he played a prominent part in the founding of the University of the South. At the outbreak of the Civil War in 1861, he accepted a commission in the Confederate army and no longer exercised his episcopal authority. His rank in the hierarchy and the universal respect in which he was held in the south, rather than his early military education, caused him to be appointed to the important rank of major general. He fortified the post of Columbus, Ky., the foremost line of defense on the Mississippi, against which Brigadier General U. S. Grant directed the offensive reconnaissance of Belmont in the autumn. In the following spring, Polk commanded a corps at Shiloh in the field army commanded by Albert Sidney Johnston and Beauregard. In Oct. 1862 he was promoted lieutenant general, and thenceforward he commanded one of the three corps of the army of Tennessee under Bragg and afterwards was in charge of the department of Alabama, Mississippi and East Louisiana. He was killed at Marietta, while reconnoitring near Pine Mountain, Ga., on June 14, 1864.

See W. M. Polk, *Leonidas Polk, Bishop and General* (new ed., 1915).

POLKA, a lively dance of Bohemian origin, which at one period (about the middle of the 19th century) enjoyed extraordinary popularity throughout Europe. It is danced to music written in 3/4 time. (See *FLANCO*.)

POLLACK (*Pollachius virens*), a fish that is distinguished from others of the cod genus by the long pointed snout, and the prominent lower jaw, without a barbel, the colour is greenish, with yellow markings. It ranges from Norway to the Mediterranean, but is most abundant southwards, it prefers rocky ground, and is piscivorous. It attains a weight of over 20 pounds.

POLLAUOLO, the name of the brothers Antonio and Piero, sons of the goldsmith, Jacopo Pollauolo, Florentines who contributed much to Italian art in the 15th century, and of Simone, architect, the nephew of Antonio.

ANTONIO (1429-1498) distinguished himself as a sculptor, jeweller, painter and engraver, and did valuable service in perfecting the art of enamelling. He was apprenticed to Bartoluccio Ghiberti, a goldsmith (step-father of the great Ghiberti). It was not until later that Antonio took to painting. His chief achievement in that art is the "Martyrdom of St. Sebastian" (1475) in the National Gallery, London, in the execution of which he was helped by his brother. Here, too, is the fine small panel of "Apollo and Daphne" in the Uffizi, Florence, is his "Labours of Hercules." He aimed, above all, at the representation of the human figure in action, and he ranked as the foremost draughtsman of his time. He is said to have been one of the first artists who had recourse to dissection in his anatomical studies. But it was as a sculptor and metal-worker that he achieved his greatest successes. The museum of Florence contains the bronze group, "Hercules strangling Cacus," and the terra-cotta bust, "The Young Warrior." In 1489 Antonio took up his residence in Rome, where he executed the tomb of Sixtus IV. (1493). He died on Feb. 4, 1498, having just finished his mausoleum of Innocent VIII. PIERO (1443-1496) was a painter, probably the pupil of Alesso Baldovinetti. His principal works were his "Coronation of the Virgin," an altarpiece painted in 1483, in the choir of the cathe-

dral at San Gimignano, his "Three Saints," an altarpiece, and "Prudence" are both at the Uffizi gallery

SIMONE (1457-1508) nephew of Antonio Pollaiuolo, a celebrated architect, was born in Florence and went to Rome in 1484, there he entered his uncle's studio and studied architecture. On his return to Florence he was entrusted with the completion of the Strozzi palace begun by Benedetto de Maiano, and the cornice on the façade has earned him lasting fame. His highly coloured accounts of Rome earned for him the nickname of *il Cronaca* (chronicler). About 1498 he built the church of San Francesco at Monte and the vestibule of the sacristy of Santo Spirito. In collaboration with Giuliano da Sangallo he designed the great hall in the Palazzo Vecchio. He was a close friend of Savonarola

POLLAN (*Coregonus pollan*), the only Irish fish of the genus *Coregonus*, with three forms inhabiting respectively Lough Neagh, Lough Erne and the Shannon. The jaws are equal in front. (See SALMONTIDAE)

POLLARD, ALBERT FREDERICK (1869-1948), English professor of history, was born at Ryde on Dec. 16, 1869, and educated at Jesus college, Oxford. He was elected a fellow of All Souls college, Oxford in 1898. From 1893 to 1901 he was assistant editor of the *Dictionary of National Biography*. From 1903 to 1931 he held professorial chairs of English history and constitutional history in the University of London. He was founder and first chairman of the Institute of Historical Research. He died Aug. 3, 1948, at Millford-on-Sea, Hampshire, Eng.

His publications include *Thomas Cromwell and the English Reformation* (1898, new ed. 1926), *Henry VIII* (1902), *Factors in Modern History* (1907, new ed. 1926), *Evolution of Parliament* (1902), *Factors in American History* (Cambridge, 1925)

POLLARD, ALFRED WILLIAM (1859-1944), English scholar, was born in London on Aug. 14, 1859, and educated at King's college school, London, and St John's college, Oxford. In 1884 he entered the British Museum as assistant in the department of printed books, of which he became assistant keeper in 1900, and keeper from 1919-24. In 1916 he was appointed Sanders reader in bibliography in Cambridge university, and in 1917 professor of English bibliography at King's college, London and held that chair until 1932

His publications include *Bibliographica* (1894-96), *Early Illustrated Books* (1895), *An Essay on Colophons* (1905), *Shakespeare's Folios and Quartos* (1909), *A New Shakespeare Quarto* (Richard II 1568) (1916), *A Short Title Catalogue of English Books* (1475-1640), with G. R. Kedwards and others (1926)

POLLENTIA, an ancient town of Liguria, Italy, 10 mi. to the north of Augusta Bagiennorum, on the left bank of the Tanarus. Its position on the road from Augusta Taurinorum to the coast at Vada Sabatia, at the point of divergence of a road to Hasta (Asti) gave it military importance. Decimus Brutus managed to occupy it an hour before Mark Antony in 43 B.C., and it was there that Stilicho on March 29, 403, fought the battle with Alaric which though undecided, led the Goths to evacuate Italy. Considerable remains of ancient buildings still exist.

POLLINATION, a term used in botany for the transference of pollen (see FLOWER) to the stigma (the receptive surface) of the ovary of the flower. Such pollination brings about the fertilization of the ovules in the ovary and their subsequent development into seeds, there are, however, a few cases in which parthenogenesis occurs, i.e., the ovules develop without fertilization. As the pollen-bearing parts of the stamens are rarely in contact with the stigma at the time when both of these are ripe, some mechanism is clearly necessary to bring the pollen to the stigma. The means in question is usually wind or insects, though sometimes other agencies such as water or birds may be responsible. The great variety in the form, colour and scent of flowers has been developed in relation to the particular agency of insects. Apart from the mechanism of pollination we can distinguish two types—self-pollination (autogamy) in which pollen is transferred from the stamens of one flower to the stigma of the same flower, and cross-pollination (allogamy) in which pollen is transferred to

the stigma of another flower on the same plant (geitonogamy) or to the flower of another plant of the same species (xenogamy). Occasionally hybridization is possible, the pollen of one plant bringing about fertilization of the ovary of the flower of another species or, more rarely, of the flower of a plant belonging to another genus, cases of hybridization between genera are known for example in *Cyads* (see GYMNOSPERMS) and in orchids

Cross-Pollination and Dichogamy—Cross-pollination is the only possible method in the case of unisexual flowers whether the plant is *monoecious* (i.e., with staminate and pistillate flowers on the same plant), as in birch, beech, elder, oak, or *dioecious* (i.e., with staminate and pistillate flowers on different plants) as in the case of willows and poplars. In hermaphrodite flowers bearing both stamens and carpels, either self-pollination or cross-pollination can occur. It is interesting to note, however, that many flowers have special arrangements to ensure that the pollinating mechanism, whatever it may be, causes cross-pollination and not self-pollination. One of the commonest methods to achieve this is a separation in time of the sexes—the stamens dehiscence and shed their pollen either before or after the stigma is receptive. This separation in time—and it may apply to the separate male and female flowers on the same plant—is known as *dichogamy*. When the stamens ripen first it is known as *protandry*, the more common case while when the stigma is ready first, it is known as *proterogyny*. Protandry is very common in insect-pollinated (*entomophilous*) flowers, as in nearly all members of the Compositae (*q.v.*) and Umbelliferae, many Labiatae (such as dead-nettle [*Lamium*] and *Salvia*), the Caryophyllaceae, the large willow-herb (*Epilobium angustifolium*), etc. Proterogyny is found in the horsechestnut (*Aesculus*) the autumn crocus (*Colchicum*), many Araceae, and in wind-pollinated anemophilous flowers such as plantain (*Plantago*) meadow rue (*Thalictrum*) and many grasses, though here separation in time is very short and many are self-pollinating, such as wheat, barley and oats. It is often accepted that cross-pollination is of greater value to the plant than self-pollination in respect of weight and number of seeds, the question is, however, one of some difficulty. The numerous provisions in flowers for aiding cross-pollination and hindering self-pollination suggest the superiority of the former process, but there are numerous plants which normally and for generative are self-pollinated

WIND POLLINATION (ANEMOPHILY)

The method of pollination of the earlier and more primitive flowers was probably by the wind, the insect-pollinated flowers being derived from them in later stages of evolution. Some flowers such as plantain and meadow rue mentioned above, are almost certainly anemophilous by reduction, all their congeners being entomophilous, other cases are *Potterium* among the Rosaceae and Kerguelen's Land cabbage (*q.v.*) among the Cruciferae

Characters of Anemophilous Flowers—These are such as might be expected. The flowers are usually inconspicuous (the corolla being commonly absent) for there is no advantage in their being easily seen and they are without the scent or nectar so common in flowers visited by insects. Furthermore there is usually no tubular formation of the flower and no irregularities. On the other hand these wind-pollinated flowers form large quantities of pollen, since the greater proportion when consigned to the air must necessarily be lost. The large quantity of pollen produced by pines and other conifers is well known, in these plants the numerous stamens are massed in male cones often of considerable size, though smaller than the female cones. In other families, such as the grasses, Cyperaceae, Urticaceae, the number of stamens in each flower is small but the anthers are large. Again, in these flowers the pollen is dry and powdery and does not stick together in small masses as in entomophilous flowers, this enables the pollen to blow about easily. The pollen in this type of flower must be easily removed by the wind, the absence of floral envelopes facilitates this and so do the pendulous catkins (hazel, plane, etc.) which can sway in the wind. In addition the filament of the stamen is usually long so that the anthers hang out of the

flower, and are also versatile (see FLOWER) so that the pollen is easily shaken from them.

Another common characteristic of the flowers in question is that the stigma is much larger and rougher than that of entomophilous flowers and it is freely exposed to the air so as to increase the chance of reception of the pollen, in maize, for example, the stigma is of very great length. In many catkin-bearing plants the flowering stage occurs before the leaves appear, so that accidental interception of pollen by the leaves is avoided. As already stated dichogamy is quite common in anemophilous flowers but protogyny is much more common than protandry.

INSECT POLLINATION (ENTOMOPHILY)

The special characteristics of entomophilous flowers are the attractive colour of the floral envelope, the presence of scent and of nectar, and of pollen which is not powdery but sticky and is present in comparatively small quantities. The entomophilous is the most common type of pollination in flowering plants and special floral conformations and irregularities adapted to insect visitors are characteristic of the higher families of flowering plants, as will be seen below. The evolution of flowers and of insects must have gone hand in hand, such groups as *Lepidoptera* (butterflies and moths) and *Hymenoptera* (bees, wasps, etc.) could not have existed without the more elaborate and honey-bearing flowers and *vice versa*. Hermann Müller (see *Bibliography*) has divided flowers into various classes according to their degree of specialisation for different insects, so that a brief survey of the types of insects concerned must be given.

Types of Insects.—There are five important classes of insects which visit flowers. The *Hemiptera* (bugs, etc.) have a few flower-visiting species but they show no special adaptation to flowers, the *Coleoptera* (beetles) have many species which visit flowers but they have only short tongues (only a few species with a length of 3 to 6 mm.) and so are able to reach only honey which is fully exposed. The *Diptera* (flies) include many species which visit flowers. The *short-tongued* ones (with tongues under 4 mm.) show no special adaptation to a diet of floral origin and are not usually clever enough to find any nectar which is not fully exposed in the flower, many of these flies have also other sources of feeding. The *long-tongued* flies (such as hover flies or drone flies) have tongues from 4–12 mm. and confine themselves to a diet of nectar, and are clever in discovering it when concealed. The *Hymenoptera* (bees, wasps, sawflies, ants, etc.) include a very large number of flower-visiting forms. Bees are the only long-tongued members of the group, and it is bees which have played the most important part in the evolution of the more complex flowers. The hive bee (*Apis*) and the humble-bee (*Bombus*) have long tongues (over 6 mm.) while most of the other bees have shorter tongues, i.e., less than 6 mm. The "cleverness" of bees, combined with the length of their proboscis, enables them to find and reach nectar which is deeply concealed in the flower. Bees do not confine themselves to sucking nectar from the flower; they also collect pollen (some flowers provide only pollen and no nectar), which is carried in small masses attached to the hairs of the hind legs. The *Lepidoptera* (butterflies and moths) are insects with tongues usually about as long as those of bees, but the hawk moths may have tongues, when unrolled, of enormous length. The British hawk moth, *Sphinx conovalis*, has a tongue 80 mm. ($\frac{3}{4}$ in.) long and some tropical moths a tongue of 300 mm. ($12\frac{1}{2}$ in.).

Classes of Flowers.—The entomophilous flowers have been divided by H. Müller into nine classes based on the structure of the flower and its relation to particular insects.

(i.) Class A. *Flowers with Exposed Nectar*.—In this class come most Umbelliferae, many Saxifragaceae, the bedstraws (*Galium*), ivy (*Hedera*) and such trees as maple, elder and lime. The flowers are wide open and usually small and the visitors are mostly short-tongued; they are rarely visited by bees and butterflies. Such flowers run the risk of the nectar being washed away by rain.

(ii.) Class AB. *Flowers with Partially Concealed Nectar*.—In this class fall the buttercups (*Ranunculus*), the Cruciferae, the strawberry (*Fragaria*) and the willows (*Salix*). The nectar is

protected and concealed by the position of the stamens, by the development of hairs or scales, or by the flower being partially tubular, as in wallflower where the sepals stand erect and give a tubular form to the lower part of the flower.

(iii.) Class B. *Flowers with Fully Concealed Honey*.—In this class are the flowers of many Carophyllaceae (such as *Gypsophila*, *Geranium*), *Polemonium*, blackberry (*Rubus*), eyebright (*Euphrasia*) mint (*Mentha*), heather (*Calluna*). In these the nectar may be concealed by the stamens, by the calyx, by the receptacle becoming hollowed, or by the petals being united to form a symmetrical corolla. The insect visitors are the smaller bees with a few of the longer tongued flies. This type of flower is clearly the most effective of the classes so far mentioned. The bees show a high degree of skill in reaching the concealed honey and mostly confine themselves during a single flight to one or a few species of flower, and thus avoid the great waste of pollen caused by shorter tongued insects, which are liable to carry it indiscriminately from the flower of one species to another.

(iv.) Class B' is an extension of Class B and includes the flowers of the Compositae, most Dipsacae and some Campanulaceae, in which the flowers have the same length of tube, etc., as Class B, but are aggregated into an inflorescence, which by the untrained might be mistaken for a flower, and which acts like a single flower as a unit of attraction.

(v.) Class F. *Lepidoptera Flowers*.—This includes those flowers in which the floral tube has been so deepened that short-tongued insects are excluded altogether and in many cases only *Lepidoptera* can reach the nectar. The alpine moss campion (*Silene acaulis*), for example, is adapted to butterflies, while the bladder campion (*S. inflata*) is adapted to moths and emits a scent at night. To the latter class belong also the honeysuckle (*Lonicera*), tobacco plant (*Nicotiana*), evening primrose (*Oenothera*), and night-scented stock and many others.

(vi.) Class H. *Bee Flowers*, are those which are visited mostly by long-tongued bees, the depth of the tube being 6 to 15 mm. The flowers are also often markedly zygomorphic (i.e., having a special kind of irregularity, see FLOWER), providing a landing place for the bee, others are of such a shape that (as in the snapdragon and broom) it requires an insect like the humble-bee which is not only "clever" but of considerable size and weight in order to open the flower.

(vii and viii) The D and K classes of flowers include those adapted to small insects, they are pollinated by flies, beetles and small bees.

Lastly, there is (ix) the Class Po, *Pollen Flowers*. These provide no nectar, but abundant pollen for which the flower is visited, mainly by bees, examples are *Clematis*, meadowsweet (*Spiraea*), rock rose (*Helianthemum*), dog rose (*Rosa canina*), poppy. In some flowers, such as *Cassia*, some stamens provide "food-pollen" for insects, other stamens supply the fertile pollen for fertilization.

Nectar, Colour and Scent.—Nectar is a watery fluid secreted by certain parts of the flower and sometimes by other parts of the plant, as in the case of the extra-floral nectaries. It contains a sugar (glucose) sometimes to as much as 25%. It is from the nectar that the bee makes honey, which is a manufactured product with nectar as the raw material. As has already been indicated the position of the nectaries (the nectar-secreting glands) is very various, they may be fully exposed or hidden and deeply enclosed. In some cases the nectar is secreted by one organ and collected in another as in *Viola*, where it collects in the spur but is secreted by appendages of the stamens. In other cases there is no free nectar but the insect must pierce with its proboscis the juicy, sapid cells, which in the case of some orchids line the spur.

The importance of colour in attracting the attention of insects is obvious, but it does not follow that the flowers most striking or attractive to our eyes are those most conspicuous or alluring to the insect. The problem of the colour-sense of insects has been investigated by a number of workers and it seems clear that bees at least can distinguish some colours, such as blue and yellow, and do not merely depend on the different brightness between, say, a deep purple flower and a light yellow one. In the different flower classes (A to H) already defined there is a tendency to a progres-

sion in colour, the simpler flowers in the A and AB classes tend to be white or yellow, while in the B class blues and purples are found. In class H, the bee flowers, blues and purples predominate, while in class F, the butterfly and moth flowers, pale tints of pink and purple are most common. The special colour markings on flowers, such as the yellow eye of forget-me-not (*Myosotis*), the darker lines on the petals of the violet and pansy, appear to assist the insect to find the nectar and are known as honey guides.

Scent is obviously of great importance and the olfactory sense of some insects such as moths is very much greater than ours. J. H. Fabre showed that moths when out of sight of honeysuckle would fly straight to it from a distance of several hundred yards. K. van Frisch has investigated elaborately the olfactory sense of the honey bee. Bees which had been drilled by association of oil of orange with sugar could pick out this scent from 43 other ethereal oils. As stated by M. Skene (see p. 172) the general conclusion is "that colour is the guide to the flower, and that scent is useful in enabling the bee, flying among the many flowers of similar colour, to pick out the species it has formed the temporary habit of visiting." In this it is helped by the sense of form.

SPECIAL MECHANISMS OF ENTOMOPHILOUS FLOWERS

Pollination of Sage.—Such a plant as the sage (*Salvia pratensis*) has a typical humble-bee flower. The bee alights on the platform formed by the lower lip of the sympetalous corolla and pushes its head down the tube to reach the nectar at the bottom. Each of the two stamens is of special shape, the connective is very large and two-armed, and is hinged to the short filament. The longer arm bears a half anther while the short arm is sterile, the whole stamen having a lever mechanism. The bee, in probing for the honey, comes in contact with the short arm of the lever and in pressing this down brings the half anther at the end of the longer arm down upon its back where the pollen becomes deposited. The flower is protandrous and in a later stage the style elongates and is brought into the same position as occupied by the back of the bee when in contact with the anther. Cross pollination is thus brought about when the bee passes from a younger to an older flower.

Papilionaceous Type.—The Leguminosae (Pea family) show a very interesting series of pollination mechanisms. In this familiar type of flower to which the pea and gorse belong, the essential parts of the flower are enclosed in the keel. The nectar is secreted by the inner sides of the lower part of the staminal tube, one of the ten-stamens is usually free and at its base are two openings leading to the nectar. The nectar is thus not only carefully concealed but is also at a considerable depth. Cleverness and length of proboscis are thus required so that as might be expected these flowers are bee flowers. An insect visiting the flower alights on the wings, thus depresses them and, as they are joined to the keel, this is depressed also. The stigma and stamens are thus forced out, the stigma usually first so that it has the chance of brushing off pollen from the under-side of the bee and thus being cross pollinated.

There are four different types (1) Flowers in which the stamens and stigma return within the keel so that repeated visits are possible, examples are the clovers, melilot (*Melilotus*) and laburnum. (2) Flowers that are explosive, since the style and stamens are confined under tension in the keel and when it is depressed they are released with suddenness, thus scattering pollen on the undersurface of the bee. Only one insect visit is thus effective. Examples are broom (*Gonista*), gorse (*Ulex*), lucerne (*Medicago*). (3) Flowers which display a *piston mechanism*—the pollen is shed early and the heads of the five outer stamens act as a piston so that the weight of the bee on the keel squeezes a narrow ribbon of pollen through the pore at the apex of the keel. A further pressure causes a protrusion of the stigma which is thus brought in contact with the bee. Examples are lupin (*Lupinus*), rest harrow (*Ononis*) and bird's foot trefoil (*Lotus corniculatus*). (4) Flowers which show a *brush mechanism*, for the pollen is again shed early and the style, which is provided with a brush of hairs, sweeps the pollen in small portions out of the tip of the keel. Flowers of this type usually allow of repeated insect visits.

Pinch Trap Flowers.—This type of flower is found in the Asclepiadaceae. The pollen is massed together into pollinia and pairs of these are attached to a sort of clip in which the leg of the insect (bees, wasps, etc.) becomes caught. The pollinia are thus carried away to another flower and are likely to come in contact with its stigmatic surface. *Pitfall flowers* are shown by the cuckoo plant (*Arum maculatum*), a common British plant, and by *Aristolochia* and *Asarum*. In *A. maculatum* there is a spathe surrounding a spadix which bears a fringe of stiff downwardly projecting hairs at the top. These hairs allow the entry of insects but not their return, the insects are thus trapped for a time in the spathe and pollinate the pistillate flowers, later the hairs wither and exit becomes possible. Flies are the common visitors.

Piston Mechanism of Compositae.—The flowers of this family show a very efficient pollination mechanism which, with the economy of material resulting from the massing of the flowers into heads and the effective method of seed dispersal, probably explains the dominant position of the family.

Pollination of Fig.—The fig shows a very remarkable inter-relationship between an animal and plant. The flowers in the fig are unisexual and are borne in numbers together on the inside of the hollow inflorescence, which opens to the outside by a pore. The swollen and fleshy infructescence (as the inflorescence becomes) is the edible fruit, each "seed" being the product of a single flower and in reality a fruit. The female of a small wasp (*Blastophaga*) enters the inflorescence and deposits eggs in special "gall flowers" incapable of setting seed. The larvae are hatched out and undergo metamorphosis. The male wasps fertilise the female and then die without leaving the inflorescence. The female wasps leave the gall flowers and crawling out through the pore become dusted with pollen from the male flowers in the neighbourhood of the pore. They then enter other figs and pollinate the female flowers, which set seed. The fig and wasp are thus mutually dependent. When *Smyrna* figs were introduced into California it was found necessary to introduce the capring (non-edible fig) containing the wasp *Blastophaga*.

Pollination of Yucca.—This is another case of the complete interdependence of a flower and a moth. The large white flowers of this plant emit their perfume especially at night and are visited by a moth (*Promilia yuccasella*). The female moth (see *Yucca-moth*) collects pollen from the anthers of the flower and kneads it into a pellet about three times the size of its head. It flies to another flower and, piercing the ovary wall with its long ovipositor, lays a few eggs between the ovules. After this it climbs down the style of the hanging flower and presses the ball of pollen into the stigma; by this means fertilisation is ensured. Only a certain proportion of the seeds are destroyed by the developing insects, which, when mature, eat through the fruit wall, drop to the ground and remain dormant in a cocoon until the next flowering season, when the moth emerges. This seems to be the only method of pollination, for in the absence of the moth the plant is said to be completely sterile.

Pollination of Orchids.—The orchids show many and complicated adaptations to pollination by insects. A great impetus to their study was given by the publication in 1862 of Darwin's monograph on the various pollination mechanisms exhibited by this group. As is well known, in this flower there is generally only one stamen, which is two-lobed, and the pollen is in the form of two stalked masses, the pollinia which the insect carries away stuck to its head. As the insect flies away, the pollinia, if not already properly oriented, execute such a movement as brings them into position to touch the stick stigma of the next flower that is visited. There are, however, a great many variations in the details of this process. Nectar is not usually secreted by the orchid flower, but to obtain a sweet juice the insect has to pierce a special tissue, usually that of the labellum (the posterior petal), which is often spur-like.

Heterostylism.—In some cases the plant bears more than one type of flower. The primrose (*Primula vulgaris*) and the cowslip (*P. versis*) are dimorphic, i.e., some plants have flowers with a long style bearing a knob-like stigma at the mouth of the corolla tube and the five stamens stand half-way down the tube; in others

the flower has a short style with a stigma half-way down the tube while the stamens stand at the top. These two types of flower are known as "pin-eyed" or long-styled and "thrum-eyed" or short styled, respectively. From their correspondence in position, the insect tends to transfer pollen from the thrum-eyed to the stigma of the pin-eyed and *vice versa*. These two types of pollination are spoken of as "legitimate," and Darwin showed that this type produces more seed and more vigorous progeny than "illegitimate" pollination of thrum-eyed stigma by thrum-eyed pollen or pin-eyed stigma by pin-eyed pollen. In trimorphic plants such as the loose-strife (*Lythrum Salicaria*), there are three types of flower, short-styled, long-styled and those with styles of intermediate length. In each type the stamens are in two groups of different lengths, in the first type the stamens are long and intermediate, in the second type they are short and intermediate, and in the third they are short and long. Eighteen possible methods of pollination are possible, six being "legitimate" and 12 "illegitimate." Legitimate unions are found to yield a larger amount of seed than illegitimate

POLLINATION BY AGENCIES OTHER THAN WIND AND INSECTS

In some water plants the pollen is brought to the stigma by the agency of water. In *Najas* the pollen grains sink in the water and are caught by the stigma. In the eel-grass (*Zostera*), the American water-weed (*Elodea canadensis*), and others, the pollen floats on the surface and so reaches the female flowers. In *Vallisneria*, the male and female flowers are on separate plants and the male becoming detached and floating free on the surface of the water, may reach and become entangled with the fixed larger female flowers, with the result that the anthers come in contact with the projecting stigmas.

In some cases animals other than insects are responsible for pollination. In some countries pollination by birds (humming birds, honey-suckers and sun birds) plays a considerable part. These ornithophilous flowers, as they are called, are not very different from insect flowers, many bird flowers being also visited by insects. A landing place is, however, not necessary, as the birds sip the nectar while hovering. The flowers are scentless, and the styles, stigma and filament often rigid. The colour red seems to be predominant in flowers of this type. Examples of ornithophilous flowers are *Sirechsea regina* in South Africa, species of *Salvia* and *Erythrina* in South America. In Java, species of *Freyinetia* and in Trinidad *Bauhinia megalandra*, are said to be pollinated by bats.

SELF POLLINATION (AUTOGAMY)

Self pollination is effected in various ways. In the simplest case the anthers are close to the stigmas, covering these with pollen when they open; this occurs in a number of small annual plants, also in *Narcissus*, *Crocus*, etc. In snowdrop and other pendulous flowers the anthers form a cone around the style and the pollen falls on to the underlying stigmas, or in erect flowers the pollen may fall on to the stigmas which lie directly beneath the opening anthers (e.g., *Narthecium*). In very many cases the pollen is carried to the stigma by elongation, curvature or some other movement of the filament, the style or stigma, or some other part of the flower, or by correlated movements of two or more parts. For instance, in many flowers the filaments are first directed outwards so that self pollination is not possible, but later incline towards the stigmas and pollinate them (e.g., numerous Saxifragaceae, Cruciferae and others), or the style which first projects beyond the anthers, shortens later on, so that the anthers come into contact with the stigmas (e.g., species of Cactaceae); or the style bends so that the stigma is brought within the range of the pollen (e.g., species of *Oenothera*, *Epilobium*, most Malvaceae, etc.) In *Mirabilis jalapa* and others the filaments and styles finally become intertwined, so that pollen is brought in contact with the stigma. Self-pollination frequently becomes possible towards the end of the life of a flower which during its earlier stages has been capable only of cross-pollination. This is well seen in the case of the flowers of the Compositae, where the stigma lobes later bend round and come in contact with the pollen held by the brush of the style below.

Cleistogamy.—The extreme case of autogamy is that of cleistogamous flowers which must necessarily be self-pollinated. The sweet violet (*Viola odorata*), the wood sorrel (*Oxalis acetosella*), *Lamium amplexicaule* and other British plants bear, in addition to the ordinary flowers, small bud-like flowers (cleistogamous flowers) which never open. The pollen germinates in the anthers and the pollen tubes pierce the walls and so reach the stigmas and the ovules are fertilised. Some plants such as *Salvia cleistogama* produce only cleistogamous flowers.

BIBLIOGRAPHY.—The classical compendium on flower pollination in English is P. Knuth, *Handbook of Floral Pollination* (Oxford, 1900, original German edition, 1898-1905), where a great mass of data is brought together. Good brief reviews of the subject are given in M. Skene, *The Biology of Flowering Plants* (1914), Kerner and Oliver, *The Natural History of Plants* (1895), the earlier editions (e.g., the 2nd of 1904) of J. C. Willis, *A Dictionary of Flowering Plants*. Most text books of botany give some review of the subject. The earliest work on the subject was C. K. Sprengel's book entitled *Das entdeckte Geheimnis der Natur im Bau und in der Befruchtung der Blumen* (Berlin, 1793); Sprengel's first observation in this field was that of the presence of hairs in the throat of the corolla of a species of *Geranium*, which, he concluded, were for the purpose of preventing the nectar being washed out by rain, from this he was led on to consider the function of corolla markings such as the yellow centre of forget-me-not which he interpreted as honey guides to the insects. For the distinction of flower classes see H. Muller, *The Fertilisation of Flowers* (London, 1883). For the colour sense and olfactory sense of bees see K. von Frisch, *Der Farben- und Geruchssinn der Biene* (Jena, 1914) and *Über den Geruchssinn der Biene* (Jena, 1919). For a review of ornithophilous flowers see F. Werth, "Kürzer Überblick über die Gesamtfrage der Ornithophilie," *Bot. Jahrb.* (1915) (V. H. B.).

POLLIO GAIUS ASINIUS (76 B.C.-A.D. 5, according to some, 75 B.C.-A.D. 4), Roman orator, poet and historian. In 54 he impeached unsuccessfully C. Porcius Cato. In the civil war Pollio sided with Caesar, was present at the battle of Pharsalus (48), and commanded against Sextus Pompeius in Spain. He subsequently threw in his lot with M. Antonius, for whom he governed *Galicia Transpadana*. In superintending the distribution of territory amongst the veterans, he saved Virgil's property from confiscation. In 40 he helped to arrange the peace of Brundisium by which Octavian (Augustus) and Antonius were for a time reconciled. In the same year he was consul, it was now that Virgil addressed the famous fourth eclogue to him. Next year Pollio conducted a successful campaign against the Parthians, an Illyrian people who adhered to Brutus, and celebrated a triumph on Oct. 25. From the spoils of the war he constructed the first public library at Rome, in the Atrium Libertatis, also erected by him (Pliny, *Nat. hist.* xxv. 10). Thereafter he withdrew from active life and devoted himself to literature. He seems to have maintained an attitude of independence, if not of opposition, towards Augustus. He died in his villa at Tusculum, regretted and esteemed by all.

Pollio was a distinguished orator, his speeches showed ingenuity and care, but were marred by an affected archaism (Quintilian, *Inst.* x. 1. 113; Seneca, *Ep.* 100). He wrote tragedies also, which Virgil (*Eccl.* viii. 10) declared to be worthy of Sophocles, and a prose history of the civil wars of his time from the first triumvirate (60) down to the death of Cicero (43) or later. His writings are lost except a few fragments of his speeches (H. Meyer, *Orat. rom.* frag. 1842), and three letters to Cicero (*Ad. Fam.* x. 31-33).

See Plutarch, *Caesar*, *Pompey*, *Vell. Pat.* ii. 36, 63, 73, 76, *Florus* iv. 12, 17, *Di. Cassius* xiv. 10, xlviii. 15; Appian, *Bell. civ.* v. Gardthausen, *Augustus und seine Zeit* (1897), 1. P. Groebe, in Pauly-Wessowa's *Realencyclopädie* (1896), ii. pt. 2; Teuffel-Schwaben, *Hist. of Roman Literature* (Eng. trans.), § 221; M. Schanz, *Geschichte der römischen Literatur*, pt. 2, p. 20 (2nd ed. 1899); Cicero, *Letters*, ed. Tyrrell and Purser, vi. intro. p. 80, E. D. Pierce, *A Roman Man of Letters* (New York, 1922).

POLLOCK, the name of a great English legal family. The well-known members are SIR JONATHAN FREDERICK POLLOCK (1783-1870), chief baron of the exchequer. Born on Sept. 23, 1783 in London, the son of David Pollock, saddler, of Charing Cross, he was educated at St. Paul's and Trinity college, Cambridge, and was called to the bar in 1809. He took silk in 1827, and in 1831 was member of parliament for Huntingdon. He was

attorney-general in 1834, and again in 1841, in 1844 he succeeded Abinger as chief baron of the exchequer, and sat until 1866, when he retired. He died at Hatton, Middlesex, on Aug. 23, 1870. His greatest judicial triumph was in *Egerton v. Brownlow*.

See Sir F. Pollock (2nd Bart.) *Personal Remembrances* (1887).

SIR FREDERICK POLLOCK (1845-1937), born on Dec. 10, 1845, was educated at Eton and Trinity college, Cambridge. He was called to the bar in 1871, and was Corpus professor of Jurisprudence at Oxford, 1883-1903. He was made a Privy Counsellor in 1911 and in 1914 became judge of the admiralty court of Cinque ports. In 1920 he was made a King's Counsel. His legal textbooks are standard, he wrote certain legal articles for the *Encyclopaedia Britannica*. He edited the *Law Quarterly Review* from 1885 to 1919 and was Editor of the *Law Reports*, 1895-1935.

His works include *Principles of Contract* (1876, 9th ed. 1911), *Digest of the Law of Partnership* (1877, 12th ed. 1930), *The Law of Torts* (1887, 13th ed. 1929), *Possession in the Common Law* (with Sir R. S. Wright, 1888), *History of English Law* (with Prof. F. W. Maitland, 1895, 2nd ed. 1898), *Selden's Table Talk* (for Selden Society, 1927), *Spencer, his Life and Philosophy* (1880, 2nd ed. reissued with additions, 1912), etc.

POLLS, PUBLIC OPINION: see PUBLIC OPINION SURVEYS.

POLL TAX. A tax of a uniform amount levied on each individual, a tax of so much per head (middle English *poll*, a head). By mid-20th century this tax had long been abandoned by most countries and was not an important revenue raiser in any tax system in the world.

The most famous poll tax in English history is the one levied in 1380, which led to the revolt of the peasants under Wat Tyler in 1381, but the first instance was in 1377, when a tax of a great head was voted by both clergy and laity. In 1379 the tax was again levied, but on a graduated scale. John of Gaunt, duke of Lancaster, paid ten marks and the scale descended from him to the peasants, who paid one great each, every person over 16 years of age being liable. In 1380 the tax was also graduated, but less steeply. For years after the rising of 1381 money was raised in this way only from aliens, but in 1513 a general poll tax was imposed. This produced only about £50,000, instead of £160,000 as was expected, but a poll tax levied in 1641 resulted in a revenue of about £400,000. During the reign of Charles II, money was obtained in this way on several occasions. For years after 1688 poll taxes were a favourite means of raising money for the prosecution of the war with France.

Although a few U.S. states at mid-20th century still levied the tax for revenue purposes only, most discussion of the tax centred around its use as a voting prerequisite in the southern states. Ten southern states made the poll tax a voting prerequisite between 1890 and 1902, an 11th, Georgia, had enacted the requirement many years earlier. In its origins the tax is associated with the agrarian unrest of the 1880s and 1890s, which culminated in the rise of the Populist party in the west and the south. The Populists, a low-income farmers' party, gave the Democrats the only serious competition they had experienced since the end of Reconstruction. The intensity of competition led both parties to bring the Negro back into politics and to compete for his vote. Once the Populists were defeated the Democrats amended their state constitutions or drafted new ones to include various disfranchising devices. The poll tax was one of these. Its purpose was to disfranchise Negroes and possibly also to weaken politically the poor whites who had made up the backbone of the Populist party.

After 1920 the poll tax was abolished by state action in North Carolina, Louisiana, Florida, Georgia, South Carolina and Tennessee. Constitutional amendments to wipe out the tax were submitted to the voters in Arkansas, Virginia and Texas, but failed to pass. The tax still prevailed in these states as well as in Alabama and Mississippi at mid-century; the rate ranged from \$1 to \$4 per year. In Texas and Arkansas, failure to pay merely disfranchised a person for that year only and did not create an obligation which must be paid in subsequent years if he wished to vote. In Virginia and Mississippi the tax was in some degree cumulative, and in Alabama it was possible to run up a bill of as much as \$36 in delinquent poll taxes which would have to be paid

in order to vote.

(R. S. S., X.)

POLLUX, JULIUS, of Naucratis in Egypt, Greek grammarian and sophist of the 2nd century A.D. He taught at Athens, where, according to Philostratus (*Vit. Soph.*), he was appointed to the professorship of rhetoric by the emperor Commodus on account of his melodious voice. His only surviving work is the *Onomasticon*, a Greek dictionary in ten books, which supplies much rare and valuable information on classical antiquity.

The chief editions of the *Onomasticon* are those of W. Dindorf (1824), with notes of previous commentators, I. Bekker (1846), containing Greek text only, and Beets (1900). There are monographs on special portions, by F. Rohde (on the theatrical terms, 1870), and F. von Stojatin (on constitutional antiquities, 1875).

POLLUX or **POLLUCITE**, a rare mineral, consisting of hydrous caesium and aluminum silicate, $H_2CsAl_2(SiO_3)_2$, and being the richest source of caesium, in demand for the construction of thermionic valves. Caesium oxide (Cs_2O) is present to the extent of 30%-36%, the amount varying somewhat owing to partial replacement by other alkalis, chiefly sodium. It crystallizes in the cubic system, it is colourless and transparent, and has a vitreous lustre. There is no distinct cleavage, and the fracture is conchoidal, so that the mineral closely resembles quartz in general appearance. The hardness is 6½ and the specific gravity 2.90. It occurs sparingly, together with the mineral "castor" (see PETALITE), in cavities in the granite of Elba, and with beryl in pegmatite veins at Andover and Hebron in Maine. (L. J. S.)

POLO, MARCO (c. 1254-1324), Venetian traveller, was grandson of Andrea Polo of San Felice, and son of Nicolo Polo. The three Polos were presumably "noble," for Marco the traveller is officially so styled (*nobilis vir*). The three sons of Andrea Polo were engaged in commerce, the eldest suggests, by his will, a long business partnership with Nicolo and Maffeo.

About 1260, Nicolo with his wife and Maffeo went to Constantinople. The two brothers were led in their trading operations to the Crimea, and eventually to Bukhara, where they joined some envoys returning from a mission from Kublai Khan, with whom they journeyed to Cathay. (See CHINA.) It was the first time that the khan had met Europeans and he was delighted with the Venetian brothers, whom he sent back to the pope, with letters requesting the despatch of a body of educated men to instruct his people in Christianity and the liberal arts. On arriving at Acre in April 1269, they learned that no new pope had been appointed after Clement IV's death in 1268, and they returned to Venice. The brothers resolved after two years to start again for the east, taking with them Nicolo's son, Marco. They had letters authenticating their delay, but, hearing of the papal election soon after their start, they returned to execute Kublai's mission. The new pope, however, could supply but two Dominicans, who soon turned back.

Leaving Acre about Nov. 1271, Polo's book indicates that the party proceeded to Hormuz (Hurmuz) at the mouth of the Persian gulf, with the purpose of going on to China by sea, but that, abandoning their plans, they returned northward through Persia. Traversing Kerman and Khurasan, they went on to Balkh and Badakshan and ascended the upper Oxus through Wakhan to the plateau of Pamir (a name first heard in Marco's book). Crossing the Pamir, the travellers descended upon Kashgar, Yarkand and Khotan (Khotan). These are regions which remained almost absolutely closed to western knowledge till after 1860. From Khotan they passed on to the vicinity of Lop-Nor. Thence the desert of Gobi was crossed to Tangut, the region at the extreme northwest of China, within and without the Wall. In his account of the Gobi, or desert of Lop, as he calls it, Polo describes the waste, strikingly reproducing the description of the superstitious terrors of Suan T'sang, who crossed the desert 600 years earlier.

Early in 1275 the Venetians were cordially received by the Great Khan at Shangtu, and Marco made rapid progress. The "young bachelor" studied the languages of the Khan's subjects and soon entered the public service. On his public missions he travelled through Shansi, Shensi, and Szechuen provinces, and the wild country on the borders of Tibet, to the province of Yunnan, called by the Mongols *Karajang*, and northern Burma (Mien). Marco,

during his stay at court, had observed the khan's interest in strange countries, and his disgust at the stupidity of envoys and commissioners who could tell of nothing but their official business. He made notes on facts likely to interest Kublai, which, on his return, he related. He encountered many semi-civilized and barbarous tribes, many of which interested Kublai greatly.

Marco rose rapidly in favour and was often employed on distant missions as well as in domestic administration, he held for three years the government of Yangchow, on another occasion he visited Kanchow, the capital of Tangut, just within the Great Wall, and perhaps Karakorum on the north of the Gobi, the former residence of the Great Khans also Ciampa, or southern Cochinchina, and perhaps, once more, on a separate mission to the southern states of India. We are not informed whether his father and uncle shared in such employments, though they rendered great service to the khan, in forwarding the capture of Siang-yang (on the Han river) during the war against southern China, by the construction of powerful artillery engines—a story, however, perplexed by chronological difficulties.

The Polos had become rich, and after their exile they began to dread what might follow Kublai's death. The khan, however, was deaf to suggestions of departure and the opportunity only came by chance. Arghun, khan of Persia, a grand-nephew of Kublai, lost in 1286 his favourite wife. Her dying injunction was that her place should be filled only by a lady of her own Mongol tribe. Ambassadors were despatched to the court of Peking to obtain one. The lady Coracin (Kukachin), a maiden of seventeen, was chosen. The overland road from Peking to Tabriz was then impeded by war, and Arghun's envoys proposed to return by sea. Having met the Venetians, and being eager to profit by their experience, they begged the khan to send the Franks in their company. He fitted out the party nobly for the voyage, sending friendly messages to the potentates of Christendom, including the pope, and the kings of France, Spain and England. They sailed from Zaiton or Amoy harbour in Fukien (probably the modern Changchow), then one of the chief Chinese havens for foreign trade, in 1292. The voyage involved long detention on the coast of Sumatra, and in south India, and two years or more passed before they arrived in Persia. Two of the three envoys and most of their suite died by the way, but the three Venetians survived all perils, and so did the young lady, who had come to look on them with filial regard. Arghun Khan had died before they left China, his brother reigned in his stead; and his son Ghazan married the lady. The Polos went on by Tabriz, Trebizond, Constantinople and Negropont to Venice, arriving about the end of 1295.

The first biographer of Marco Polo was John Baptist Ramusio, who wrote more than two centuries after the traveller's death. We need not hesitate to accept as a genuine tradition the substance of his story of the Polos' arrival at their family mansion in St. John Chrysostom parish in worn and outlandish garb, of the scornful denial of their identity, and the stratagem by which they secured acknowledgment from Venetian society.

We next hear of Marco Polo in a militant capacity. Jealousies had been growing between Venice and Genoa throughout the 13th century. In 1298 the Genoese prepared to strike at their rivals on their own ground, and a powerful fleet under Lamba Doria made for the Adriatic. Venice equipped a larger fleet under Andrea Dandolo. The crew of a Venetian galley at this time amounted to 250 men, under a *comuto* or master. On one of the galleys of Dandolo's fleet Marco Polo served as *sopracomito* or gentleman commander. The hostile fleets met before Curzola Island on Sept. 6 and engaged next morning. The battle ended in victory for Genoa, and Marco Polo was taken there as a prisoner. The captivity lasted less than a year, and Marco returned to Venice in July or August 1299.

His captivity was the immediate cause of his *Book*. Up to this time he had related his experiences among his friends, and from these stories he had acquired the nickname of *Marco Milioni*. Yet he had written nothing. The narratives not only of Marco Polo but of other famous mediæval travellers seem to have been extorted from them by pressure, and written down by other

hands. In the prison of Genoa Marco Polo met Rusticiano or Rusticello of Pisa, also a captive of the Genoese, who was a respectable literary hack; he wrote down Marco's experiences at his dictation.

We learn little of Marco Polo's history after this captivity, at his death he left a wife, Donata, and three daughters, Fantina, Bellella and Moreta. One last glimpse of the traveller is gathered from his will. On Jan. 9, 1324, he sent for a priest and notary to make his testament, and died the same day. He was buried, according to his wish, in the Church of St. Lorenzo. The archives of Venice have yielded a few traces of our traveller. Besides his own will just alluded to, there are the wills of his uncles, Marco and Maffeo; a few legal documents connected with the house property in St. John Chrysostom, and two or three entries in the record of the *Maggior Consiglio*. We have mentioned the sobriquet of Marco Milioni. Ramusio tells us that he had himself noted the use of this name in the public books of the commonwealth, and this statement has been verified in an entry in the books of the great council (dated April 10, 1305), which records as one of the securities in a certain case the "Nobilis vir Marchus Paulus Milon." It is alleged that long after the traveller's death there was always in the Venetian masques one individual who assumed the character of Marco Milioni, and told Munchausen-like stories to divert the vulgar. There is also a record (March 9, 1311) of the judgment of the court of requests (*Curia Petitionum*) upon a suit brought by the "Nobilis vir Marcus Polo" against Paulo Girardo, who had been an agent of his. Another document is a catalogue of curiosities and valuables in the house of Marino Faliero, which mentions several objects that Marco Polo had given to one of the Faliero family. The most tangible record of Polo's memory in Venice is a portion of the Ca' Polo—the mansion where the three travellers, after their long absence, were denied entrance. The court in which it stands was known in Ramusio's time as the *Corte del milione*, and now is called Corte Sabbionera. That which remains of the ancient edifice is a passage with a decorated 13th century archway.

No genuine portrait of Marco Polo exists. There is a medallion portrait dated 1761 on the wall of the Sala dello Scudo in the ducal palace. The oldest professed portrait is one in the gallery of Monsignor Badia at Rome, which is inscribed *Marcus Polus venetus totius orbis et Indis peregrator primus*. It is a good picture, but of the 16th century. The Europeans at Canton have absurdly attached the name of Marco Polo to a figure in a Buddhist temple there containing a gallery of "Arhans" or Buddhist saints, and popularly known as the "temple of the five hundred gods." The Venetian municipality obtained a copy of this on the occasion of the geographical congress at Venice in 1881.

Polo was the first traveller to trace a route across the whole longitude of Asia, describing kingdoms which he had seen, the first to speak of the court at Peking, the first to reveal China in its wealth and vastness, and to tell of the nations on its borders, the first to tell more of Tibet than its name, to speak of Burma, Laos, Siam, Cochinchina, Japan, Java, Sumatra, the Nicobar and Andaman Islands, Ceylon, India, but as a country seen and partially explored, the first in mediæval times to give any distinct account of the empire of Abyssinia, and of the island of Sokotra, and to mention Zanzibar and Madagascar, while he carries us also to the remotely opposite region of Siberia and the Arctic shores, to speak of dog sledges, white bears and reindeer-riding Tunguses.

Within the traveller's own lifetime, we find the earliest examples of the practical and truly scientific coast charts (*Portolans*), based upon the experience of pilots, mariners, merchants, etc. In two of the most famous of the 14th century Portolans, we trace Marco Polo's influence—in the *Lowrentian* or *Medicean Portolano* of 1351 (at Florence), and in the *Catalan Atlas* of 1375 (now at Paris). Both represent a very advanced stage of mediæval knowledge, a careful attempt to represent the known world on the basis of collected fact, and a disregard for theological or pseudo-scientific theory; in the *Catalan Atlas*, as regards central and further Asia, and partially as regards India, Marco Polo's book is the basis of the map. His names are often much perverted, and it is not always easy to understand the view that

the compiler took of his itineraries. Still we have Cathay placed in the true position of China, as a great empire filling the south-east of Asia. The trans-Gangetic peninsula is absent, but India proper is for the first time represented with a fair approximation to correct form and position. The map of Fra Mauro (1459) gives a much less accurate idea of Asia than the *Carta catalana*. Columbus possessed a copy of the Latin version of Polo's book made by Pipino, and on many pages of this there are manuscript notes in the admiral's handwriting, testifying to the influence of the work of the Venetian merchant upon the discoverer of the new world.

When, in the 16th century, attempts were made to combine new and old knowledge, the results were unhappy. The earliest of such combinations tried to realize Columbus' ideas regarding the identity of his discoveries with the great khan's dominions, but even after America had vindicated its independent existence, and the new knowledge of the Portuguese had named China where the Catalan map had spoken of Cathay, the latter country, with the whole of Polo's nomenclature, was shunted to the north, forming a separate system. Henceforward the influence of Polo's work on maps was simply injurious, and when to his names was added a sprinkling of Ptolemy's, as was usual throughout the 16th century, the result was a hotchpotch conveying no approximation to facts.

As to the alleged introduction of important inventions into Europe by Polo—although the striking resemblance of early European block books to those of China seem clearly to indicate the derivation of the art from that country, there is no reason for connecting this introduction (any more than that of gunpowder or the mariner's compass) with the name of Marco. In the 14th century not only were missions of the Roman church established in eastern China, but a regular overland trade was carried on between Italy and China. Many a traveller other than Marco Polo might have brought home the block books, and some might have witnessed the process of making them. This is the less to be ascribed to Polo, because he so curiously omits to speak of the process of printing, when, in describing the block-printed paper money of China, his subject seems absolutely to challenge a description of the art.

The book indited by Rusticano is in two parts. The first, or prologue, as it is termed, is unfortunately the only part which consists of actual personal narrative. It relates the circumstances which led the two elder Polos to the khan's court, together with those of their second journey (when accompanied by Marco), and of the return to the west by the Indian seas and Persia. The second part consists of a series of chapters of unequal length and unsystematic structure, descriptive of the different states and provinces of Asia (certain African islands and regions included), with occasional notices of their sights and products, of curious manners and remarkable events, and especially regarding the Emperor Kublai, his court, wars and administration. A series of chapters near the close treats of sundry wars that took place between various branches of the house of Jenghiz in the latter half of the 13th century. There is now no doubt that the original was written in French. A manuscript in rude and peculiar French, belonging to the National Library of Paris (Fonds, Fr., 1176), which was printed by the Société de géographie in 1824, is evidently either the original or a close transcript. It shows characteristics of the unrevised product of dictation which would necessarily have disappeared in a translation or revised copy. Eighty-five mss of the book are known, and their texts exhibit considerable differences. For a discussion of these see the authorities quoted in the bibliography.

We know from Gilles Mallet's catalogue of the books collected in the Louvre by Charles V, dating c. 1370-75, that five copies of Marco Polo's work were then in the collection; but on the other hand, the 202 known mss and the numerous early printed editions of "Mandeville," with his lying wonders, indicate a much greater popularity. Dante, who lived 23 years after the book was dictated, never alludes to Polo; nor can any trace of Polo be discovered in the book of his contemporary, Marino Sanudo the Elder, though he is well acquainted with the work of Hayton the Armenian. Mandeville himself, who plundered right and left,

hardly ever plunders Polo. The only literary works we know of the 14th century which show acquaintance with Polo's book or achievements are Papino's *Chronicle*, Villani's *Florentine History*, Pietro d'Abano's *Consiliator*, the *Chronicle* of John of Ypres, and the poetical romance of *Baudouin de Sebourg*.

BIBLIOGRAPHY.—The *Recueil* of the Paris Geographical Society (1824), vol. 1, giving the text of the fundamental mss (Nat. Lib. Paris, Fr., 1176, see above), as well as that of the oldest Latin version, G. Pauthier's edition, *Le livre de Marco Polo*. (Paris, 1865), based mainly upon the three Paris mss (Nat. Lib. Fr., 2810, Fr. 5631, Fr. 5649, see above) and accompanied by a commentary of great value, Baldelli-Boni's Italian edition, giving the oldest Italian version (Florence, 1827), Sir Henry Yule's edition, which in its final shape, as revised and augmented by Henri Cordier (London, 1903), is the most complete storehouse of Polo learning in existence, embodying the labours of all the best students of the subject, and giving the essence of such works as those of Major P. Meadows Sykes (*Ten Thousand Miles in Persia*, etc.) so far as these touch Marco Polo; the Archimandrite Palladius Katherov's "Elucidations of Marco Polo" from vol. x of the *Journal* of the North China branch of the Royal Asiatic Society (1876), pp. 1-54, F. von Richthofen, *Letters to Shanghai Chamber of Commerce*; E. C. Baber, *Travels*. In *Western China*, G. Phillips, *Identity of Zastun with Chongshu in Tsung Pao* (Oct. 1890), and other studies in *Tsung Pao* (Dec. 1895 and July 1896). There are in all 10 French editions of Polo as well as 4 Latin editions, 27 Italian, 9 German, 4 Spanish, 1 Portuguese, 12 English, 2 Russian, 1 Dutch, 1 Bohemian (Czech), 1 Danish and 1 Swedish. Raymond Beazley, *Down of Modern Geography*, m, 15-160, 545-547, 554, 556-563; R. Allul, *Marco Polo* (1903). (H. V. X.)

POLO, the most ancient of games with stick and ball. Its name is derived from the Tibetan *pu*, a ball. Hockey, the Irish national game of hurling, and possibly golf and cricket, are derived from polo. The latter was called hockey or hurling on horseback in England and Ireland respectively, but historically hockey and hurling are polo on foot. The earliest records of polo are Persian. From Persia it spread to Constantinople eastwards through Turkistan to Tibet, China and Japan. From Tibet polo travelled to Gilgit and Chitral, possibly also to Manipur. Polo also flourished in India in the 16th century. Then for 200 years its records in India cease, till in 1863 polo came into Bengal from Manipur by way of Cachar.

Chronology of Modern Polo.—Polo was first introduced to India in 1863 by Maj. Gen. Sherar. He brought two teams of Manipuri natives from Manipur to Calcutta, where they played an exhibition match. In 1869 polo was brought to England by the 10th Hussars. In 1871 the first recorded match took place on Hounslow Heath between the 9th Lancers and the 10th Hussars with eight players on each side. An account of this match appeared in the *Morning Post* in July 1871. In 1873 the numbers on each side were reduced to five. A match under these conditions took place at Lillie Bridge. The first code of rules was drawn up by the committee of the Hurlingham club in 1874. In 1876 the height of ponies was fixed by Hurlingham at 14 o hands and the Champion cup was inaugurated at Hurlingham with five players on each side. In 1877 the first inter-regimental tournament was held in India, and in 1878 at Hurlingham. In the same year the first county cup tournament and the first Oxford v Cambridge match were held at Hurlingham, and the first All-Ireland open cup at Phoenix park, Dublin. In 1882 the number of players on each side was reduced to four. In 1884 John Watson introduced the back-hand stroke to Hurlingham from India, and placed the players at No. 1, No. 2, No. 3 and No. 4 or back, thus laying the foundation of the modern combination game. In 1886 John Watson took the first team to the U.S. and won the Westchester cup.

Watson taught the U.S. players the back-hand stroke and the rudiments of the combination game. In 1888 the height of ponies in India was raised from 13.2 to 13.3. In 1895 the height of the ponies was raised by the Hurlingham committee to 14.2 and an official measurer appointed. In 1902 a U.S. team first visited England and was defeated by England by two matches to one. In India the height of ponies was raised to 14.1. In 1909 the U.S. won the cup at Hurlingham. In 1910 handicapping was introduced

into English polo, and offside was abolished. Both these innovations were copied from the U.S. India adopted these alterations. In 1911 and 1913 England was defeated in the U.S. In 1914 England beat the U.S. team in the U.S., and brought the cup back. In 1919 the height limit for ponies was abolished. In 1921 the U.S. regained the cup from England. In the same year a committee sat in London during the summer and evolved a code of universal rules. This code of rules has been adopted wherever polo is played, with local modifications as regards height of ponies and the duration of matches. In 1924, 1927, 1930, 1936 and 1939 England was defeated by the U.S.

The Game.—A full-sized ground should not exceed 300 yd. in length by 200 yd. in width, if unboarded and 300 yd. in length by 160 yd. in width, if boarded. The goals are not less than 250 yd. apart, and each goal 8 yd. wide.

Polo is played with four players on each side, on exactly the same principles as hockey or association football. A match lasts about one hour, divided into periods of play, during the intervals ponies are changed. In England seven periods of eight minutes are played for a full match, in the U.S., eight or six periods of seven-and-a-half minutes. The players are placed at No. 1, No. 2, No. 3 and No. 4 or back, so there are two forwards and two backs. But during the course of the game as the players pass the ball to one another these places are being constantly changed. The modern game is a most elastic one, but there should always be one player in each place.

Two umpires are required in a first-class match to award the penalties for infringement of the rules, and in an important tournament a referee at the side of the ground decides disputes if the umpires disagree.

The Development of the Method of Play.—Previous to John Watson's teaching, the method of play was for one man on each side to be the goalkeeper, and for the others to play forward and to hit the ball when and how they could. He introduced the back-hand stroke, and placed his men at No. 1, No. 2, half-back or No. 3, and back. He also taught them to combine and hit to each other. But he taught the game on rather wooden and inelastic lines. Then the brothers Peat appeared on the scene, and soon found out and demonstrated how to play the game in a more scientific manner and with such success that they won the champion cup at Hurlingham on eight occasions. Then came the era of the Freebooters', Rugby, Old Cantab and Roehampton teams, and of the various good regimental teams, such as the 7th, 10th, 11th, 13th and 20th Hussars, the 9th and 17th Lancers and the Inniskilling Dragoons. The training both of men and ponies was rapidly improved. A very scientific game was developed, accurate combination being carefully taught, but too much importance was probably directed to defense, the principles of attack not being sufficiently developed.

While this was going on in England, polo was being rapidly improved in India, and many very fine players were produced there. The ponies were then much smaller, and consequently much more easy to train and ride. The grounds were harder and much easier to hit the ball on, also as the game was played in India all the year round, far more practice was possible. Everything seemed to be in a satisfactory state as regards the game till 1909, when English polo players got a rude awakening from the U.S. team at Hurlingham, who defeated the English representatives very easily.

The U.S. had never adopted the offside rule. They consequently developed a very much faster game. They also perfected strokes that had hardly been attempted elsewhere. They met the ball on all possible occasions and hit under their ponies' necks instead of hitting back-handers from the side of the ground. They played a most elastic game, hitting harder and passing more accurately. They had developed the science of the attack, galloped faster, and were much more accurate goal hitters.

In 1909 the Hurlingham club decided to profit by the lessons learned from the U.S. in 1909, and made two most important alterations in their rules. Offside was abolished and handicapping was introduced. The abolition of offside quickened up the game to a very great extent, and the institution of handicapping re-

sulted in much harder and more even matches. The periods of play were shortened from ten to eight minutes, seven periods being played for a match instead of six. English polo probably reached its zenith in 1914 when the English team which visited the U.S. brought the cup back.

The Hurlingham club rules and the general and field rules of the U.S.A. Polo association are now practically identical, and except for minor differences, such as height of ponies and the duration of matches and periods of play, the Hurlingham rules are followed all over the world.

The Effects of the World Wars.—World War I gave a serious setback to English polo. The expenses of polo increased vastly over prewar years. In 1919, owing to the pony wastage of the war, the troubles in Ireland, formerly the chief source of supply of high-class ponies, and the fact that the breeding of ponies in both England and Ireland had almost ceased, it was impossible to supply the demand for 143 ponies of the right stamp. This necessitated the abolition of the height limit. The big thoroughbred pony thereafter used in first-class polo was more expensive to buy, dearer to keep and much more difficult to train and to ride. Also, undoubtedly, the abolition of offside and the institution of handicapping made the game more expensive. For the handy pony of moderate speed became quite useless for an ordinary good game, and the handicap entailed far more close matches, which meant that more ponies were required. In spite of this polo was in a very flourishing condition until the outbreak of World War II. In Great Britain it was played at Hurlingham, Ranelagh, Roehampton, and at about 30 county clubs affiliated with the County Polo association. It was played throughout the British empire, wherever sufficient players could collect together to make up a game. It was played all over India, many of the maharajahs and chiefs kept up teams in the native states. It was played on the continent, and was fast becoming a national game in the U.S.A. The game became practically dormant during World War II.

Polo Centres and Tournaments.—Prior to World War II, London attracted most of the best players of the world. During the season, May 1 to July 31, matches and tournaments for every class of player were held at Hurlingham, Ranelagh and Roehampton. These clubs maintained seven grounds, as well as three at Worcester park as an overflow. First-class teams from the U.S., India and the Argentine took part in the various tournaments, and as a rule there were two or three first-class English teams competing in all the principal events such as the Whitney Cup, the Champion Cup, the Ranelagh Open Cup and the Roehampton Open Cup. The second- and third-class players were catered for equally well in a variety of lesser competitions; the soldiers had their own tournaments, i.e., the inter-regimental at Hurlingham, the Subalterns' Cup at Ranelagh and the handicap military tournament at Roehampton. The whole organization was well-nigh perfect, controlled by professional polo managers. India had good tournaments at far separated places such as Calcutta, Delhi, Meerut, Amballa, Rawalpindi, etc., but there was no place in India where good polo could be concentrated for a lengthy period as in England. In England a good player could play at Minehead, Somerset, in April, he could then go to London for May, June and July, then came the county tournaments beginning at Cowdray in Goodwood week, Rugby in the first week in August, Cirencester, Cheltenham, Tidworth, and he could finish up with a month of good games at Minehead. A keen player could, weather permitting, get nearly six months on end of match play.

Breeding of Polo Ponies.—The interest of the breeding of polo ponies is supervised by the National Pony Society. This society edits a stud book for all kinds of riding ponies, and holds an annual show at the Agricultural Hall, Islington. The society gives prizes and medals at many shows for polo pony classes. It has done, and is still doing, a great work for the encouragement of the breeding of the best class of riding pony.

Up to the year 1909 nearly all the best polo ponies used in the game were bred in Ireland, England and Australia. The latter were chiefly used in India. In India, until about 1883, country-breeds were relied on chiefly, very good animals, not more than 13.5 in

TECHNIQUE AND PLAYS IN POLO

1. A thong attached to the haft of the mallet is wound tightly around the player's wrist to insure against loss of the mallet during play. The ball is hit with the side, not the head, of the mallet.
2. Proper arrangement of the bridle reins on a polo pony. A martingale passed between the pony's forelegs and fastened to the girth under the belly gives the rider added control over his mount.
3. Player making a backhand save. The ball is at the far right.
4. Strobe flash photograph of beginning of the swing in a backhand save.
5. The player at the left is racing forward to receive a pass from his teammate (right) who is being pressed from behind by an opponent.
6. Making a goal.

height. Then Arabs began to be bred in greater numbers, only to be superseded in their turn by wallahs from Persia, which were imported in large numbers by dealers in Cavendish and Bombay. When the height was raised to 14 ft. in 1902, only the very best Arabs and a few country-breds produced on the government and regimental farms could compete with the Australian pony in high-class tournaments. Large numbers of easy, handy rather common ponies were imported from 1892 to about 1909 from the Argentine to England. They were cheap and easy to play, but as a rule rather deficient in pace. Occasionally an absolutely first-class pony appeared, but they were few and far between. But since 1909 the class of pony bred in the Argentine has improved, out of all recognition. Several generations of thoroughbred stallions have been used to such an extent that as good ponies as can be obtained anywhere are produced and exported. Many quite thoroughbred ponies are bred in the Argentine, and the remainder of the best animals have only a far back strain of the native pony in their pedigree on the dam's side. The best ponies, however, their nationality, thoroughbred or very nearly so. Probably the ideal breeding is for the sire to be thoroughbred and the dam nearly if not quite thoroughbred of the hardy old Irish stock. The National Pony Society in England, and the polo breeding societies in the U.S. and the Argentine are doing a great work in proving that polo ponies can be bred to type.

BIBLIOGRAPHY—Accounts of the origin of forms of polo were found in the following works: Persia: *Indo-Iranian Shahnama*, A. Shukry, *Travels in Persia* (1866), J. Chardin, *Voyages en Perse* (1807), W. Ouseley, *Travels in various countries of the East, particularly Persia* (1807). There are many allusions to polo in the poets, notably Nizami, Jami and Omar Kha-yam. Constantinople: *Cinquantième Joannes ephemerum ab Iovine et Alex. Cennusius gest.* (Bonn, 1835). India: *Ami Akbari* (1853), G. F. Vigne, *Travels in Kachhar, Ladakh and Iskardo* (1842), A. Durnell, *The Making of a Frontier* (1899), Gillet and Chitral, "Polo in Balistan," *The Field* (1888), Manjur W. McCulloch, *Account of the valley of Monapure and the Hill Tribes* (Calcutta, 1899). China and Japan: H. A. Giles, *Adventurous Sinner* (Shanghai, 1905), B. H. Chamberlain, *Things Japanese* (1898), the *Ku Chin Tu Shu* (Encyclopaedia).

For the modern form of the game see J. Moray Brown, *Riding and Polo*, Badminton Library (revised by T. T. Dole, 1930), and P. (1896), G. I. Youngblood, *Polo in India*, (1907), *Tournament Polo* (1897), *Tournament Polo* (1904), T. F. Little, *The Game of Polo* (1897), H. de B. de Lisle, *Hints to Polo Players in India* (1897), T. B. Dryburgh, *Polo* (1898 revised 1906), E. D. Miller, *Modern Polo* (1903), H. E. Fitzpatrick, *Equine Polo*, in *Spalding's Athletic Library* (1904), W. Buckmaster, "Hints on Polo Contention," *Library of Sport* (1909), W. C. Farley, *Is to Polo* (1920), W. B. Devere, *Position and Team Play in Polo* (1924), Hurlingham Club, *Rules of Polo*, *Register of Ponies, Polo and Riding Pony Society Stud book* (12 volumes), *Periodicals*: *Baileys Magazine*, *The Polo Monthly*, *The American Polo Association* and the *Indian Polo Association* issue annual publications. (E. D. M., X.)

United States—Attack was always stressed in play in the U.S. The system of fractional fouls also aided speed. Instead of stopping the game on a foul, and allowing a free hit from varying distances for the goal, a fraction was deducted from the offending side's score and play continued without a break. In 1888 what has since been regarded as perhaps the most important legislative contribution to the sport came with the first handicapping of players. The game, until that time, had been pretty well monopolized by the better players and H. L. Herbert conceived the idea of the handicap to make possible a wider spread of play. The handicap, low at the start of a player's career, increases with his ability. Thus the beginners are able to play with the more experienced players on a far more even footing. Only the international matches and the open tournaments are played without handicap. In a game the handicaps of all four players are totalled and the team handicaps compared.

One team (unless the totals are even) then receives the difference in total handicap. The handicapping system almost immediately resulted in new tournaments and new clubs, among them Myopia and the Dedham Polo and Country Club, two of the most famous of the Boston district.

Ten goals was the highest rating ever given to a player. This was held in the U.S. game at varying times by the following: Foxhall P. Keene, John E. Cowdin, Thomas Fitzcheck, R. L. Agassiz, J. M. Waterbury, Jr., Lawrence Waterbury, Harry P.

Whitney, Louis E. Stoddard, J. Walton Webb, M. Stevenson, D. Milburn, Thomas Fitzcheck, Jr., Cecil Smith, Elmer Boescke and Stewart Jglehr.

After the U.S. won its first victory in the international series with England the rules were assimilated. The U.S. took over the British rule pertaining the hooking of mallets, and the English abandoned their offside rules and adopted the handicap system. At the close of World War I in 1918 all effort at limiting the size of ponies was abandoned.

At first the U.S. teams played with native horses, mainly found in the southwest and descended in part from the Spanish barb left by those who penetrated that part of the United States in its early history. Later, though Texas and Wyoming produced a great many polo horses, the thoroughbred was much in demand, with English and Irish blood prominent in a certain line of mounts. The ponies of Argentina became perhaps the most popular among the higher-rated players. (R. F. K.)

POLOCK, MOSES (1817-1903), U.S. publisher and bibliophile, was born in Philadelphia, Pa., on May 14, 1817, of Jewish-Dutch parentage. At 14 he was apprenticed to the firm of McCarty and Davis, then an old and established Philadelphia house of bookdealers and publishers. He became their chief businessman and succeeded to ownership of the firm in 1853. Pollock is chiefly remembered as the first rare bookdealer to devote himself solely to Americana. At that period many of the most distinguished U.S. libraries were being formed, including the collections of James Lenox (which became part of the N.Y. public library) and S. W. Pennypacker, and Pollock's knowledge and experience as a bibliographer were highly valued. Notable among his own publications was the first collected edition of the works of Charles Brockden Brown (1791), earlier of U.S. novelists, which appeared in 1857. He was also responsible for the first U.S. collection of children's literature. William Bathrood, a contemporary bookdealer in Philadelphia, has described him as a reticent and learned man who gradually lost interest in selling his books in his growing absorption as a collector (*Forty Years among the Old Booksellers of Philadelphia*, 1891). Pollock died on Aug. 16, 1903.

POLONAISE, a stately ceremonial dance, usually written in three-fourths time. As a term of musical composition it has been employed by such composers as Bach, Handel, Beethoven and above all by Chopin. It is usual to date the origin of the dance from the election (1573) of Henry, duke of Anjou, afterward Henry III of France, to the throne of Poland. The ladies of the Polish nobility passed in ceremonial procession before him at "cracow" to the sound of stately music. This procession to music became the regular opening ceremony at royal functions and developed into the dance.

The term is also given to a form of skirted bodice, which has been fashionable for ladies at different periods.

POLONIUM (see also RADIOACTIVITY, NATURAL). A radioactive element, symbol Po, atomic number 84.

Historical—This element was discovered in 1898 by Pierre and Marie Curie. Having found that the radioactivity of uranium and thorium minerals was much greater than could be predicted by the content of uranium and thorium, they undertook to extract the substance responsible for this anomaly from a uranium mineral, Joachimsthal pitchblende. Since the only known property of this hypothetical substance was its radioactivity, Pierre and Marie Curie developed a new experimental method which has remained the basis of all radioactive chemistry. They carried out separations of the various substances in the mineral and measured the radioactivity of each portion. They quickly found that the activity became concentrated, partly with the alkaline earths and partly with the sulphides precipitated from acid solution. They were soon able to confirm the existence of two new radioelements: one a higher homologue of barium—radium; the other a homologue of tellurium, to which they gave the name polonium in honour of Marie Curie's birthplace, Poland. It was the first element to be discovered by the radiochemical method.

Since then the term polonium has been used in a more general sense and fills the 84th place in Dmitri Mendeleev's table, allotted to the numerous isotopes listed below. Some of these iso-

topes are members of the natural radioactive families (Their individual symbols are given in parenthesis) The others are artificial radioelements

Isotope	Period	Manner of Disintegration
Po^{212}	0 days	K (90%), α (10%)
Po^{214}	5 hr	K (about 100%), α (0.01%)
Po^{218}	about 3 yr	α
Po^{219}	very long (?)	α
Po^{210} (RaF)	140 days	α
Po^{211} (AcC')	5×10^{-4} sec	α
Po^{213} (ThC')	3×10^{-4} sec	α
Po^{215}	4.4×10^{-6} sec	α
Po^{216} (RaC'')	1×10^{-4} sec	α
Po^{217} (AcA)	1.8×10^{-5} sec	β (about $5 \times 10^{-6}\%$), α (about 100%)
Po^{218} (ThA)	0.158 sec	β (about 0.014%), α (about 100%)
Po^{219} (not discovered)		
Po^{218} (RaA)	3.05 min	β (0.04%), α (about 100%)

The radioelement discovered by Pierre and Marie Curie is the principal isotope Po^{210} .

Natural Occurrence and Preparation.—Polonium is found in much smaller amounts than radium in minerals containing uranium. About 2,900 kg of uranium element are in radioactive equilibrium with 1 g of radium and 0.224 mg of polonium (1 curie). It can therefore be estimated that the polonium content of a Joachimsthal pitchblende containing 65% of uranium is about 0.05 mg. in 1,000 kg. of the mineral.

The half life of polonium is long enough to enable it to be extracted directly from uranium minerals. This process has been used but is of little practical value. It is usually extracted either from radio-lead, which is a by-product of the extraction of radium from uranium minerals, or from radium D, obtained by washing old radium tubes which contain the long-lived active deposit radium D+E+F (I. Curie), or it can be extracted from old preparations of radium salts (E. Rona).

The extraction of polonium from solutions of radium D, as well as the preparation of strong sources (up to about one to two micro-curies/cm²) of this radioelement is usually carried out by electrochemical deposition on Ag or Ni from a weak solution of acetic, nitric or hydrochloric acid. On Ag, Po is deposited free from RaE and RaD; on Ni, from hot solution, Po and RaE are deposited almost free from RaD (W. Marckwald, I. Curie, O. Erbacher and K. Philipp).

Strong sources can be obtained by volatilizing polonium at red heat in a quartz tube in a current of nitrogen or argon and collecting it on a cooled metallic surface (E. Rona and E. Schmidt, I. Curie and F. Joliot).

Finally, element number 84 can be produced artificially by transmutation of atoms of lead or bismuth (J. J. Livingood, D. G. Hurst, R. Latham and W. B. Lewis; D. H. Templeton, J. J. Howland and I. Perlman).

In certain nuclear reactions it is formed directly:

In others, Bi^{213} (RaE) is formed immediately.

and Bi^{213} from Po^{210}

Properties and Radioactivity.—In 1920 Marie Curie and A. Debierne, using about 0.1 mg of Po mixed with a few milligrams of other metals, studied the spark spectrum of this material and observed several lines attributable to polonium, the most intense of which was at 4,170 Å. In 1930 A. Czapek pointed out the existence of a line at 2,450 Å. B. Karlik and H. Peterson confirmed this and have drawn attention to a line at 2,558 Å.

The coefficient of diffusion of polonium at ordinary temperature in Al, Fe, Ni, Cu, Ag, Au and Pb is low, about 10^{-14} cm²/day according to E. Rona and E. Schmidt. In gold and platinum at 470° it is about 10^{-8} cm²/day (L. Wertenstein and H. Dobrowolska).

According to P. Bonet-Maury, the rate of volatilization *in vacuo* of Po deposited on Ni is measurable at 108° C. and, on heating for 5 min at 350° C., 90% of the polonium atoms are liberated. From Pt, volatilization does not begin until about 350°.

According to Rona it begins from Au at a slightly lower temperature and from Pd only at about 500°–560° C. The vaporization temperature of Po increases with the age of the product. It also varies with the method of preparation of the sources and the gaseous atmosphere into which volatilization is carried out.

Since polonium belongs to the radioactive family uranium-radium and is formed by the disintegration of radium E, an isotope of bismuth, it is sometimes called radium F (RaF).

It disintegrates in its turn with the emission of α -rays to give radium G, an inactive isotope of lead (Pb^{206}). The disintegration period (half life) of polonium is 140 days.

Period = 1,590 3,82 3.05 26.8 19.7 1.57 $\times 10^{-4}$ 22 5 140 years days min min min sec min sec years days stable

The range of the α -rays from polonium has been determined with great accuracy by Irène Joliot-Curie and is 3.87 cm in air at 15° C and 760 mm of Hg. In the gelatin of usual photographic plates it is about 27 μ and in aluminum, 22 μ . During its passage through air each of the α -particles emitted gives rise to 152,000 pairs of ions. It is calculated that the amount of polonium corresponding to a saturation current of 1 E.S.U. in an ionization chamber utilizing all the ions produced in a solid angle of 2π is equal to 1.67×10^{-10} g. A current of 1,350 E.S.U. represents 1 millicro-curie. This α -radiation, which does not seem to be of uniform (kinetic) energy, is accompanied by γ -radiation of weak intensity (about one quantum of 0.773 Mev for 10⁶ α -particles) and a secondary β -radiation. According to A. Samelievsky the hourly heat output of 1 E.S.U. of polonium, equivalent to the kinetic energy of the α -rays and the recoil RaG atoms is equal to 20.24×10^{-10} cal.

M. Curie and A. Debierne have been able to make a direct determination of the Avogadro number by measuring the volume of helium corresponding to a known number of α -particles emitted by a source of polonium.

The radiation from polonium can bring about the decomposition of water; the decomposition of air, the marking of photographic plates and the coloration of glass or quartz. It exerts a toxic effect on living organisms. A rabbit injected with 500 E.S.U. of Po wasted considerably and died a few days afterward (A. Lacassagne, J. Lattès and J. Lavedan).

Polonium is often used in radioactivity as a source of α -radiation free from penetrating rays. I. Curie and F. Joliot discovered artificial radioactivity in 1934 by bombarding aluminum, boron and magnesium with α -rays from polonium. A deposit of polonium on beryllium forms a natural source of neutrons which are produced by the nuclear reaction:

and

The chemical and electrochemical properties of polonium were determined by radiochemical methods using very small amounts of the order of 10^{-11} to 10^{-12} g of Po^{210} (RaF).

Polonium in 1- to 5 normal solutions of nitric, hydrochloric or acetic acid is deposited spontaneously on Ag, Te, Bi, Ni and on the less noble metals (Marckwald and others).

By the action of an electric current it can be collected from acid solution on the cathode, probably in the metallic state, and on the anode as the peroxide (F. Paneth and G. Hevesy). Similarly, deposits on the cathode and the anode can be obtained from sufficiently alkaline soda solution (M. Haussinsky).

The critical deposition potential of Po in acid solution, for concentrations in the region of 10^{-4} to 10^{-10} normal, has been determined by the decomposition potential method devised by Hevesy and Paneth and considerably improved by F. Joliot. Assuming that Nernst's electrochemical law is applicable when extrapolating to normal potential, as shown by the experiments carried out by Haussinsky with solutions of Bi and its isotopes RaE and ThC, it is found for the electrode $\text{Po}/\text{Po}^{+++}$ with respect to the hydrogen electrode that

$$E_h^0(\text{Po}/\text{Po}^{+++}) = -0.77 \text{ v. at } 18^\circ \text{ C.}$$

Polonium is situated, then, between Ag and Te in the normal potential series.

F. Joliot has shown that the cathode deposition potential is lowered if electrolysis is carried out in acid solution in the presence of different reducing agents.

Chemical Properties.—Chemically, polonium being the higher homologue of tellurium and next to bismuth in the periodic table is allied to both these elements.

The following properties of polonium are in common with those of tellurium and bismuth: hydrolysis of its compounds in aqueous solution near the neutral point with the formation of an insoluble hydride, precipitation of a sulphide insoluble in dilute acid (P and M. Curie), reduction to the metallic state by hypophosphorus and hydrosulphuric acid, TiCl_4 in hydrochloric acid solution and by hydrazine and formaldehyde in soda solution (M. Guillot and Haissinsky).

Polonium resembles tellurium in its amphoteric character. It can, in effect, act as a cation in acid solution but also gives a volatile hydride PoH_2 (Paneth) and a sodium polonide NaPo (V. Khlopov and A. Samartseva). Polonium hydroxide ($\text{O}=\text{Po}=\text{OH}_2$) is equally amphoteric and dissolves in concentrated sodium hydroxide to give a polonate Na_2PoO_3 , analogous to the tellurates (J. Escher-Desvrières). As with tellurium, polonium is precipitated in the metallic state from hydrochloric acid solution by SnCl_2 (Marckwald). Finally, according to M. Guillot, it forms polonium hexachlorides isomorphous with similar salts of Te, Pb, Sn, Pt ($[\text{MIVCl}_6][\text{NH}_4]_2$) and is then, in that case, quadrivalent and hexa-co-ordinated.

On the other hand, contrary to tellurium, polonium is not precipitated from acid solution by hydrazine and SO_2 . It resembles bismuth in the insolubility of its sulphide in ammonium sulphide in alkaline solution (M. Curie) and the insolubility of its pyrolytate in weakly acid solution (Haissinsky). Furthermore, M. Guillot has obtained mixed crystals of dithiocarbamates of polonium and the trivalent metals Bi^{+++} and Co^{+++} . This worker explains the analogies between Po and Bi by supposing that certain reducing agents convert polonium to the trivalent state, which is in agreement with the existence of two cathode deposition potentials. The co-ordination index of the ion Po^{+++} in the complex should be the same as Po^{+++} and equal to 6. Under certain conditions it forms an oxychloride soluble in anhydrous ethyl alcohol, acetone and dioxane (G. Boussières).

An acetylacetonate of polonium is known (M. Servigne), also a polonium methyl (V. Khlopov and A. Samartseva) and a polonium carbonyl (I. Curie and M. Leconte).

Summarizing, chemical and electrochemical work has led to polonium's being attributed positive valencies 6, 4, 3 and negative valency 2.

Dosage.—A thin layer of polonium is prepared when measuring the ionization produced by its α -radiation. If it is mixed with other salts, it must be extracted by electrochemical deposition on silver or nickel foil ($1 \text{ ESU equals } 1.67 \times 10^{-10} \text{ g. of Po}$). The magnitude of the activity of a source can be readily judged by the luminosity produced in the dark on a screen of zinc sulphide placed in front of it.

Glossary of Technical Symbols Used in This Article

Ra	Radium	Te	Tellurium
Ac	Actinium	Bi	Bismuth
Th	Thorium	Pb	Lead
Ag	Silver	Sn	Tin
Ni	Nickel	Co	Cobalt
Pt	Platinum	TiCl_3	Titanous chloride
Al	Aluminum	SnCl_2	Stannous chloride
Fe	Iron	μ	Sulphur dioxide
Cu	Copper	μ	Micron ($=10^{-3} \text{ mm}$)
Pd	Palladium	e.s.u.	Electrostatic unit
Hg	Mercury	MeV	Million electron volts

(I. J.-C., G. Bs)

POLONNARUWA, a ruined city and ancient capital of Ceylon. It first became a royal residence in A.D. 368, when the lake of Topawewa was formed, and succeeded Anuradhapura as the capital in the middle of the 8th century. The principal ruins date chiefly from the time of Prakrama Bahu (A.D. 1153–86). The most imposing pile remaining is the Jetavanarama temple, a building 170 ft in length, with walls about 80 ft high and 12 ft thick. The city is now entirely deserted, and, as in the case of Anuradhapura, its ruins have only recently been rescued from the jungle.

POLOTSK, a town of the white Russian S.S.R., at the confluence of the Polota and Dvina, in $55^\circ 29' \text{ N}$, $28^\circ 49' \text{ E}$. Pop (1933) 25,300. It is on a railway junction and has sawmilling and timber industries and a flour mill. Its position between central Russia and the west made it a storm centre, and little of the ancient town remains, both the upper castle, which had seven towers, and the lower one are in ruins and its 12th-century cathedral fell in ruins in the 18th century.

Polotsek or Poltesk is mentioned in 862 as one of the towns

given by the Scandinavian Rurik to his men. In 980 it had a prince of its own, Ragvald (Rogvolod or Rognvald), whose daughter is the subject of many legends. It remained an independent principality until the 12th century, resisting the repeated attacks of the princes of Kiev, those of Pskov, Lithuania, and the Livonian knights, however, proved more effective, and Polotsk fell under Lithuanian rule in 1320. About 1385 its independence was destroyed by the Lithuanian prince Vitovt. It was five times besieged by Moscow in 1500–18 and was taken by Ivan the Terrible in 1563. Recaptured by Stephen Bathory, king of Poland, 16 years later, it became Polish by the treaty of 1582. It was then a large and populous city and carried on an active commerce. Pestilences and conflagrations were its ruin, the plague of 1566 wrought great havoc among its inhabitants, and that of 1600 destroyed 15,000. The castles, the town and its walls were burned in 1607 and 1642. The Russians continued their attacks, burning and plundering the town, and twice, in 1633 and 1705, taking possession of it for a few years. It was not definitely annexed to Russia until 1772, after the first dismemberment of Poland. In 1812 its inhabitants resisted the French invasion, and the town was partially destroyed.

POLTAVA, a town in the Ukrainian S.S.R., Union of Soviet Socialist Republics, on the right bank of the Vorskla river, in $49^\circ 36' \text{ N}$, $34^\circ 35' \text{ E}$. Pop (1939) 130,305.

It is the centre of an agricultural district in which grains, sugar beets, tobacco, vines and orchard fruits are grown. Leather is the chief manufacture, and there is an annual fair for the sale of skins, leather and leather goods. Other industries include smelting, stocking manufacture, distilling and brewing. The town is on the railway and is a grain-collecting centre. The Russian annals mention Poltava in 1174 under the name of Ltava. In 1430 it was given, together with Glinsk, to the Tatar prince Leksada by Gediminas, prince of Lithuania. Under the Cossack chief, Bogdan Chmelnicki, it was the chief town of the Poltava "regiment".

Peter the Great defeated Charles XII of Sweden in the neighbourhood of Poltava in 1709.

POLTORATSK: see ASHKENABAD.

POLTROT, JEAN DE (c. 1537–1563), sieur de Méré or Méry, a nobleman of Angoumois, who murdered Francis, duke of Guise. He had lived some time in Spain, and his knowledge of Spanish, together with his swarthy complexion, which earned him the nickname of the "Españoleto," procured him employment as a spy in the wars against Spain. Becoming a fanatical Huguenot, he determined to kill the duke of Guise and gained admission as a deserter to the camp of the Catholics who were besieging Orléans. On Feb. 18, 1563, he hid by the side of a road along which he knew the duke would pass, fired a pistol at him and fled. He was captured the next day, tried, tortured and sentenced to be drawn and quartered. On March 18, 1563, he underwent a frightful punishment. The horses not being able to drag off his limbs, he was hacked to pieces with cutlasses. He had made several contradictory declarations regarding the complicity of Admiral Gaspard de Coligny, but his accusations seem to have had no foundation.

POLYAENUS, a Macedonian, who lived at Rome as a rhetorician and pleader in the 2nd century A.D. When the Parthian War (162–165) broke out, Polyaenus dedicated to the emperors Marcus Aurelius and Lucius Verus a work, still extant, called *Strategica* or *Strategemata*, a historical collection of stratagems and maxims of strategy written in Greek and strung together in the form of anecdotes. It is not strictly confined to warlike stratagems but includes also examples of wisdom, courage and cunning drawn from civil and political life. The work is divided into eight books (parts of the sixth and seventh are lost) and originally contained 900 anecdotes, of which 833 are extant. His works on Macedonia, on Thebes and on tactics (perhaps identical with the *Strategica*) are lost.

His *Strategica* seems to have been highly esteemed by the

Roman emperors and to have been handed down by them as a sort of herloom. From Rome it passed to Constantinople; at the end of the 9th century it was diligently studied by Leo VI, who himself wrote a work on tactics, and in the middle of the 10th century Constantine Porphyrogenitus mentioned it as one of the most valuable books in the imperial library. It was used by Stobaeus, Suidas and the anonymous author of the work *Περὶ πόλεως* (see PALAEPHIATVS). It is arranged as follows: bks i, ii, iii, stratagems occurring in Greek history; bk iv, stratagems of the Macedonian kings and successors of Alexander the Great; bk v, stratagems occurring in the history of Sicily and the Greek islands and colonies; bk vi, stratagems of a whole people (Carthaginians, Lacadaemonians, Argives), together with some individuals (Philopomen, Pyrrhus, Hannibal); bk vii, stratagems of the barbarians (Medes, Persians, Egyptians, Thracians, Scythians, Celts); bk viii, stratagems of Romans and women. This distribution is not, however, observed strictly. Of the negligence or haste with which the work was written there are many instances; e.g. he confounds Dionysius the elder and Dionysius the younger, Mithradates, satrap of Artaxerxes, and Mithradates the Great, Scipio the elder and Scipio the younger, Perseus, king of Macedonia, and Perseus, the companion of Alexander, he mixes up the stratagems of Caesar and Pompey, he brings into immediate connection events which were totally distinct; he narrates some events twice over, with variations according to the different authors from whom he draws. Though he usually abridges, he occasionally amplifies arbitrarily the narratives of his authorities. He never mentions his authorities, but among authors still extant he used Herodotus, Thucydides, Xenophon, Polybius, Diodorus, Plutarch, Frontinus and Suetonius, among authors of whom only fragments now remain he drew upon Ctesias, Ephorus, Timaeus, Philarchus and Nicolaus Damascenus. His style is clear but monotonous and inelegant. In the forms of his words he generally follows Attic usage.

The best edition of the text is Wolfen and Melber (Teubner series, 1887, with bibliography and edition princeps of the *Strategemata* of the emperor Leo); annotated editions by Isaac Casaubon (1589) and A. Corais (1860); I. Melber, *Über die Quellen und Werte der Strategemensammlung Polybius* (1865); Knott, *De fide et fontibus Polyani* (1883), Eng. trans. by R. Shepherd (1903).

POLYANDRY, the system under which a woman is married to several men at the same time (Gr. *πολύς*, many, and *ἀνὴρ*, man). Cases of it have been noticed among certain South American Indians, and in North America among some Eskimo, the Thlingit, the Aleut and the Kanaagmiut on the Alaskan coast. In an old description of the conquest of the Guanches in the Canary Islands in 1402 it is said that in the Island of Lancerote most of the women have three husbands, "who wait upon them alternately by months." Sporadic cases of polyandry have been found in Madagascar, among a few peoples on the African continent, in some places of the Malay archipelago and among certain South Sea islanders, while in the Marshall Islands and the Marquesas it has been practised on a much larger scale. In Tibet polyandry has prevailed from time immemorial, the husbands being as a rule brothers, who live together with their common wife as members of the same household. Fraternal polyandry is more or less frequent in vast districts of the Himalayan region from Assam to the dependencies of Kashmir, chiefly among people of Tibetan affinities, and in South India, where its prevalence among the Todas of the Nilgiri hills has attracted special attention; and it existed throughout the interior of Ceylon until it was prohibited by the British government about the year 1860. Among the Nayars or Nairs of Cochín, Malabar and Travancore we meet with polyandrous unions of a different, nonfraternal type, the prevalence of which has been testified by a large number of travellers from the beginning of the 15th century onward. According to Nayar usage every girl, before she attained puberty, was subjected to a certain marriage ceremony, after which the nominal husband went his way and she was allowed to cohabit with any Brahman or Nayar she chose; usually she had several lovers, who cohabited with her by agreement among themselves but did not live with her. Strabo asserts that polyandry prevailed in Arabia Felix, and some modern scholars think that they have

found confirmation of this statement in Sabian and Minaean inscriptions.

Frequently, polyandry is modified in a monogamous direction, one, usually the first, husband being the chief husband, in various cases any other man with whom he shares his wife acts as husband and master of the house only during the absence of the true lord. Where fraternal polyandry prevails, the eldest brother is commonly regarded as the principal husband, he chooses the wife, and the contract he makes may implicitly confer matrimonial rights on all the other brothers. Among many polyandrous peoples the various husbands live or cohabit with their common wife in turn; and if they are brothers, the eldest one is sometimes expressly said to take the lead.

Among many polyandrous peoples there are said to be more men than women, and their polyandry has in several cases been directly attributed to this fact, and even it some of these statements, in the absence of statistical data, are more or less hypothetical, there are others the accuracy of which is past all doubt. But polyandry has also been traced to economic motives. In Tibet it has been said to obtain as a necessary institution, serving the end of checking the increase of population in regions from which emigration is difficult and also keeping the family property together, and similar reasons have been assigned for polyandry in Ladakh, Bhutan, South India and Ceylon. The polyandry of the Tibetans, the Himalavans and some peoples in the south of India seems also to be partly because of the dangers or difficulties which would surround a woman left alone in her home during the prolonged absence of her husband. The peculiar polyandry of the Nayars is most probably connected with their military organization, which prevented their living the ordinary life of a husband and father of a family.

POLYBIUS (c. 201–c. 120 B.C.), Greek historian, was born at Megalopolis in Arcadia, being the son of Lycortas, the friend and successor of Philopomen as leader of the Achaean league. The precise dates of his birth and death are not known, but they can be inferred approximately. We have his own statement (xxiv, 6) that in 181 B.C., when he was appointed along with Lycortas and Aratus as an ambassador to Egypt, he was still under the legal age, which appears to have been 30 (xxx, 9). According to Cicero, *Ad Fam.*, v, 12, Polybius wrote a special history of the Numantine War, which ended in 132 B.C. Lastly, in Lucian, *Macrob.* 22, we read that he died in consequence of a fall from his horse at the age of 82.

The more notable events of his life may be briefly stated. As the son of Lycortas he was naturally brought into close contact with the leading men of the Achaean league. With Philopomen he seems to have been on intimate terms. After Philopomen's tragic death in Messenia (184 B.C.), he was entrusted with the honourable duty of conveying home the urn in which his ashes had been deposited (Plutarch, *Philopomen* 21). In 181, as noted above, he was appointed, in spite of his youth, a member of the embassy which was to visit Ptolemy Epiphanes, king of Egypt, a mission, however, which the sudden death of Ptolemy brought to a premature end (xv, 7). The next 12 years of his life are a blank, but in 169 he reappears as a trusted adviser of the Achaeans at a difficult crisis in the history of the league. In 171 war had broken out between Rome and the Macedonian king Perseus, and the Achaean statesmen were divided as to the policy to be pursued; there were good reasons for fearing that the Roman senate would regard neutrality as indicating a secret leaning toward Macedon. Polybius therefore declared for an open alliance with Rome, and his views were adopted. It was decided to send an Achaean force to assist the Roman consul Q. Marcus, and Polybius was appointed to command the cavalry. He was also one of the envoys who were

sent to consult with the consul, and, although the proffered assistance was declined, he remained for a time in the Roman camp (xxvii 13). The turning point in his life came when Perseus was finally defeated by the Romans at Pydna in 168. Polybius was one of 1,000 leading Achaean who were carried to Rome, at the instigation of Callicrates, on the charge of having been lukewarm in their support of the Roman cause.

While the others were distributed among the Italian towns, Polybius was allowed, through the influence of L. Aemilius Paulus, and his sons Fabius (Q. Fabius Maximus Aemilianus) and Scipio (P. Cornelius Scipio Africanus minor) to remain in Rome (xxci 9, Pausan. vii 10 2). With Scipio he formed a close friendship and to his influence with Scipio it was due that in 151 B.C., the remnant of the Achaean exiles obtained permission to return to their homes (xxcv 6). Polybius himself, after a short stay in Achaia, joined Scipio in Africa in 147 and was present at the siege and destruction of Carthage in 146. Meanwhile the mistaken attempt of the Achaean League to assert its independence of Rome had ended in disaster and the remaining public work of Polybius was devoted to alleviating so far as possible for his countrymen the consequences of their policy, and to facilitating the establishment of order under the new régime (xl 8-10).

The manner in which he accomplished this was such as to earn the gratitude of his compatriots, as was attested by the statues erected in his honour at Mantinea (Pausan. viii 9. 1), Palantium (Pausan. viii 44 5), Tegea (Pausan. viii 48. 8), Megalopolis (Pausan. viii 30 8)—where the inscription recorded that he "had roamed over all the earth and sea, and had been the ally of the Romans and had made them cease from their anger against Greece"—Acacusum, the inscription declaring that "Hellas would never have come to grief, if she had obeyed Polybius in all things, and, having come to grief, she found succour through him alone" (Pausan. viii 87 2). The base of a statue erected to him by Elis was discovered at Olympia in 1877 with the inscription.

ἡ πόλις ἡ Ἡλείω Πολύβιον Δωδῶνα Μεγαλοπόλιν.

The *Histories* (*Ἱστορίαι*), on which his reputation as a historian now rests, were in 40 books. Of these the first five are extant. For the remaining books we have excerpts from a collection of passages from the Greek historians, which was made by the order of Constantine Porphyrogenitus in the 10th century, excerpts of vi-xvii contained in another compilation of uncertain date, first printed at Basle in 1549, and a fragment of xi, 13-16, in a Berlin papyrus (3rd century A.D.).

The original intention of Polybius was to narrate the history of the 53 years (220-168 B.C.)—from the beginning of the Hannibalic War to the defeat of Perseus at Pydna—in which Rome made herself mistress of the world. The first two books are prefatory—a "preparation" (προκατασκευή I 3)—dealing with the earlier history of Rome, the first Punic War, and contemporary events in other parts of the world. But the opening chapter of Book III indicates an intention to modify his original plan by adding an account of the manner in which the Romans exercised their supremacy down to the destruction of Carthage in 146 B.C. Thus the history of the period 168-146 B.C. appears to have occupied the last ten books.

Scientific Conception of History.—With regard to the function of the historian, Polybius is one of those who consider history to be—in the phrase of Dionysius—"philosophy teaching by examples." Thus he says in i. 35: "Whereas there are for all men two ways of improvement, to wit by one's own disasters or those of others, the former is the more vivid, the latter is the less harmful. Therefore, one should never willingly choose the former, since the improvement which it brings is fraught with great danger and pain, but one should always pursue the latter, since in it one can discern the better way without hurt. And it is therefore to be considered that the best education for real life is the knowledge of affairs which accrues from practical history (*πραγματικὴ ἱστορία*) which alone, without personal hurt, makes men on every occasion and in all circumstances, true judges of the better way."

From this conception of history, which differs little, if at all, from that of Thucydides or the modern historian of the scien-

tific school, it follows that the chief interest lies, not in the question of origins, in the legendary or semi-legendary traditions, by which states or nations, like individuals, when they have achieved greatness, are fain to decorate their origins, but in the actual transactions of historical times, the plain matters of fact which appeal to the plain man. This seems to be undoubtedly what Polybius means by the term "pragmatic" by which his several times characterizes his *History*. Thus in criticizing Phylarchus he writes (ii 56. 7 seq.) "Endeavouring to excite his readers to pity and to make them sympathetic with his narrative, he introduces embracing of wives, disordered hair, bawling of breasts, tears and lamentations of men and women haled away with their children and aged parents. Thus he does throughout his whole history, seeking always to give a vivid picture of horrors. The ignoble femininity of this design may be left out of the question; but we must consider what is proper and profitable in history. It is the function of the historian not to astonish his readers by prodigies nor to hunt up all possible tales and recount all the concomitants of his subjects, as tragedians do, but to narrate in their verity the things actually done and said, how modest soever they may be. For the end of history is not identical with that of tragedy, but quite the contrary. In tragedy the end is by the most plausible language to astonish and move the audience temporarily. In history the end is by real facts and real speeches to instruct and persuade for all time the lovers of knowledge since in the former the leading motive is the plausible, even if the plausible be false, for the deception of the spectators, in the latter the leading motive is truth for the benefit of the student."

What Polybius himself means by "Pragmatic history" (i 2 πρόσκαιρα πηλίκαι συμβάλλουσιν πρὸς τοῖς φιλομαθοῦσιν ὁ τῆς πραγματικῆς ἱστορίας τρόπος) is illustrated by his remarks (ii. 47) on those who have written of Hannibal's crossing of the Alps. "Wishing to astonish their readers by their marvellous account of the localities, they fall into two faults which are most foreign to all history; for they are compelled to tell falsehoods (*ψευδολογῶν*) and to contradict themselves. On the one hand they introduce Hannibal as a general of inimitable daring and prudence, while they show him admittedly the most imprudent; and on the other hand, unable to reach a dénouement or an issue from their own mendacity, they introduce into pragmatic history gods and the children of gods. . . . Ignorant of these things they say that a hero (*ἥρως*, a demigod) appeared and showed the Carthaginians the roads. Hence, naturally, they find themselves in the same position as the writers of tragedies. For the dénouements of their dramas need a god and a machine, because their first premises are false and contrary to reason; and historians must be in like case and must represent gods and heroes appearing when their premises are improbable and false."

Polybius (ii 6) insists on the distinction between the remoter causes (*αἰτίαι*) of events and their immediate origins (*ἀρχαί*) and in the same spirit he emphasizes the necessity of taking a comprehensive or synoptic view of history, regarding history as a unity in so far as the interests of different nations mutually interact. "In previous times the actions of the world were sporadic. . . now history is, as it were, an organic whole; the affairs of Italy and Africa are intertwined with those of Asia and Greece and all have reference to one end" (i 3). It is this conception of history which leads Polybius to prefix to his more immediate subject the preparatory narrative of his first two books. "The peculiarity of our study and the marvel of our times is this. Just as Fortune (*τύχη*) has bent almost all the affairs of the world to one end and has inclined them to one and the same goal, so by means of history we must bring under one conspectus for our readers the agency which Fortune has employed to accomplish the whole. For this consideration it is chiefly which incited and stimulated me to undertake my history, coupled with the fact that no one in our time has attempted a general history: otherwise I had been much less eager in this direction. But when I see that many writers occupy themselves with particular wars and some of the actions connected with them, while no one, so far as I know, has even attempted to examine

the general and comprehensive economy of events—when and whence they originated and how they attained fulfilment—I considered it absolutely essential not to omit or allow to pass unnoticed the most beautiful and at the same time the most beneficial exhibition of the power of Fortune. For many as are her innovations and unceasingly as she engages in the affairs of men, absolutely never has she wrought such a work or engaged in such a struggle as in our time. This cannot be seen from sectional histories—unless it be that one who visits the most eminent individual cities or sees them represented in a picture, imagines straightway that he understands the form of the whole world, and its general position and arrangement" (i 4).

Sources of Information.—Starting with the initial advantage of being himself conversant with public affairs, Polybius seems to have taken pains unusual for his time to equip himself with the knowledge requisite to ensure accuracy. In the first place he was a careful student of the practice of war, and indeed wrote a treatise on *Tactics* (ix 20 4 cf. Arrian, *Tact.* i 1, Aelian, *Tact.* i 2, iii 4, xiv 10). He had an extensive first-hand acquaintance with geography (cf. the inscription on his statue at Megalopolis as quoted above); he accompanied Scipio in many campaigns (Arrian, *Tact.* 1c) and, as he tells us himself, "it was mainly for this reason that I undertook the dangers and discomforts incident to travel in Africa and Spain and also Gaul and the Outer Sea (Atlantic) adjacent to those lands, in order that I might correct the ignorance of my predecessors in those matters and make known those parts of the world to the Greeks" (iii 59). He also tells us (iii 48) in discussing Hannibal's passage of the Alps, that he had himself seen the region and had travelled over the Alps for the sake of information and observation. His intimate study of constitutional matters is shown by his account of the Roman constitution in Book VI. Finally he made diligent use of the documentary and monumental evidence accessible to him. Thus in ii 33, after giving the numbers of Hannibal's forces with a detail "suggesting the plausible mendacity of a historian" he explains that he took the numbers from a record in bronze left at Lacinium (in Bruttium) by Hannibal himself. In xvi 15 he appeals to the evidence of a despatch preserved in the *prytaneum* of Rhodes, and the manner in which he quotes the terms of the treaty which ended the first Punic War (i 62) and of that between Hannibal and Philip (vii 9) implies that he is either translating or quoting a translation of an original document which he possibly obtained from official sources.

His enlightened conception of the function of history, his careful preparation for his task, entitle Polybius to an honourable place among historians. The completely impartial historian is an ideal, certainly unattainable and perhaps undesirable. No very serious charge on this ground is made against Polybius, nor can such charges in any case be either confuted or confirmed authoritatively. He has himself at all events forestalled criticism. "That historians may incline the balance in favour of their own country I would allow—not that they should make statements which contradict the facts. There are enough errors of ignorance to which historians are liable and which a man may hardly avoid. But if we write falsely from intention—be it for country or for friends or for favour—what better is there than those who make their living by such means?" On this tendency readers should keep a watchful eye, and historians themselves should guard against it" (xvi 14).

The main criticism directed against Polybius from Dionysius of Halicarnassus (1st century, B.C.) to the present day is made on the ground of style. Dionysius, from the standpoint of a strict Atticist, writes of the later Greek historians who have so far neglected style that they "have left behind them compositions which no one endures to read to the end—Phylarchus, Duris, Polybius" (Dionys *De comp. verb.* iv). The modern reader, from a more general standpoint, would be inclined to think that his defects of style have been exaggerated. But his unfamiliar vocabulary, his intentional rejection of the picturesque concomitants of historical events, his anxiety to point a moral, combine to render him less popular than his merits deserve. One more proof that something more than knowledge, more than accuracy,

more than serious purpose and moral earnestness, is required in the historian to whom the world will gladly listen.

POLYCARP (c. 69–c. 155), bishop of Smyrna and one of the Apostolic Fathers, derives much of his importance from the fact that he links together the apostolic age and that of nascent Catholicism. The sources from which we derive our knowledge of the life and activity of Polycarp are: (1) a few notices in the writings of Irenaeus, (2) the *Epistle of Polycarp to the Church at Philippi*, (3) the *Epistle of Ignatius to Polycarp*, (4) the *Epistle of the Church at Smyrna to the Church at Philocheim*, giving an account of the martyrdom of Polycarp. Since these authorities have all been more or less called in question and some of them entirely rejected by recent criticism, it is necessary to say a few words about each.

Sources.—The *Statements of Irenaeus* are found (a) in his *Adversus haereses*, ii, 3, 4, (b) in the letter to Victor, where Irenaeus

the Ignatian letters and is now generally fixed between 112 and 118. The language in this letter is simple but powerful.

3. *The Epistle of Ignatius to Polycarp.*—This epistle has of course been subjected to the same criticism as has already been directed against the other epistles of Ignatius (see IGNATIUS), the general criticism, may now be said to have been completely answered by the investigations of Zahn, Lightfoot and Harnack. Some modern scholars feel a difficulty about the peremptory tone which Ignatius adopts towards Polycarp. There was some force in this argument when the Ignatian Epistles were dated about 140, as in that case Polycarp would have been an old and venerable man at the time. But now that the date is put back to about 112 the difficulty vanishes, since Polycarp was not much over forty when he received the letter.

4. *The Letter of the Church at Smyrna to the Philomelians* is a most important document, because we derive from it all our information with regard to Polycarp's martyrdom. Eusebius has preserved the greater part of this epistle (iv 15), but we possess it entire with various concluding observations in several Greek mss., and also in a Latin translation. The epistle gives a minute description of the persecution in Smyrna, of the last days of Polycarp and of his trial and martyrdom, and as it contains many instructive details and professes to have been written not long after the events to which it refers, it has always been regarded as one of the most precious remains of the 2nd century. Certain recent critics, however, have questioned the authenticity of the narrative. The more moderate school of modern critics—e.g., Lightfoot (*Ignatius and Polycarp*, 1899, 1907), Harnack (*Gesch. d. altchristl. Lit.* II, i 341), and Kruger (*Early Christian Lit.*, 1897)—is unanimous in regarding it as an authentic document, though it recognizes that here and there a few slight interpolations have been inserted. Besides these we have no other sources for the life of Polycarp.

Life.—Polycarp must have been born not later than the year 69, for on the day of his death (c. 155) he declared that he had served the Lord for eighty-six years (*Martyrium*, 9). Irenaeus tells us that in early life Polycarp "had been taught by apostles and lived in familiar intercourse with many that had seen Christ" (iii 3, 4).

This testimony is expanded in the remarkable words which Irenaeus addressed to Florinus:

"I saw thee when I was still a boy (καὶ ἄρα) in Lower Asia in company with Polycarp. I can even now point out the place where the blessed Polycarp used to sit when he discoursed, and describe his goings out and his comings in, his manner of life and his personal appearance, and the discourses which he delivered to the people, how he used to speak of his intercourse with John and with the rest of those who had seen the Lord, and how he would relate their words. And everything that he had heard from them about the Lord, about His miracles and

about His teaching, Polycarp used to tell us as one who had received it from those who had seen the Word of Life with their own eyes, and all this in perfect harmony with the Scriptures. To these things I used to listen at the time, through the mercy of God vouchsafed to me, noting them down, not on paper but in my heart, and constantly by the grace of God I brood over my accurate recollections."

These words establish a chain of tradition (John-Polycarp-Irenaeus) which is without a parallel in early church history. Polycarp thus becomes the living link between the Apostolic age and the great writers who flourished at the end of the 2nd century. Recent criticism, however, has endeavoured to destroy the force of the words of Irenaeus. Harnack (*Chronologie*, i, 325-329), for instance, attacks this link at both ends. (a) The connection of Irenaeus and Polycarp, he argues, is very weak, because Irenaeus was only a boy (παις) at the time, and his recollections therefore carry very little weight. The fact, too, that he never shows any signs of having been influenced by Polycarp and never once quotes his writings is a further proof that the relation between them was slight. (b) The connection which Irenaeus tries to establish between Polycarp and John the apostle is probably due to a blunder. Irenaeus has confused John the apostle and John the presbyter. Polycarp was the disciple of the latter, not the former. In this second argument Harnack has the support of a considerable number of modern scholars who deny the Ephesian residence of John the apostle. But in spite of much modern criticism there seems to be no solid reason for rejecting the statements of Irenaeus and regarding Polycarp as the link between the Apostolic age and the first of the Catholic fathers.

Though Polycarp must have been bishop of Smyrna for nearly half a century we know next to nothing about his career. We get only an occasional glimpse of his activity, and the period between 115 and 155 is practically a blank. The only points of sure information which we possess relate to (1) his relations with Ignatius, (2) his protests against heresy, (3) his visit to Rome in the time of Anicetus, (4) his martyrdom.

His Relations with Ignatius.—Ignatius, while on his way to Rome to suffer martyrdom, halted at Smyrna and received a warm welcome from the church and its bishop. Upon reaching Troas he despatched two letters, one to the church at Smyrna, another addressed personally to Polycarp. In these letters Ignatius charged Polycarp to write to all the churches between Smyrna and Syria (since his hurried departure from Troas made it impossible for him to do so in person) urging them to send letters and delegates to the church at Antioch to congratulate it upon the cessation of the persecution and to establish it in the faith. The letters of Ignatius illustrate the commanding position which Polycarp had already attained in Asia. It was in the discharge of the task which had been laid upon him by Ignatius that Polycarp was brought into correspondence with the Philippians. The Church at Philippi wrote to Polycarp asking him to forward their letters to Antioch. Polycarp replied, promising to carry out their request and enclosing a number of the letters of Ignatius which he had in his possession.

Polycarp's Attack on Heresy.—All through his life Polycarp appears to have been an uncompromising opponent of heresy. We find him in his epistle (ch. vi) uttering a strong protest against certain false teachers (probably the followers of Cerinthus).

For every one who shall not confess that Jesus Christ is come in the flesh is antichrist; and whosoever shall not confess the testimony of the Cross is of the devil, and whosoever shall pervert the oracles of the Lord to his own lusts and say that there is neither resurrection nor judgment, that man is the first-born of Satan. Wherefore let us forsake their vain doing and their false teaching and turn unto the word which was delivered unto us from the beginning.

Polycarp lived to see the rise of the Marcionite and Valentinian sects and vigorously opposed them. Irenaeus tells us that on one occasion Marcion endeavoured to establish relations with him and accosted him with the words, "Recognize us." But Polycarp displayed the same uncompromising attitude which his master John had shown towards Cerinthus and answered, "I recognize you as the first-born of Satan." The steady progress of the heretical movement in spite of all opposition was a cause of deep sorrow to Polycarp, so that in the last years of his life the words were

constantly on his lips, "Oh good God, to what times hast thou spared me, that I must suffer such things!"

Polycarp's Visit to Rome.—It is one of the most interesting and important events in the church history of the 2nd century that Polycarp, shortly before his death, when he was considerably over eighty years old, undertook a journey to Rome in order to visit the bishop Anicetus Irenaeus, to whom we are indebted for this information (*Haer.* iii, 3, 4, *Epist. ad victorem*, ap. Euseb. v, 24), gives as the reason for the journey the fact that differences existed between Asia and Rome "with regard to certain things" and especially about the time of the Easter festival. Unfortunately all he says is that with regard to the certain things the two bishops speedily came to an understanding, while as to the time of Easter, each adhered to his own custom, without breaking off communion with the other. We learn further that Anicetus as a mark of special honour allowed Polycarp to celebrate the Eucharist in the church, and that many Marcionites and Valentinians were converted by him during his stay in Rome.

Polycarp's Martyrdom.—Not many months apparently after Polycarp's return from Rome a persecution broke out in Asia. A great festival was in progress at Smyrna. The proconsul Statius Quadratus was present on the occasion, and the asarch Philip of Tralles was presiding over the games. Eleven Christians had been brought, mostly from Philadelphia, to be put to death. The appetite of the populace was inflamed by the spectacle of their martyrdom. A cry was raised, "Away with the atheists! Let search be made for Polycarp." Polycarp took refuge in a country farm. His hiding-place, however, was betrayed and he was arrested and brought back into the city. Attempts were made by the officials to induce him to recant, but without effect. When he came into the theatre, the proconsul urged him to "revile Christ," and promised, if he would consent to abjure his faith, that he would set him at liberty. To this appeal Polycarp made the memorable answer, "Eighty and six years have I served Him and He hath done me no wrong. How then can I speak evil of my King who saved me?" These words only intensified the fury of the mob. They clamoured for a lion to be let loose upon him there and then. The asarch, however, refused, urging as an excuse that the games were over. When they next demanded that their victim should be burned, the proconsul did not interfere. Timber and faggots were hastily collected and Polycarp was placed upon the pyre. With calm dignity and unflinching courage he met his fate and crowned a noble life with an heroic death.

Eusebius in his *Chronicon* gives A.D. 166 as the date of Polycarp's death, and until the year 1867 this statement was never questioned. In that year appeared Waddington's *Mémoire sur la chronologie de la vie du rhéteur Aélius Aristide*, in which it was shown from a most acute combination of circumstances that the Quadratus whose name is mentioned in the *Martyrium* was proconsul of Asia in 155-156, and that consequently Polycarp was martyred on Feb. 23, 155. Waddington's conclusion has received overwhelming support amongst recent critics. His views have been accepted by (amongst many others) Renan (*Antéchrist*, 1873, p. 207), Hügelfeld (*Zeitschr. f. Wiss. Theol.*, 1874, p. 325), Gebhardt (*Zeitschr. f. Hist. Theol.*, 1875, p. 356), Lipsius (*Jahrb. f. prot. Theol.*, 1883, p. 525), Harnack (*Chronologie*, i, 334-356), Zahn (*Zeitschr. f. Wiss. Theol.*, 1882, p. 227), Lightfoot (*Ignatius and Polycarp*, i, 629-702) and Randall (*Studia biblica*, 1885, i, 175). Against this array of scholars only the following names of importance can be quoted in support of the traditional view—Keim (*Aus dem Urchristentum*, p. 90), Wieseler (*Die Christenverfolgungen der Caesaren*, 1878, p. 34) and Uhlhorn (*Studia biblica*, 1890, ii, 105-156). The problem is too complex to admit of treatment here. There seems to be little doubt that the case for the earlier date has been proved.

The significance of Polycarp in the history of the Church is out of all proportion to our knowledge of the facts of his career. The violent attack of the Smyrnaean mob is an eloquent tribute to his influence in Asia. "This is the teacher of Asia," they shouted, "this is the father of the Christians: this is the destroyer of our gods: this is the man who has taught so many no longer to sacrifice and no longer to pray to the gods." And after the execu-

tion they refused to deliver up his bones to the Christians for burial on the ground that "the Christians would now forsake the Crucified and worship Polycarp." Polycarp was indeed, as Poly-crates says, "one of the great luminaries" (μεγάλα σπουδαία) of the time. It was in no small degree due to his staunch and unwavering leadership that the Church was saved from the peril of being overwhelmed by the rising tide of the pagan revival which swept over Asia during the first half of the 2nd century, and it was his unflinching allegiance to the Apostolic faith that secured the defeat of the many forms of heresy which threatened to destroy the Church from within.

Polycarp had no creative genius. He was a "transmitter, not a maker." As Irenaeus says (iii. 3, 4), "Polycarp does not appear to have possessed qualifications for successfully conducting a controversial discussion with erroneous teachers . . . but he could not help feeling how unlike their speculations were to the doctrines which he had learned from the Apostles, and so he met with indignant reprobation their attempt to supersede Christ's gospel with fictions of their own devising." It is this that constitutes Polycarp's service to the Church, and no greater service has been rendered by any of its leaders in any age.

BIBLIOGRAPHY.—J. B. Lightfoot, *Apostolic Fathers*, pt. ii (2nd ed., 1889). Polycarp is dealt with in i. 137-459, 530-704, ii. 897-1086, G. Vollmar, *Epistula Polycarpi Smyrnae gentium* (Zurich, 1885), T. Zahn, *Forschungen zur Geschichte des Kanons*, etc., iv. 249, 279, J. M. Cotterill, "The Epistle of Polycarp to the Philippians," *Journal of Philol.* (1891), xiv. 241-285, Harnack, *Chronologie der altchristlichen Literatur* (1897), and authorities quoted in the text. See also *APOSTOLIC FATHERS* (H. T. A., X).

POLYCHAETA, a class of segmented, largely marine worms (Annelida, q.v.). They comprise 64 families and nearly 10,000 species. The name refers to the serially arranged tufts of bristles at the sides of the body. Examples are *Nereis* and *Serpula*.

POLYCLEITUS, the name of two Greek sculptors of the school of Argos, the first belonging to the fifth century, the second to the early part of the fourth.

The elder and best known Polycleitus was a contemporary of Pheidias, and in the opinion of the Greeks his equal. Whether he was actually a pupil of Ageladas is disputed; at any rate he earned on the tradition. He made a figure of an Amazon for Ephesus which was regarded as superior to the Amazon of Pheidias made at the same time, and his colossal Hera of gold and ivory which stood in the temple near Argos was considered as worthy to rank with the Zeus of Pheidias. It would be hard for a modern critic to rate Polycleitus so high; the reason is that balance, rhythm and the minute perfection of bodily form, which were the great merits of this sculptor, do not appeal to us as they did to the Greeks of the 5th century. He worked mainly in bronze.

As regards his chronology we have data in a papyrus published by Grenfell and Hunt containing lists of athletic victors. From this it appears that he made a statue of Cyniscus, a victorious athlete of 464 or 460 B.C., of Pythocles (452) and Aristion (452). He thus can scarcely have been born as late as 480 B.C. His statue of Hera is dated by Pliny to 420 B.C. His artistic activity must thus have been long and prolific. His two great statues, ideal athletic types rather than portraits, are the Diadumenes and the Doryphorus, copies of both of which are common. The Doryphorus was known as the Canon, because it embodied the correct proportions of the ideal male form. The completest copy is from Pompeii, and there is a copy of the Diadumenes from Vaison in the British Museum. Both are late Roman copies, unpleasantly heavy and square and in marble, thus giving little idea of the finish of Polycleitus' work in bronze. This has been enforced by the discovery at Delos, by the French excavators, of a diadumenes of far more pleasing type and greater finish, which also goes back to Polycleitus. The excavations at Olympia have widened our knowledge of his early work. Among the bases of statues found on that site were three signed by Polycleitus, still bearing on their surface the marks of attachment of the feet of the statues. This at once gives us their pose, and following up the clue, A. Furtwängler has identified several extant statues as copies of figures of boy athletes victorious at Olympia set up by Polycleitus. Among these the Westmacott athlete in the British Museum is

conspicuous.

The Amazon of Polycleitus survives in several copies, among the best of which is one in the British Museum. The masterpiece of Polycleitus, his Hera of gold and ivory, has of course totally disappeared. The coins of Argos give us only the general type. Waldstein has identified the head of a girl in the British Museum as belonging to this type.

The want of variety in the works of Polycleitus was brought as a reproach against him by ancient critics. Varro says that his statues were square and almost of one pattern. Except for the statue of Hera, which was the work of his old age, he produced scarcely any notable statue of a deity. His field was narrowly limited, but in that field he was unsurpassed.

2 The younger Polycleitus was of the same family as the elder, and the works of the two are not easily to be distinguished. Some existing bases, however, bearing the name are inscribed in characters of the 4th century, at which time the elder sculptor cannot have been alive.

See A. Furtwängler, *Masterpieces of Greek Sculpture* (Eng. trans. 1895), P. Paris, *Polycleite* (Paris, 1895); Mahler, *Polyklit und seine Schule* (Athens, 1902).

POLYCRATES, tyrant of Samos (c. 535-515 B.C.). Having won popularity by donations to poorer citizens, he took advantage of a festival of Hera, which was being celebrated outside the walls, to make himself master of the city (about 535 B.C.). After getting rid of his brothers Pantagnotus and Sylosion, who had at first shared his power, he established a despotism which is of great importance in the history of the island. He equipped a fleet of 100 ships and so became master of the Aegean basin. This ascendancy he abused by numerous acts of piracy which made him notorious throughout Greece; but his real aim was the control of the archipelago and the mainland towns of Ionia. He maintained an alliance with Lygdamis of Naxos, and dedicated to Delos the island of Rhenea. He also defeated a coalition of two great naval powers of the Asiatic coast, Miletus and Lesbos. He made an alliance, probably commercial in object, with Amasis of Egypt. But the squadron he sent to Amasis' support against Cambyses of Persia, being composed of political opponents of Polycrates, suspected treachery and returned and attacked Polycrates. After a defeat by sea, Polycrates repelled an assault upon the walls, and subsequently withstood a siege by a joint armament of Spartans and Corinthians assembled to aid the rebels. He maintained his ascendancy until about 515, when Oroetes, the Persian governor of Lydia, who had been reproached for his failure to reduce Samos by force, lured him to the mainland and put him to death by crucifixion.

Beside the political and commercial pre-eminence which he conferred upon Samos, Polycrates adorned the city with public works on a large scale. He was also a patron of letters; he collected a library, and Anacreon lived at his court.

POLYGALACEAE, a family of dicotyledonous herbs, shrubs and small trees, comprising ten genera and about 700 species, not represented in New Zealand, Polynesia and the Arctic zone, but otherwise cosmopolitan. *Polygala vulgaris* is the British milkwort (q.v.), and *P. Senega*, the Senega snake-root, a North American medicinal plant. In North America some 50 species are found, chiefly in the southern and western United States.

POLYGLOTT or **POLYGLOT**, a book which contains side by side versions of the same text in several languages (Gr. πολυγλωττα, many, and γλῶττα, tongue). The most important polyglotts are editions of the Bible, or its parts, in which the Hebrew and Greek originals are exhibited along with the great historical versions. The famous *Hexapla* of Origen, in which the Old Testament Scriptures were written in parallel columns, probably suggested the later polyglotts, but though it gives six texts it is itself only in two languages. In the 16th and 17th centuries polyglotts became a favourite means of advancing the knowledge of Eastern languages as well as the study of Scripture. The series began with the *Complutensian* printed by Arnaldus Guelmus de Brocario at the expense of Cardinal Jimenez (q.v.) at the university at Alcalá de Henares (Complutum). This contained for the Old Testament the Hebrew text, Latin Vulgate and the Septuagint

and Chaldee versions with Latin renderings, for the New Testament, the Greek and Vulgate Latin. The six volumes bear dates ranging from Jan. 10, 1514, to July 10, 1517, but the work did not receive the papal sanction till March 1520, and was apparently not issued till 1522, probably because of the Imperial privilege obtained by Erasmus for his Greek Testament in 1516. The *Antwerp Polyglott*, printed by Christopher Plantin (1569-72, in 8 vols folio), under the patronage of Philip II of Spain, added a new language to those of the *Complutensian* by including the Syriac New Testament. Next came Le Jay's *Paris Polyglott* (1645), which embraces the first printed texts of the Syriac Old Testament and of the Samaritan Pentateuch. It has also a series of various Arabic versions. The last great polyglott was that edited by Brian Walton, published in London in 1667. This is much less beautiful than Le Jay's, but includes the Syriac of Esther and of several apocryphal books, Persian versions of the Pentateuch and Gospels, and the Psalms and New Testament in Ethiopic. It was in connection with this polyglott that E. Vassell produced his famous *Heptaglot Lexicon* (2 vols. 1690, London, 1696). Of the numerous polyglott editions of parts of the Bible it may suffice to mention the Genoa psalter of 1516, edited by Giustiniani, bishop of Nebbio. This is in Hebrew, Latin, Greek, Chaldee and Arabic, and is interesting from the character of the Chaldee text, being the first specimen of western printing in the Arabic character. (A. W. P.)

POLYGNOTUS, famous Greek painter, c. 470-440 B.C., son of Aglaophon, was a native of Thasos, but was adopted by the Athenians, and admitted to their citizenship. He painted for them, in the time of Cimon, a picture of the taking of Ilium on the walls of the Stoa Poecile, and another of the marriage of the daughters of Leucippus in the Anaceum. In the hall at the entrance to the Acropolis other works of his were preserved, and he collaborated with Mikon in paintings of Greeks and Amazons in the Theseum. The most important, however, of his products were his frescoes in the Lesche erected at Delphi by the people of Cridus. The subjects of these were the visit to Hades by Odysseus, and the taking of Ilium. Fortunately the traveller Pausanias has left us a careful description of these paintings, figure by figure (Paus. x, 25-31), and we may form some idea of their style from contemporary vase decorations. The foundations of the building have been recovered in the course of the French excavations at Delphi. From this evidence some modern archaeologists have tried to reconstruct the composition of the paintings. The figures were detached and seldom overlapping, ranged in two or three rows one above another, and the farther were not smaller nor dimmer than the nearer. We learn also that Polygnotus employed but few colours. His excellence lay in the beauty of his drawing of individual figures, but especially in the "ethical" and ideal character of his art. His work must have had the same grandeur as the contemporary sculptures of Olympia, combined apparently with a new delicacy, for he is praised for his transparent garments, his head-dresses of variegated colours, and his speaking expressions. He was the great representative of Greek painting of the 5th century B.C., as Pheidias was of sculpture.

POLYGONACEAE, in botany, a family of dicotyledons, containing 40 genera with about 50-800 species, chiefly in the north temperate zone, and represented in Great Britain by three genera, *Polygonum*, *Rumex* (dock, *q.v.*) and *Oxyria*. They are mostly herbs characterized by the union of the stipules into a sheath or *ocrea*, which protects the younger leaves in the bud stage. Some are climbers, as, for instance, the British *Polygonum convolvulus* (black bindweed). In *Muehlenbeckia platyclada*, a native of the Solomon Islands, the stem and branches are flattened, forming ribbon-like cladodes jointed at the nodes. The leaves are alternate, simple and generally entire; the edges are rolled back in the bud. They are generally smooth, but sometimes, especially in mountain species, woolly. The small, regular, generally hermaphrodite flowers are borne in large numbers in compound inflorescences, the branches of which are cymose. The parts of the flower are whorled (*cyclic*) or *syclic*. The former arrangement may be derived from a regular trimerous flower with two whorls of perianth leaves, two staminal whorls and a three-sided ovary—

this type of flower occurs in the Californian genus *Pterostegia*. The flower of rhubarb (*Rheum*) is derived from this by doubling in the outer staminal whorl and that of the dock (*Rumex*) by doubling in the outer staminal whorl and suppression of the inner whorl. Numerous whorled flowers occur in *Oxyria* (mountain sorrel), another arctic and alpine genus, the flowers of which otherwise resemble those of *Rumex*. In the acyclic flowers a pentamerous perianth is followed by five to eight stamens as in *Polygonum*. The perianth leaves are generally uniform and green white or red in colour. They are free or more or less united, and persist till the fruit is ripe, often playing a part in its distribution, and affording useful characters for distinguishing genera or species. Thus in the docks the three inner leaves enlarge and envelop the fruit as three membranous wings one or more of which bear on the back large fleshy warts. The number of the carpels is indicated by the three-sided (in dimerous flowers two-sided) ovary, and the number of the styles; the ovary is unilocular and contains a single erect ovule springing from the top of the floral axis. The fruit is a dry one-seeded nut, two-sided in *Urticaceae* flowers, is in *Oxyria*. The straight or curved embryo is imbedded in a mealy endosperm. The flowers are wind-pollinated, as in the docks (*Rumex*), where they are pendulous on long slender stalks and have large hairy stigmas, or insect-pollinated, as in *Polygonum* or rhubarb (*Rheum*), where the stigmas are capitate and honey is secreted by glands near the base of the stamens. Insect-pollinated flowers are rendered conspicuous chiefly by their aggregation in large numbers, as for instance in bistort (*Polygonum bistorta*), where the perianth is red and the flowers are crowded in a spike. In buckwheat (*q.v.*, *P. fagopyrum*) the numerous flowers have a white or red perianth and are perfumed, they are dimorphic, *i.e.*, there are two forms of flowers, one with long styles and short stamens, the other with short styles and long stamens. In other cases self-pollination is the rule, as in knot-grass (*P. aviculare*), where the very small, solitary, odourless flowers are very rarely visited by insects and pollinate themselves by the incurring of the three inner stamens on to the styles.

Polygonaceae is mainly a north temperate order. A few genera are tropical *e.g.*, *Coccoloba*, which has 125 species restricted to tropical and sub-tropical America. *Polygonum* has a very wide distribution, spreading from the limits of vegetation in the northern hemisphere to the mountains of tropical Africa and South Africa, through the highlands of tropical Asia to Australia, and in America as far south as Chile. Most of the genera have, however, a limited distribution. In the British Isles, *Polygonum* has 14 species; *Rumex* (12 species) includes the various species of dock (*q.v.*) and sorrel (*R. acetosa*); and *Oxyria digyna*, an alpine plant (mountain sorrel), takes its generic name (*Gr. ὄξυς*, sharp) from the acidity of its leaves. *Rheum* (rhubarb, *q.v.*) is central Asiatic.

In the United States the largest genus is *Eriogonum*, containing about 200 species, all natives of America, and most of them in the western United States. The other prominent genera occurring in America are *Rumex* (docks), and *Polygonum* (knotweeds). *Fagopyrum* (buckwheat) and *Rheum* (rhubarb or pie-plant) also are abundant, but they are natives of the old world. The Mexican genus *Intigonon* is cultivated in the south as an ornamental.

POLYGONAL AND POLYHEDRAL NUMBERS: see FIGURATE NUMBERS.

POLYGONS. A polygonal line, also called a broken line, joining the point A_1 to the point A_n as any finite set of points A_1, A_2, \dots, A_n and the segments $A_1A_2, A_2A_3, \dots, A_{n-1}A_n$. In this and the following definition of a polygon the phrase "a point A_i " means a point associated with the symbol A_i and the phrase "a segment A_iA_j " means the segment whose ends are the points which are the associates of the symbols A_i and A_j , respectively, associated with the symbol A_iA_j . A segment is the set of all points of any (straight) line which are between any two points of that line. Each of the latter points is called an end of the segment. A polygon is any finite set of points A_1A_2, \dots, A_n and segments $A_1A_2, A_2A_3, \dots, A_{n-1}A_n, A_nA_1$; the points A_i and segments $A_iA_{i+1}, A_nA_1, i=1, 2, \dots, n$, are called respectively the vertices and sides of the polygon, similarly for a polygonal line.

The terms polygonal line and polygon are used also with meanings which are different from, although closely related to, those given above. A polygon as defined may have one of two senses assigned to it so that the first end and the second end of each side is specified in such a way that the vertex A_i is either the first end of the side $A_i A_{i+1}$ and the last end of the side $A_{i-1} A_i$, and if $i=1$, A_1 is the first end of $A_1 A_2$, and the second end of $A_n A_1$, or vice versa. A polygon with such an assignment of a sense is called an *oriented* or a *sensed polygon*. In an obvious way an oriented polygonal line is defined. Thus two sensed polygons or polygonal lines are associated with each polygon or polygonal line. In the sequel the phrase the oriented (or sensed) side AB of a sensed polygon indicates that A is the first end of the oriented side AB of that oriented polygon, and B the second. Polygonal lines and polygons according to the first definition are referred to as *unoriented* or *unsensed polygonal lines* and *polygons* respectively. In formulating a third meaning of the terms polygonal line and polygon it should be emphasized that the elements involved in the above definition are points and segments associated with symbols so that an unoriented or oriented polygon is neither a set of points and segments nor a set of points. The word polygonal line is used to signify either certain sets of points and segments or certain sets of points. The distinctions just pointed out although delicate are logically essential and even practically important. For the purpose of this article the single word "polygon" denotes any set of points which consists of the points which are the associates of the symbols A_1, A_2, \dots, A_n and the points which belong to the segments which are the associates of the symbols $A_i A_{i+1}$, $i=1, 2, \dots, n$ and $A_n A_1$ of the first definition; i.e., the definition of an unsensed polygon. Similarly in the case of a polygonal line.

The above definitions are of broad scope and define abstractions which are based on the phenomenon of the motion of a particle from point to point along intermediate rectilinear stretches. Important specializations of these ideas are the so-called *simple polygons* or *polygonal lines* according to any of the definitions given. A simple unoriented polygon is any unoriented polygon which is such that none of its vertices is an end of more than two of its sides and no side of the unoriented polygon contains a vertex or a point which belongs to another side of the unoriented polygon. The definitions of simple unoriented polygonal lines, simple oriented polygonal lines and polygons as well as those of simple polygons and polygonal lines in conformity with the third definition are apparent and consequently are not stated formally. Alternative definitions for the several concepts defined or indicated above may be given; for example a simple polygon may be defined as a finite set of points and segments such that (a) every point of the set is the end of two and only two segments of the set, (b) each end of every segment of the set is a point of the set, (c) no segment of the set contains a point of the set or a point of another segment of the set and (d) no (proper) subset of the given set satisfies (a), (b) and (c). It is easy to show that this definition is equivalent to the one indicated in introducing the third formulation of the idea of a polygon and it is valuable in that it admits of immediate generalization to the idea of a polyhedron in space.

Place of Polygons in Mathematics.—The theory of polygons as a special chapter in mathematics is chiefly concerned with the classification of unoriented and oriented polygons all of whose elements,—that is, vertices and sides,—are in the same plane. The corresponding question for space concepts polyhedrons and is taken up in the article on SOLIDS, GEOMETRIC. Polygons whose elements are not in one plane have not as yet formed the subject of any interesting theory. Such polygons, as well as plane polygons, however, serve as important aids, as in the study of continuous curves in general. This is largely because of the fact that any continuous arc contains the vertices of a polygonal line, the length of whose sides are all less than any pre-assigned positive number, and which is simple if the arc is simple. In particular, the length of an arc of a curve is defined by means of the lengths of the inscribed polygonal lines,—that is, polygonal lines which join the ends of the arc and whose vertices are on the arc and have an order which conforms to one of the two senses

along the arc. In the geometry of the Euclidean plane, plane polygons,—that is, those having all of their points in one plane,—take on an added significance because of the fact that the Euclidean plane is separated into two regions by any simple polygon that is contained in it. This is a consequence of the basic fact that a line separates the Euclidean plane. Unless it is stated otherwise it is understood that in the following all configurations are in the Euclidean plane. A *region* is a set of points such that any point of the set is the centre of a circle which has only points of the set in its interior and such that the set is not composed of two sets having the latter property and also having no points in common. It follows easily that any two points of a region are joined by a simple polygonal line which is contained in the region. A precise statement of the important fact mentioned above is that if P is any simple plane polygon, then the plane is composed of P and two regions which have no points in common with each other or with P . One of these regions is of infinite extent and the other is not. A region such as the latter is referred to as a *polygonal region* and also as the *interior* of the polygon concerned and the latter is called the *boundary* of the polygonal region. Every circle which has a point of the boundary of the polygonal region as centre contains points of the region and any point which is such that any circle having it as centre contains points which belong to the region and also points which do not is a point of the boundary of the region. This property of the boundary of any polygonal region is used as the defining property of the boundary of a region in general. As a further consequence should be mentioned the fact that any polygonal region plus its boundary is composed of a finite number of triangles and their interiors, which have no points in common, and the vertices of the triangles are vertices of the bounding polygon. A region which is not a polygonal region is, however, approximated by polygonal regions according to the following theorem: If Σ is any region, then there exists a sequence of polygonal regions $\Sigma_1, \Sigma_2, \dots, \Sigma_n, \dots$ such that (a) Σ_n and its boundary is contained in Σ and also in Σ_{n+1} for all (positive integral) values of n and (b) each point of Σ is contained in all but a finite number of the polygonal regions Σ_n . This theorem is easily proved by using as the polygonal regions regions which are composed of congruent squares which are formed by two sets of parallel lines, the lines of each set being equally spaced and intersecting orthogonally those of the other set. These acts indicate the importance of polygonal lines and polygons in the study of more general configurations.

THE THEORY OF PLANE POLYGONS

The Interior, Exterior and Peripheral Angles of a Plane Polygon.—We now proceed to the special theory of plane polygons. As remarked above, this theory concerns itself largely with unoriented and oriented polygons. In the case of a simple polygon the meaning of "an interior angle of a polygon" is immediate in virtue of the theorem concerning the separation of the plane by the polygon. This meaning leads to an interesting generalization in the case of an oriented polygon. In proceeding to this generalization and to related ideas it should be stated that all of the terms used are not defined with the mathematical completeness that would be possible with a greater allowance of space, but it has been aimed at least to indicate clearly the way to that completeness. Now it can be proved that if P is a simple oriented polygon and A any vertex of P then for the positive (counter-clockwise) rotation of any side AB of P about its first end A , in accordance with the sense of P , which transforms the side AB into the other side of P having A as an end and which has a magnitude not exceeding 2π radians, then the points on the intermediate positions of AB which are within a certain distance of A are all in the interior of the polygon determined by P if the sense of P is the same as that of the rotation and all in the exterior in the contrary case. (Note that senses of oriented polygons are compared only in the case of simple oriented polygons.) Accordingly the *interior angle at any vertex A_i* of any oriented polygon P is defined as the positive angle (rotation) which has A_i as its vertex and whose initial side contains the side of P which has A_i

as its first end, say the side A_1A_{t+1} , whose terminal side contains the side with the ends A_1 and A_{t-1} , if $t \neq 1$, and A_n , if $t = 1$, and whose magnitude does not exceed 2π . (See fig. 1.)

Further if A_1 is any vertex of an oriented polygon P and the first end of the oriented side A_1A_{t+1} of P then there is a rotation about A_1 of the half-line having A_1 as its initial point and having the same direction as the oriented side A_1A_{t+1} ($t-1 \equiv n$ if $t=1$),

FIG. 1—CONTINUOUS DEFORMATION OF AN ORIENTED POLYGON, WITH FIVE VERTICES

that is the half-line of the line through A_{t-1} and A_t , which has A_1 as its initial point and which does not contain A_{t-1} , into the half-line which contains the side A_1A_{t+1} which has a magnitude greater than $-\pi$ and less than or equal to π and there is another such rotation which is positive and has a magnitude not exceeding 2π . The former angle (rotation) is called the *exterior angle* and the latter the *peripheral angle* of the oriented polygon P at the vertex A_1 . If $\alpha_1, \beta_1, \gamma_1$ are, respectively the magnitudes of the interior, exterior and peripheral angles of the oriented polygon P at the vertex A_1 , then $\alpha_1 + \beta_1 = \pi$ and $\alpha_1 + \gamma_1 = \pi$ or 3π according as α_1 is or is not less than π . If α_1 is less than π then γ_1 is and conversely. If the sum of all the β_i is set equal to $2a\pi$ and the sum of all the γ_i to $2a'\pi$ then a and a' are integers or zero as a simple consideration shows and $a' - a$ is the number of interior angles of P whose magnitudes are greater than or equal to π . If P' and P'' are two oriented polygons which differ only in orientation and if $\alpha'_1, \beta'_1, \gamma'_1$ and $\alpha''_1, \beta''_1, \gamma''_1$ are respectively the magnitudes of the interior, exterior and peripheral angles of P' and P'' at the vertex A_1 , then $\alpha'_1 + \alpha''_1 = 2\pi$, $\beta'_1 + \beta''_1 = 0$ and $\gamma'_1 + \gamma''_1 = 2\pi$. Hence the value of a' for P'' is the negative of its value for P' while the value of a' for P'' is the number of vertices of P' (or P'') minus the value of a' for P' .

Classification of Plane Polygons.—In the classification of oriented polygons the numbers a and a' have been used to define the so-called types of such polygons. It is obvious how they may be used in the classification of unoriented polygons. There exist oriented polygons of any number n of vertices for which the value of a is any number whose absolute value does not exceed $\frac{1}{2}(n-1)$ except that for a triangle a cannot be zero. A more detailed scheme of classification is according to the values of a and $a' = a - a$. If all of the interior angles of an oriented polygon have magnitudes which do not exceed π then the polygon is called a *convex oriented polygon*. The unoriented polygon P is convex if and only if P with a sense assigned to it is convex. Both of these definitions are in conformity with the important notions of a *convex simple polygon* and a *convex polygonal region*. A *convex region* is a region such that all of the points of any segment whose ends belong to the region belong to the region also. A simple polygon is said to be convex if it is the boundary of a convex region, which is then a convex polygonal region. As theorems we have: A line which does not contain a side of a convex simple polygon contains not more than two points of the polygon and conversely. Also, no point of a convex simple polygon is on a particular one of the two sides of the line which contains any side of the polygon and conversely.

Another method of classification of unoriented and oriented polygons uses the notion of the continuous deformation of such polygons. Any one of two unoriented polygons with the vertices A_1, A_2, \dots, A_n and B_1, B_2, \dots, B_n respectively is deformable continuously into the other so that the vertex A_i corresponds to the vertex B_i and the side A_1A_{t+1} to the side B_1B_{t+1} . To obtain subclasses of unoriented polygons continuous deformations of such polygons, which satisfy any or all of the following conditions, are used: (1) no intermediate polygon of the deformation has two consecutive sides which lie in the same line and which have no points in common; (2) neither of two consecutive sides of any intermediate polygon of the deformation is contained in the other, and (3) no point is common to more than two sides of

any intermediate polygon of the deformation. In the case of oriented polygons it is also required that sense be preserved by the deformation. Two oriented polygons that are transformable one into the other by a continuous deformation satisfying the first condition have the same value for a . If instead of the first condition the second is satisfied the oriented polygons have the same value for a' . If the deformation satisfies both the first and second conditions then the two oriented polygons are related so that if the magnitudes of one of two corresponding interior angles is less than π then the same is true of the other. Corresponding results for unoriented polygons follow easily. An interesting classification of unoriented polygons which satisfy the conditions on the intermediate polygons of the deformations satisfying all three conditions and which, in addition, have no vertex as an end of more than two sides and no side containing a vertex or a point belonging to more than two sides is that in which any unoriented polygon in one class is deformable into any other or into the symmetric image of any other in that class by a continuous deformation satisfying all three of the above conditions. For unoriented polygons of 4, 5 and 6 vertices there are respectively 3, 11 and 70 classes under this classification.

Non-metrical and Metrical Theories. Regular Polygons.

Area of Polygons.—It should be pointed out that the above theory of the classification of unoriented and oriented polygons holds without essential modification in a more general plane than the Euclidean for only the order relations of the Euclidean plane are essential. Between this theory and the corresponding theory in the projective plane there are, because of the different kinds of linear order, some essential differences, but both theories are non-metrical. By making use of the metric properties of the Euclidean plane the consideration of regular polygons, oriented or not, becomes possible, also the question of the area of polygonal regions arises. An unoriented polygon is *regular* if any side is congruent to any other side and any angle of the polygon, i.e., the figure consisting of a vertex and the two consecutive sides having that vertex as an end, congruent to any other "angle" of the polygon. The regular polygons are convex and there exists a circle circumscribed about and another inscribed in every regular polygon. Those regular polygons that are not simple also are called *star polygons*. If π points which are equally spaced on the circumference of a circle and numbered in order along that circumference are joined by segments so that the t -th point is joined to the $(s+t-d)$ -th point, where d is a fixed positive integer, then the polygon resulting is a regular polygon for which the value of a , defined above, is d . Thus the number of "types" of regular polygons of n vertices is half of the number of positive integers which are less than and prime to n . Other kinds of regular polygons have been studied with particular reference to their classification along the lines explained above. For instance, there are the polygons which have the property that the figure composed of any vertex and the two sides of the polygon which have that vertex as an end is congruent to any other such figure and also the polygons which are such that the figure consisting of any side and two adjacent angles of the polygon is congruent to any other such figure. These polygons have an even number of vertices and a circle is circumscribable about any of those of the former kind and inscribable in any of those of the latter.

FIG. 2—DEFORMATION OF A POLYGON OF FOUR VERTICES INTO THREE TYPES

Assuming the fact that the area of any plane simple polygon or rather polygonal region is the sum of the areas of the triangles of any finite set of triangles which have no interior points in common and which are such that every point of the polygonal region belongs to a triangle of the set or to the interior of one and every point of any triangle of the set or of the interior of any belongs to the polygonal region or its boundary the notion of the area of any plane unoriented or oriented polygon is approached. In the case of an unoriented or oriented polygon in general there is no region uniquely determined as in the case of simple polygons. In

the following only the case of oriented polygons is considered for that essentially covers the case of unoriented polygons. If the area of a triangle according to the usual meaning is σ then the area of that triangle with a sense assigned to it is defined as σ or $-\sigma$ according as that sense is positive or negative, $\pm\sigma$, the same or not the same as the counterclockwise sense along the circumference of a circle. Using the symbol $A_1A_2 \dots A_n$ to denote

FIG. 3.—DEFORMATION OF A POLYGON OF FIVE VERTICES INTO 11 DIFFERENT TYPES

the oriented polygon with the vertices A_1, A_2, \dots, A_n and the sensed sides A_1A_2, \dots the area of the oriented polygon $A_1A_2 \dots A_n$ is defined as the sum of the areas of the oriented triangles $OA_1A_2, OA_2A_3, \dots, OA_{n-1}A_n$ where O is any point of the plane. It is, of course, proved that the value of the area thus defined does not depend on the position of O and that if $A_1A_2 \dots A_n$ is simple, this definition agrees with the area of a simple polygon according to the fundamental definition. An oriented polygon P determines a finite number of polygonal regions in its plane which have no points in common and whose boundaries are composed of points belonging to P . One and only one of these regions is of infinite extent. Now the following interesting facts pertain: let the regions, or cells, of finite extent be denoted respectively by S_1, S_2, \dots, S_i , and let the area of the cell S_i according to the fundamental definition of the area of a polygonal region be σ_i so that σ_i is a positive number; then there exists a set of numbers c_1, c_2, \dots, c_k which are either integers or zero such that the area of the oriented polygon P is $c_1\sigma_1 + c_2\sigma_2 + \dots + c_k\sigma_k$. Further, c_i is the number of complete positive revolutions minus the number of complete negative revolutions made by the radius vector, having any point O of S_i as its initial point, as its terminal point describes once the oriented polygon P in the assigned sense; c_i is called the coefficient of the cell S_i . (See ANALYSIS SITUS.)

BRUCHOPOLYGY.—M. Bruckner, *Vielecke und Vielfache* (Leipzig, 1902); H. G. Forder, *The Foundations of Euclidean Geometry*, ch. 10, 11 (London, 1927); E. Steinitz, *Encyklopädie der mathematischen Wissenschaften*, Bd. III, heft 9 (Leipzig, 1922); O. Veblen and J. W. Young, *Projective Geometry*, vol. II, ch. ix (1918); C. Wiener, *Über Vielecke und Vielfache* (Leipzig, 1864). (G. A. P.; X.)

POLYGYNY, the system under which a man is married to several women at the same time (Gr. πολύς , many, and $\gammaυνή$, woman), popularly called polygamy ($\gammaάμος$, marriage), which derivatively also includes the practice of polyandry. Polygyny is nowhere the exclusive form of marriage, and among most peoples who practise it the large majority of men live in monogamy. It may be modified in a monogamous direction both from the social and the sexual point of view. Frequently one of the wives, generally the one first married, holds a higher position than the rest or is regarded as the principal wife. In some cases this position implies certain sexual privileges; but more often we are told that it is the custom for the husband to cohabit with wives in turn, or that this is actually required of him. Another matter

is how far theory and practice coincide. We have reason to suspect that one of the wives is for a time the favourite.

Lower Culture Groups.—Among the uncivilized races polygyny does not seem to be practised on a large scale by any of the lower hunters and food collectors, except some Australian and Bushman tribes, nor by any incipient agriculturists, at least among those of the lower type. On the other hand, a considerable number of these low-hunting and slightly agricultural tribes—such as some of the South American Indians, the aboriginal tribes of the Malay peninsula, most of the Andaman Islanders, the Veddas of Ceylon, certain tribes in the Malay archipelago, most of the Negritos of the Philippine Islands and some at least of the central African pygmies—are represented as strictly monogamous. Among the higher hunters polygyny is more frequent, although in the majority of their tribes it is practised only occasionally, and exclusive monogamy is rare, though perhaps not unknown. Among pastoral peoples there seems to be no one who can be regarded as strictly monogamous, and both among them and the higher agriculturists polygyny is undoubtedly more frequent than among the hunters and incipient agriculturists, although cases of regular monogamy are more frequent among the higher agriculturists than among the higher hunters. The cases in which polygyny is represented as "general" are comparatively much more numerous among African than among non-African pastoral peoples and higher agriculturists. Polygyny is at its height in Africa, both in point of frequency and in number of wives. King Mtesa of Uganda and the king of Loango are said to have had 7,000 wives. This is apparently the high-water mark of polygyny anywhere.

Archaic Civilizations.—Polygyny, or a sort of concubinage hardly distinguishable from genuine polygyny, is found among most peoples of archaic civilization. In China there are, or have been, besides the legal principal wife, so-called wives "by courtesy" or lawful concubines. In Japan concubinage of the Chinese type existed as a legal institution until 1880. In ancient Egypt polygyny seems to have been permitted but to have been unusual, except in the case of kings. The Babylonian code of Hammurabi assumes that marriage shall be monogamous; yet "if a man has married a wife and a sickness has seized her," he may take a second wife; and if she remained childless he might take a concubine. Among the Hebrews a man could in any circumstances have a plurality of wives, and there was no difference in the legal status of different wives, nor was there any limit to the number of wives a man might take. In Arabia Mohammed ordained that a man's legal wives should be not more than four. Polygyny has been permitted among many of the Indo-European peoples—among ancient Slavs and Teutons, the ancient Irish and the Vedic Indians—though it seems to have been as a rule confined to kings or chiefs or nobles. None of the Hindu lawbooks restricts the number of wives a man is allowed to marry, yet some preference is often shown for monogamy, and at the present day most castes object to their members having more than one wife, except for some cogent reason. On the other hand, there can be little doubt that monogamy was the only recognized form of marriage in Greece, concubinage existed in Athens, but it was well distinguished from marriage, conferring no rights on the concubine. Roman marriage was strictly monogamous; liaisons between married men and mistresses were not uncommon by the close of the republic, but such a relation was not considered lawful concubinage in aftertime.

Christian and Modern Times.—Polygyny has been found even in Christian Europe. No obstacle was put in the way of its practice by kings in countries where it had occurred in the times of paganism. In the middle of the 6th century Diarmait, king of Ireland, had two queens and two concubines. Polygyny was frequently practised by the Merovingian kings. Charlemagne had two wives and many concubines; and one of his laws seems to imply that polygyny was not unknown even among priests. In later times Philip of Hesse and Frederick William II of Prussia contracted bigamous marriages with the sanction of the Lutheran clergy. In 1650, soon after the peace of Westphalia, when the population had been greatly reduced by the Thirty Years' War, the Frankish *Kreisstag* at Nuremberg passed the resolution that

thenceforth every man should be allowed to marry two women. The Anabaptists and the Mormons have advocated polygyny with much religious fervour.

Causes.—One cause of polygyny is an excess of marriageable women, we may safely say that whenever there is a marked and more or less permanent majority of women in a savage tribe polygyny is allowed. But while the existence of available women makes polygyny possible, the direct cause of it is generally the man's desire to have more than one wife. There are various reasons for this desire. Among many of the simpler peoples the husband has to abstain from his wife not only for a certain time every month, but during her pregnancy, or at least during the latter stage of it, and after child-birth until the child is weaned, which often means an abstinence lasting for a couple of years or more. Other causes of polygyny are the attraction which female youth and beauty exercise upon the men, the latter's taste for variety their desire for offspring—which is one of the principal causes of polygyny in the East—and the fact that polygyny contributes to a man's material comfort or increases his wealth, and thereby also his social importance and authority, through the labour of his wives. The usefulness of wives as labourers partly accounts for the increasing practice of polygyny at the higher grades of economic culture. But it should also be noticed that economic progress leads to a more unequal distribution of wealth, and this, combined with the necessity of paying a bride price the amount of which is more or less influenced by the economic conditions, makes it possible for certain men to acquire several wives while others can acquire none at all.

POLYMERIZATION: see SOLIDS, GEOMETRIC.

POLYMERIZATION, in chemistry, was originally considered to be any process in which two or more molecules of the same substance unite to give a molecule (polymer) with the same percentage composition as the original substance (monomer), but with a molecular weight which is an integral multiple of the original molecular weight. When the monomer and the polymer are so easily interconvertible that their isolation and chemical distinction are difficult (as in water), the process is usually considered to be association (*q.v.*). The term "polymerization" now applies when the monomer and polymer are easily isolated and distinguished. The term is also commonly applied to the making of polymers which do not conform to the original definition (see below).

Many organic materials which contain double or triple bonds in their structural formulas undergo addition polymerization on standing or heating, the original volatile materials becoming less volatile liquids or solids with the same elementary analyses (see *CHEMISTRY Organic Chemistry* for many terms used here, particularly olefins, acetylenes and diolefins). Some of these polymers contain only two or three monomer units, some contain many, and some monomers yield more than one kind of polymer. Some polymers can be converted back to monomers by heating (see *CYANAMIDE*, *CYANIC ACID* AND *CYANATES*; *FORMALDEHYDE*, *TERPENES*). Phosphonitride chloride, $P=NCN$, is an inorganic compound yielding several polymers.

The polymerization of ethylene derivatives (olefins) is of great technical importance and illustrates addition polymerization. For instance, styrene (phenylethylene, $C_6H_5-CH=CH_2$) is a colourless liquid with an aromatic odour. On standing for several weeks at room temperature or for a few days at $100^\circ C$, the pure liquid polymerizes, becoming at first an increasingly viscous solution of polymer in monomer, and finally a clear, odourless, glassy solid. The product is a mixture of polymer molecules of the formula $(C_8H_8)_n$, where n has a wide range of values and averages several thousand. When the monomer is warmed with a fraction of 1% of

an initiator such as benzoyl peroxide, $C_6H_5-CO-O-CO-C_6H_5$, a similar polymer is formed, but in a few minutes or hours instead of days or weeks. These processes are chain reactions, starting when styrene is activated thermally, or when the initiator decomposes, to give electrically neutral fragments of molecules with free or unsatisfied valences (free radicals with trivalent carbon atoms). Such a fragment, $R\cdot$, adds easily to the double bond in the monomer

forming a larger molecule with the free valence now on the styrene unit. This new free radical adds to another double bond, and so on, so that many monomer units become linked together. Thousands of steps in a single reaction chain may occur in a second, the reaction ending when two radicals interact and mutually satisfy their free valences. Completed polymer molecules thus appear as soon as the polymerization starts. Large polymer molecules containing initiator fragments have nearly, but not exactly, the percentage composition of the monomers. The initiator is frequently called a catalyst (see *CATALYSIS*), although strictly it is not, since it is consumed during its action. To avoid mechanical difficulties in preparing and handling large masses of hard or viscous polymer, technical preparations are frequently carried out in emulsion or suspension in water. The polymer is then obtained as a synthetic latex or as beads.

Some metal halides (aluminum or stannic chlorides, boron trifluoride), strong acids (sulphuric), alkali metals and very strong bases (sodamide) also cause polymerization of olefins, but these initiators are ineffective in the presence of water. Such polymerizations are also chain reactions, but the growing molecules are ions or ion pairs instead of neutral radicals.

When a mixture of two monomers is subjected to polymerization, the product may contain both monomers in each polymer molecule (*i.e.*, copolymerization of the two monomers yields a copolymer) or it may contain only one kind of monomer in each polymer molecule, depending on the monomers and the initiator. Many commercial polymers are actually copolymers, a wider range of properties being possible than with single monomers. GR-S, principal synthetic rubber in the United States, is a copolymer of butadiene with 20%–25% of styrene, and is made in aqueous emulsion. The "cold rubber" made at about $5^\circ C$. proved to be generally superior to that made at 50° . Butyl rubber is made by polymerizing isobutylene, $(CH_3)_2C=CH_2$, with a small percentage of isoprene at about $-100^\circ C$. with a metal halide catalyst. Polymers of methyl methacrylate, $H_2C=C(CH_3)-CO-O-CH_3$, which yield sheets and formed articles of unusual clarity, polymers and copolymers of vinyl chloride, $H_2C=CHCl$, and vinyl acetate, $H_2C=CH-O-CO-CH_3$, which have wide use in films, coatings and mouldings, copolymers of acrylonitrile, $H_2C=CH-CN$, which are employed in synthetic fibres and in oil-resistant rubber; and polymers of chloroprene, $H_2C=CCl-CH=CH_2$, which are also oil-resistant rubbers, are important products of addition polymerization.

Condensation polymerization is the process of making products of high molecular weight, commonly called polymers, with the elimination of a small, easily removed molecule (often water) for each step in the process. Thus, the alcohol group of one hydroxy-acid molecule, $HO-(CH_2)_x-CO-OH$, reacts with the acid group of another to give $HO-(CH_2)_x-CO-O-(CH_2)_y-CO-OH + H_2O$, providing that x does not equal 3 or 4 (see *ESTERS*; also *CHEMISTRY Organic Chemistry*). This first product still contains free alcohol and acid groups and may react further to give molecules containing more and more units, joined end to end. After y such steps, $y + 1$ molecules have condensed with the elimination of y molecules of water. The product therefore differs in composition from the monomer but its physical properties are sufficiently like those of some addition polymers that it is commonly called a polymer. This condensation polymerization is carried to an advanced stage only as water is removed by heating. In further contrast to addition polymerization, only products of low molecular weight are formed at the beginning of the reaction and their growth continues slowly throughout the condensation. An important condensation polymer is the polyamide (see

AMIDES), a nylon, containing the repeating unit $-\text{CO}-(\text{CH}_2)_6-\text{CO}-\text{NH}-(\text{CH}_2)_4-\text{NH}-$, made by heating adipic acid, $\text{HO}-\text{CO}-(\text{CH}_2)_6-\text{CO}-\text{OH}$, and hexamethylenediamine, $\text{H}_2\text{N}-(\text{CH}_2)_6-\text{NH}_2$, at about 200°C

In the above examples, each monomer molecule contains two sites of reaction and the polymer molecules are long chains. Such polymers soften on heating and dissolve in solvents. If a monomer contains more than two sites of reaction, the chains may branch and combine into networks, yielding products resistant to heat and solvents. Condensation polymers of this type are formed, for example, from phthalic anhydride and glycerol, phenol and formaldehyde, or urea and formaldehyde. They are widely used in surface coatings and moulded plastic products (see RESINS *Synthetic Resins*)

(FR. R. M.)

POLYMORPHISM. Many chemical substances, elements as well as compounds, crystallize in two or more distinct atomic arrangements which are differentiated by their X-ray diffraction patterns, outward crystal form, optical properties, energy content, volume, etc., and as such, are separate crystalline phases of the substance, according to the definition laid down by J. W. Gibbs (1876). The name "polymorphism" was applied to this property by E. Mitscherlich (1823), who discovered it in sodium phosphate and sulphur. Another term, "allotropy," attributable to J. Berzelius (1841), was proposed as a name for the supposed different conditions of the same element, both in the pure state and in compounds of which the element forms a part. Subsequent usage tended to confine the term to elements (W. Ostwald, 1893), and included such forms as gaseous oxygen and ozone, the mobile and viscous forms of sulphur, the different forms of phosphorus and the diamond and graphite forms of carbon. In the broadest sense, allotropy was applied by A. Smits (1911) to compounds in studies of "inner equilibria" prevailing therein between different molecular species. All cases of allotropy in the crystalline state are merely examples of polymorphism, and are best described as such. A polymorphic substance may be described as dimorphic, tri-

morphic, etc., according to the number of distinct crystalline forms

Polymorphic substances may also be distinguished according to whether or not two given forms are reversibly transformable one into the other. When the transformation is reversible, the change is said to be enantiotropic. If it is found to be unidirectional only under all conditions investigated thus far, it is said to be monotropic. Two phases of one substance in equilibrium form a univariant system according to the phase rule, this means that if pressure and temperature are chosen as the external variables, the equilibrium temperature will depend upon the pressure, the composition being constant. The equilibrium temperature at constant pressure is known as the transition or inversion point. For example, rhombic sulphur is in equilibrium with monoclinic sulphur at 95.6°C , 1 atm, and at 129.9°C , 845 atm. The variation of the transition temperature with the pressure is expressed quantitatively by the Clapeyron equation in the form $dT/dp = T(v_2 - v_1)/L$ where T is the temperature on the Kelvin scale, p the pressure, L the latent heat absorbed and $v_2 - v_1$ the difference in volume of the high- and low-temperature form, respectively, all per unit mass dT/dp was measured for numerous enantiotropic transitions by G. Tammann, P. W. Bridgman and others. Since $v_2 - v_1$ is usually small in comparison with L/T , high pressures are required to produce appreciable changes in the transition temperature, for sulphur in the above example, the average $dT/dp = 0.034^\circ\text{C}$ per atmosphere. Other examples are low to high quartz, 0.021°C , red to yellow HgI_2 , 0.0016°C . Three phases of one substance in equilibrium form an invariant system, this means that the phases can coexist at some one constant pressure and temperature characteristic of the phases present. This invariant point is named the triple point. In polymorphism two of the phases must be different crystalline forms of the substance, the third phase may be another crystal form, or liquid or vapour. For sulphur the triple point rhombic-monoclinic-vapour is 95.6°C , (approx.), 0.0003 atm, rhombic-monoclinic-liquid, 153.7°C , 1,400 atm. For water, which has seven crystalline phases, the triple point ice I-ice II-ice III is at -34.3°C , 2,100 atm (see ICE).

A polymorphic substance, when mixed with one or more other substances and brought to equilibrium, may have its transition point changed. Both experimental evidence and deductions from the phase rule indicate that this occurs when the polymorph and the added substance form solid solution. If the polymorph crystallizes pure from the mixture or solution, the transition point remains unaltered. Thus, NH_4NO_3 , which crystallizes pure from its aqueous solution, is found to invert at 32° , 84° and 125°C , whether alone or in the presence of its aqueous solution. KNO_3 , on the other hand, forms solid solutions with NH_4NO_3 , and equilibrium mixtures of the two invert at temperatures which depend on the composition of the system. Specifically, e.g., 20% KNO_3 added to NH_4NO_3 lowers the 32° transition to near 0°C .

The enantiotropic transformations considered above are in many respects analogous to melting or freezing, with one important difference. In melting it is rarely observed that a crystal can be superheated above its melting

FIG. 1.—PRESSURE-TEMPERATURE PHASE DIAGRAM FOR SILICA. SOLID LINES REPRESENT TRANSITIONS OF PHASES STABLE IN THE RESPECTIVE ADJOINING REGIONS. BROKEN LINES REPRESENT TRANSITIONS OF METASTABLE PHASES. TRIDYMITE AND CRISTOBALITE IN THE REGION OF THEIR ALPHA-BETA TRANSITIONS ARE EACH METASTABLE WITH RESPECT TO ALPHA QUARTZ, WHICH IS HERE THE STABLE PHASE.

point although undercooling on freezing is common. Polymorphic transitions may be both superheated and undercooled, the width of the band of indifference (hysteresis band) varies from a few degrees for prompt transitions to unknown values for very sluggish ones. Transitions in which only minor changes of crystal symmetry occur are often prompt, while those involving marked alterations of structure are usually more or less sluggish. Both varieties of behaviour may be found in the same chemical substance, as in silica (*qv*). See fig. 1. The three main varieties of silica are quartz, tridymite and cristobalite. These differ considerably in their crystal structures, and are mutually transformed only with great difficulty, quartz to tridymite at 867°C and tridymite to cristobalite at $1,470^{\circ}\text{C}$, at the pressure of one atmosphere. The sluggishness of these transformations is evidenced by the fact that these varieties of silica have been found in co-existence in certain volcanic rocks for geologic ages. On the other hand, there occur one or more relatively rapid transitions between high- and low-temperature forms of each of the main varieties, accompanied by only slight changes in crystal structures, namely, in quartz at 573°C , in tridymite at 118° , 103° and 230°C and in cristobalite between 200° and 275°C . In the slow transformation of quartz to tridymite or to cristobalite, catastrophic changes in the structure occur which involve the breaking of Si-O-Si bonds, whereas only distortions of structure occur in the rapid transitions of the low- to high-temperature forms in quartz, tridymite or cristobalite.

The enantiotropic transformations may be contrasted with the monotropic transformations, for which no transition temperature had been found experimentally at mid-20th century. The classification is not particularly exact, inasmuch as it is usually based not on the knowledge of the actual stabilities of the phases but rather on empirical findings, usually at atmospheric pressure only. The tendency to transform may be held in abeyance by the same energy barriers that are responsible for the metastable existence of such enantiotropic forms as cristobalite at ordinary temperature. Many cases of monotropism at ordinary pressure occur among organic compounds, as in chloroacetic acid, which can crystallize in three different forms with melting points at 50.2° , 56.2° and 61.3°C , the two lower melting forms being unstable with respect to the highest melting form. An instance of apparent monotropism is offered by calcium carbonate, which is found in nature as the stable calcite (*qv*) and as aragonite, which is unstable with respect to calcite at ordinary and higher temperatures. The transformation aragonite to calcite at these temperatures is truly unidirectional. A thermodynamic study of the stabilities of the two indicates, however, that below -60°C aragonite becomes the stable form. At higher temperatures, the complex aragonite structure, although unstable, inverts only slowly to the simpler structure of calcite. Both aragonite and calcite have been found together in certain fossils. The influence of structure on transformability is shown even more strikingly in diamond and graphite, two forms of carbon (fig. 2). Diamond, the less stable form,

has a very rigid cubic structure, with each carbon atom joined to four others by bonds of equal strength, whereas the rhombohedral graphite has one weak bond and three much stronger ones. These give it its layer lattice and lubricating properties. The two lattices have nearly the same energies of cohesion, about $170,000\text{ cal per mole}$, which differ by only 500 cal per mole , the difference is too small to provide the energy of activation for the necessary rearrangement in the strengths of the bonds, and there is no evident tendency to transform at ordinary temperatures. From measurements made at the national bureau of standards, it appears that high pressures and low temperatures increase the thermodynamic stability of diamond, very great pressures would, however, be required to produce artificial diamonds at temperatures high enough for the rate of transformation to become appreciable (much more than $50,000\text{ atm}$ at $2,000^{\circ}\text{C}$).

The occurrence of polymorphism and the formation of metastable modifications had not yet been satisfactorily explained in detail at mid-20th century. Qualitatively, the energy change in the transition of one form to another (i.e., the heat of transition) is much smaller than the energy of formation of the individual lattices from the vapour. A number of atomic arrangements of nearly the same energy may be possible for a given substance such that different lattices in turn become the more stable at different temperatures. The exact calculations are difficult, and only the lattice energies of the simplest crystals have been calculated. The various possible lattices of a substance may differ in the degree of order of arrangement of the atoms, the more symmetrical lattices, such as the cubic, may be considered as less highly ordered than the less symmetrical, such as the monoclinic or triclinic. It may be noted that the less highly ordered lattices tend to occur as stable phases at high temperatures where the disordering action of thermal vibrations is more violent. They often tend also to crystallize first from melts, from solutions or from the vapour, even though other forms may be more stable. Thus KNO_3 crystallizes from solution in rhombohedra and only later inverts to the more complex orthorhombic stable form, silica almost invariably crystallizes from dry silicate melts as cubic cristobalite rather than as the more complex quartz. Such examples indicate the trend, but apparently there are many exceptions, and little can be said about cases where all the modifications have complex structures. The problem of polymorphism is further complicated by the occurrence of lattices with defects in the atomic arrangement. In the high-temperature forms of AgI , Ag_2S , Ag_2HgI_4 and certain related compounds, some or all of the metal ions are mobile in a still rigid anion lattice, whereas in the low-temperature forms of such substances all the ions are in ordered positions. In heating some alloys, an ordered arrangement of the metal atoms inverts to a random one (Cu_3Au , CuZn , AgZn), and in some other substances, certain radicals or whole molecules change from an ordered orientation to a random one (NH_4Cl , CH_4 , NH_4NO_3 , NaNO_3 , HCl). A still further type of disordering is that suffered by quartz on changing from the low- to the high-temperature form, where bent Si-O-Si bonds are straightened. In such cases the final (abrupt) transition is often preceded by a gradual change in structure, volume, specific heat and other properties, extending over many degrees, as the temperature is raised.

Liquid crystals, turbid, viscous, structure possessing phases intermediate between true crystals and true liquids of some long-chain organic compounds, invert promptly to true crystals with a small heat of transition and a small volume change. About 250 examples are known.

Liquid phase transformations, as in sulphur or helium, may be mentioned as examples not of polymorphism but of allotropy in the broader sense. There is no sharp phase transition, but rather a gradual transformation evidenced by a change in physical properties of the liquid over a narrow range in temperature.

POLYNESIA, the easternmost of the three main divisions of the island groups of the South Pacific, the others being Melanesia and Micronesia (qqv). It includes the numerous groups and small islands situated south of the equator and falling roughly between 170° E and 110° W long. The two islands of New Zealand are the largest and most important homelands of the Polynesians, other groups being the Hawaiian (U. S.), Society and Marquesas (French), Tonga or Friendly Islands (British) and Samoa (British and U. S.). For an account of the structure, geology, climate, flora and fauna, etc., see PACIFIC ISLANDS.

Ethnology.—The Polynesians are a Caucasian people, in contrast to the Negroid Melanesians, their island neighbours to the west, with whom they have intermingled to some extent. They are scattered over the widest expanse of free ocean in the globe, there are so few bits of land between Hawaii and New Zealand, between Easter Island and Tonga, that navigators have crossed this wide body of water without seeing a trace of land. Brown in colour with black hair, tall in stature, governed by chiefs in hereditary line through the father (in contrast to the matrilineal Melanesians), the Polynesians have been warlike and adventurous in their history, while at the same time responsive to foreign influence. The origin of this Pacific island race has fascinated and perplexed students of ethnology, anthropology and archaeology. Only a people with considerable skill in navigation could have reached these islands, yet they have maintained through centuries a very primitive form of economy without a trace of commercial intercourse or money. The preponderance of scientific opinion is that the Polynesians migrated from Asia, not from the American continent. The absence of any trace, among the Polynesians of the religions of the east indicates that the migration took place at a very early period. It seems probable that at some dim prehistoric time they practised a primitive form of "island hopping," moving from one new place of settlement to another in the large canoes which they are traditionally expert in operating until they found their present home in the eastern part of Oceania. There seems to be some reason to believe that Java was the home of these migrants for a time and that they were forced by Malayian invaders to seek a refuge farther east.

Traditions are still retained of a mythical land of the Polynesian forefathers, called Hawaiki (which can be linguistically connected with the word Java as we know it to-day), to which the souls of the dead return. Moreover, the peoples of all the important islands place to the west the locality whence the departed souls commence their journey. Research among the Nagas of Assam, and archaeological research by the French Colonial authorities in Cambodia indicated that there is a linking up with the immigrants, particularly with the Nagas, who apart from their stoneworking, practise many Polynesian customs. The massive stone ruins at Ponape in the Carolines (see MICRONESIA), which are a mystery in their own right, may indicate a stage in the long journey of the Polynesians over thousands of miles of ocean to their present homelands.

Physical Characteristics.—The Polynesians, with their simple outdoor life, often develop fine bodies and are almost always expert swimmers. They are taller than the Melanesians (except for the natives of Fiji, where there is some intermixture of the two races), with long, black hair and black, expressive eyes. Tattooing is much in vogue. The Polynesians attach great importance to the shape of the head, and the head of every baby is moulded into the desired form, flat-backed, dome-topped, sloping-browed and round, by means of a process of massaging.

The nostrils are deliberately flattened, which is a tribute to the Negroid Melanesians and is a result of the frequent bringing back of Melanesian wives for the harems of the chiefs after raids on Melanesian islands. The Polynesians, especially the women, tend to become stout as they grow older, this is considered a desirable sign of beauty in a woman.

Religion.—The Polynesian religion, like the Melanesian, is simple and animistic, but is enriched with a larger number of imaginative myths. Survivals of sun worship are found in some of the islands, and this is considered an indication of the Indonesian origin of the natives. A fine wooden reproduction of Tangaroa, god of the sea, is preserved in the British Museum, and the Polynesians also adore Ra, the sun god, and Io, the supreme being. However, these Supreme deities are far away from the consciousness of the average Polynesian, who is more inclined to worship the spirits of departed chiefs and ancestors and natural objects in which supernatural power is supposed to reside.

Throughout the Pacific islands there is a general fear of the *aitu*, or supernatural beings, who are conceived as possessing some of the qualities both of gods and of ghosts. Every house has its ghost, and Polynesian folklore contains legends of mysterious lights at sea and of sirens who lure unwary youths to destruction. The souls of great men who have died are invoked by the living, and stones and trees are sometimes regarded as sacred and propitiated with offerings of fruit and pigs. In the past, human sacrifices were sometimes offered, but this practice disappeared as the Polynesians came under the rule of foreign powers.

Social Structure.—The Polynesians, in contrast to the Melanesians displayed a considerable aptitude for social organization. The power of the chief, who is supposed to be in contact with the gods is very great; in some of the larger islands the landowners constitute a kind of native nobility, while the practice of organizing castes or classes of hereditary carpenters, fishermen and persons engaged in other occupations is quite familiar. Foreign visitors to Polynesian islands are often impressed by the dignity and decorum with which general tribal assemblies are conducted. The liquid Polynesian language, with its many vowels, lends itself to oratory. This language is widely understood throughout Polynesia, while in Melanesia there is a babel of local dialects, people of one island often being unable to understand their neighbours on another.

The Polynesians were less addicted to cannibalism than the Melanesians although this practice prevailed in the Marquesas Islands and in New Zealand. The art of the New Zealand Maori wood carver is the finest in the South Pacific. In the figure-heads and stern-pieces of the larger Maori canoes and sometimes in the flutings of the doors, one often finds delicate and refined open-work carving, consisting sometimes of tree-trunk spirals, sometimes of interlacing human figures. There are some remarkable stone ruins throughout Polynesia, and an elaborate system of drains was discovered in a swampy region of northern New Zealand. The Polynesians have long been acquainted with the art of working stones, the remains of huge sanctuaries and stone platforms have been found in Hawaii, the Society Islands, Rarotonga and even on tiny Easter Island. It is possible that the latter represents the remnant of a larger body of land that has been submerged in the ocean, since it is difficult to conceive how the necessarily small population of the present tiny island could have carried out such elaborate construction work. All these stone ruins convey the impression that Polynesia may have possessed a more numerous population and a more developed political and social organization in the past.

Polynesian daily life is strongly affected by the widespread practice of *tabu* (qv) which is so prevalent among primitive peoples all over the world. It is in the hands of the kings and priests. For instance, when Captain Cook wanted to set up an observatory on one of the islands, the priests made the proposed site *tabu* by waving wands over it.

Some chiefs in New Zealand are considered *tabu*, with the consequence that they must be fed, instead of feeding people, all over the world. In the southern part of French Oceania, women are supposed to pop morsels of food into the mouths of the men, but are not permitted to eat with them, as this would be considered a profanation. Before 1819 it was an offense punishable with death for a woman in the Hawaiian group to join in the meal of male relatives.

Tongan Group.—This western outpost of Polynesia is one of the healthiest and most prosperous of the island groups. Elementary education was widely developed, and the people are noted for their comparatively high standard of intelligence. The Tongans are among the most daring navigators of Polynesia and have sent out migrants to

distant islands, such as Rotumah and Ellice, while storm-tossed Tongan canoes landed settlers and trading parties in the outlying Solomon and New Hebrides. Tongan expeditions to Fiji for the purpose of obtaining wood for war canoes were frequent in the years when there was no foreign authority to enforce law and order in the islands.

Declining Islands of Polynesia.—In some of the islands of French Oceania, especially in Tahiti and in the Marquesas group, one finds the spectacle, at once melancholy and curious, of a formerly virile and physically fit people wasting away and tending toward extinction. The native population of Tahiti according to the census of 1911, was less than the number of warriors who turned out from two small districts at the time of Cook's second visit to that island. The physical deterioration after that time was also very marked.

There are two main causes for this decline in population (still more striking in the Marquesas islands than in Tahiti) and for the deterioration in health. Foreigners brought with them into these islands infectious diseases for which the natives possessed no immunity and to which they proved very susceptible. Measles, smallpox and phthisis carried out ravages.

Moreover, the deterioration had set in even before the coming of the foreigners brought the scourge of epidemics for which medical science provided remedies only slowly. The second important cause of the decline of some of the Polynesian islands was the indolence of the natives and the gradual evaporation of their vital energies. This indolence was promoted, because life on these islands, with their luxuriant tropical vegetation, could be maintained with extremely little physical effort. The breadfruit tree, which grows abundantly without artificial cultivation, provides the native with almost everything he needs for his simple food and clothing.

Tribal war was a former stimulus to action among the islanders of the South Seas. When war was repressed by the French authorities, the natives in the islands of the most abundant food supply lost the last antidote to the life of complete sloth that atrophied all their vital faculties. It led naturally to overwhelming decline of population through the usual effect of a high death-rate and a low birth-rate. It is interesting, to note that in the southern islands of French Oceania, where climatic and physical conditions make it necessary for the natives to work for a living, the symptoms of depopulation are absent.

Megalithic Remains.—There is a fascinating reflection of vanished empires, races and civilizations, in the great stone remains found sporadically all the way across the Pacific, from the islands near Japan to tiny Easter island, in eastern Polynesia. There is the deserted Venice of Ponce, there are the stepped pyramids of Samoa, Tonga and Tahiti, the *marae*, or great stone temples of Rarotonga, the Marquesas and Pitcairn island, refuge of the mutineers against Captain Bligh of the "Bounty." The process reaches a climax in Easter island, which has been described as "the most astonishing collection of megalithic monuments in the world."

POLYNESIAN LANGUAGES, a general term for one branch of the great Oceanic family of speech, the other branches being Melanesian, Micronesian and Indonesian. These four divisions are so clearly marked off from each other and so definitely spring from one common parent that it is customary to refer to the individual languages of each group as mere dialects. The existing differences between the languages as we know them, however, are such as to justify the use of the term languages.

The principal members of the Polynesian group are (a) Samoan (probably the oldest form of Polynesian speech extant), (b) Maori, (c) Tahitian, (d) Hawaiian, (e) Tongan, (f) Mangarevan, (g) Nukuhivan (of the Marquesas Islands) and (h) the dialects of the Paumotu archipelago. From these main tongues dialects and sub-dialects have developed until Polynesia has almost a hundred variants of the original tongue.

Phonetics.—The Polynesian languages are amazingly rich in vowels with striking consonantal poverty. Although possessing only the five vowels *a, e, i, o, u*, in a short and long form the musical register of the Polynesian voice is so wide as to produce the illusion of numberless variants of these vowels. The *i* in particular is occasionally so shrill that no European can satisfactorily reproduce it.

The consonants are *k, t, p, s, (h), i, (v), ŋ, n, m, f, (v), (w)*. No single Polynesian tongue contains all these consonants, those in parentheses being alternatives in some languages for the letter immediately preceding. Fakaao is one of the richest of these tongues having *k, t, p, s, i, v, i, ŋ, n, m, f*; most of the others lack two or three of this number. Maori has, in addition, a

compound or aspirated consonant *wh* which sounds very like an aspirated *v*, as in *whaka*-, the prefix of causative verbs. A tabular view of the phonetics of the chief Polynesian languages follows.

A Vowels

o	o	o	o	o	o	o	o	o	o
u	u	u	u	u, i	u	u	u	u, i, o	u, o

Thus, *e, i, and o* are constant; *a* and *u* variable. But so jealously are vowel-values guarded by Polynesian speakers that these changes are constant within the bounds set by any particular language and it is possible for the speaker of one idiom to say definitely what form a word will take in another whose phonetic system he knows.

B Consonants

Hawaiian	Fakaao	Samoan	Tongan	Maori	Rarotongan	Mangareva	Paumotu	Tahiti	Nukuhiva
k	k	k	k	k	k	k	k	k	k
t	t	t	t	t	t	t	t	t	t
p	p	p	p	p	p	p	p	p	p
h	h	h	h	h	h	h	h	h	h
f	f	f	f	wh	f	f	f	f	f
w	w	w	w	w	w	w	w	w	w
i	i	i	i	i	i	i	i	i	i
ŋ	ŋ	ŋ	ŋ	ŋ	ŋ	ŋ	ŋ	ŋ	ŋ
n	n	n	n	n	n	n	n	n	n
m	m	m	m	m	m	m	m	m	m

Variability is much more frequent among the consonants than with the vowels, which are the backbone of Polynesian speech. *k* is constant except in Hawaiian, Samoan and Tahiti speech where it is replaced by a glottal check; *t* is constant except in Hawaiian where it becomes *k*, e.g., Maori *tanata*, a man, Hawaiian *kanaka*, Nukuhiva *kenata*, enata. *p*, *n* and *m* do not change at all and *l* and *r* appear alternately. The Samoan and Fakaao *s* for *h* in the other languages, betrays the sibilant sound of *h* before a weak vowel (an analogy is found in Luchuan and Japanese *hito*, *fito*, pronounced *shito*). All the changes illustrated in the table are regular and very few exceptions are found.

Morphology.—Syllables in Polynesian tongues may begin with a consonant or a vowel but must always end in a vowel. From this it results that many vowels come together in groups of several syllables, extreme cases are *hoioioio, mou'a, kawi-keaoi*. Here, however, each successive vowel is a syllable, there being no true diphthongs in these languages. There is no vowel elision, and the accent (penultimate), is very light, so that each syllable is clearly enunciated. But owing to the Polynesian distaste for consonants many homophones are created, mostly consisting of two vowels, e.g., Nukuhiva *ua* means "rain," "two," "to heat," "lobster," etc., from elision, the original words being *uka* or *uwa*, *rua*, *ura*, and *uka*. The genus of the language can be clearly seen from the borrowings from foreign languages, chiefly from English, e.g., the word "quarter" appears as *tuata*, "governor" as *tavana* or *kavana*, "doctor" as *tacte*, etc.

In normal words, when compounds are made the accent shifts so as to fall still on the penultimate syllable, e.g., Samoan, *ave* to give, *avea* to be given, Hawaiian, *lohe* to hear, *lohéa* to be heard. But there are exceptions to the rule of penultimate accent, which must be learnt by practice only: most of these, which are not numerous, arise from the difficulty of distinguishing between homophones or from the need of distinguishing a common word from one which has become *tapu* as the name of a

chief or other prominent person

One phenomenon of Polynesian speech deserves attention, viz., reduplication, complete or partial. Many new words are built up in this way and delicate nuances are conveyed by the doubling of a single syllable. In Maori *haere* conveys the idea "going," *haerehaere* means "roaming about, take a walk"; Samoan *tufa*, "divide," yields, *tufatufa*, "to split up into many pieces," etc.; Maori *nui*, "to drink" gives *nui*, "to tupples, soak"; Tahiti *parau*, "to speak" gives *paraparau*, "to chatter"; from Tonga *nofo*, "to live" comes *nonofu*, "to live with someone." Adjectives are treated in the same way. Rarotongan *nua*, "big" gives *nunua*, "very big"; Hawaiian *lā*, "small," gives *lālā*, "very small."

Word-building is simple. From *tama*, "a child" and *ariki*, "a chief" is made *tamariki*, "a son" (lit. a princeling, noble child); from *tama*, "a child" and *wahine*, "a woman," comes *tamahine*, "a daughter, a girl"; *uritaata*, "an ape" is made up of *uri*, "a dog," and *taata*, "a man."

The article differs from language to language, the indefinite article is usually identical with the numeral one, (*se, se*). This is not used, however, unless absolutely necessary, although the definite article (Samoan, *o le* or *le*, Hawaiian, *he*, Maori, *te*, Tahiti, Rarotongan, Mangarevan, Nukuhiva *e*), usually appears before a noun. Maori has a plural article *na* (*nga*), and the other languages have prefixes which mark the noun as plural although nouns undergo no change in form from singular to plural.

There are cases in the language marked by prefixes. The noun as agent is preceded by *ko* ('*o*), the genitive is occasionally still shown by position (as was the original method) although the prefixes *na, a, no, o* are now usually employed. The dative case is shown by a prefixed particle *ki* (before proper names and pronouns *hia*) and the accusative (when it is marked at all) is preceded by *z* or *ia*. The particle preceding the noun in the ablative case is *e* and in one or two languages there are other prefixes, but these do not actually form part of a genuine declension. The vocative case is marked by the syllable *e* preceding the name or noun.

The adjective suffers no change in any of the languages and it follows its noun except when it is used as a predicate when it precedes it, Samoan *laia tele*, "a big tree." When the adjective follows its substantive as attribute, the plural of the whole phrase is accomplished by the reduplication of the adjective. Maori, *ika pai*, "a good fish," *ika papai*, "good fish"; Hawaiian, *hale nui*, "a big house," *hale nunu*, "big houses."

The pronouns are complex in Polynesian speech, there being singular, dual and plural forms with inclusive and exclusive varieties. The normal forms are:—

	1st person	2nd person	3rd person
Singular	<i>aku</i>	<i>ko</i>	<i>ia, na</i>
Dual	<i>ia-rua</i>	<i>ko-rua</i>	<i>ra-rua</i>
Dual (exclusive)	<i>ma-rua</i>	<i>mo-rua</i>	<i>no-rua</i>
Plural	<i>ia-loru</i>	<i>ko-loru</i>	<i>ro-loru</i>
Plural (exclusive)	<i>ma-loru</i>	<i>mo-loru</i>	<i>no-loru</i>

These forms vary according to the dialect and the consonant-changes tolerated therein. There are full and contracted forms for the possessive and demonstrative pronouns which are also complicated. The interrogative pronoun serving many purposes is *wai* (Maori and Hawaiian); *vai* (Tahiti); *ka* (Tongan); and *ai* for the other dialects, used only for living things and for inanimate objects, *aha* (Maori, Hawaiian, Nukuhiva), *ka* (Tongan), *aa* (Rarotongan), and *a* in the other tongues. There is no relative pronoun in any of the languages—either it remains unexpressed or a circumlocution is employed with the personal or demonstrative pronoun.

The Polynesian verb, like the noun and adjective, undergoes no change in form, and all moods and tenses are indicated by participles prefixed to the root form of the verb. The verb has no special form to distinguish it from other parts of speech, and, indeed, many adjectives are used as verbs without change.

The passive voice is constructed from the active by the use of the participle prefix *ia* (*hia, ia, hia, hma, msa, etc.*), the causa-

tive is similarly produced by the prefix *fa'a* (*whaka, ha'a, aha, etc.*). A desiderative is formed by the prefix *fia* (*fe, hua*), and one verbal suffix exists whereby a reciprocal form is made (*-aki, -faki, -laki, -taki, -raki*).

The present indicative is shown by the participle *e* or *te*, the future by *a*, and the preterite by *na*. The moods are few and vary greatly between the languages, the most common being *ia* (*hia, ke*) for the conjunctive, *a, ka, hae, pea, poo, ahuri, ma*, etc. for the conditional and *fau* (Tonga only) for the potential. The particle *ana*, *a'a* makes the participle

Numerals									
	Hawaiian	Fakalofo	Samoan	Tongan	Maori	Rarotonga	Tahiti	Nukuhiva	
1	<i>kahi</i>	<i>tasi</i>	<i>tasi</i>	<i>kahi</i>	<i>tahi</i>	<i>tai</i>	<i>tahi</i>	<i>tahi</i>	
2	<i>lua</i>	<i>lua</i>	<i>lua</i>	<i>lua</i>	<i>rua</i>	<i>rua</i>	<i>rua</i>	<i>rua</i>	
3	<i>kohi</i>	<i>tolu</i>	<i>tolu</i>	<i>tolu</i>	<i>toru</i>	<i>toru</i>	<i>toru</i>	<i>toru</i>	
4	<i>he</i>	<i>fa</i>	<i>fa</i>	<i>fa</i>	<i>wa</i>	<i>wa</i>	<i>wa</i>	<i>wa</i>	<i>fa, ha</i>
5	<i>lima</i>	<i>lima</i>	<i>lima</i>	<i>lima</i>	<i>rima</i>	<i>rima</i>	<i>rima</i>	<i>rima</i>	<i>ma</i>
6	<i>ono</i>	<i>ono</i>	<i>ono</i>	<i>ono</i>	<i>ono</i>	<i>ono</i>	<i>ono</i>	<i>ono</i>	<i>ono</i>
7	<i>hiku</i>	<i>fitu</i>	<i>fitu</i>	<i>fitu</i>	<i>whitu</i>	<i>whitu</i>	<i>whitu</i>	<i>whitu</i>	<i>fitu, hiku</i>
8	<i>walu</i>	<i>valu</i>	<i>valu</i>	<i>valu</i>	<i>waru</i>	<i>waru</i>	<i>waru</i>	<i>waru</i>	<i>valu</i>
9	<i>siva</i>	<i>ma</i>	<i>ma</i>	<i>hina</i>	<i>siva</i>	<i>siva</i>	<i>siva</i>	<i>siva</i>	<i>siva</i>
10	<i>nui</i>	<i>fulu</i>	<i>sefulu</i>	<i>hohofulu</i>	<i>hahuru</i>	<i>hahuru</i>	<i>ahuru</i>	<i>onohuru</i>	

The word for "five" (*lima*) is the general word for "hand" in Polynesia, the word for "ten" is borrowed from Malay *puluh*. The identity between the words of the languages is rarely so close as it is with the numerals and a few terms of relationship. The ordinal numbers are formed by placing the definite article before the cardinals, e.g., Tahiti, *o te rima* (lit. "the five") "fifth", Samoan, *o le lua*, "the second," etc.

Vocabulary.—The Polynesian tongues are rich in terms of relationship, in names of natural objects, fish, birds, plants, flowers and phenomena of nature, all the winds and zephyrs, all kinds of clouds, waves, streams, hills, shores and so on having special names. There is a shortage of abstract terms, metaphor is common, a concrete noun doing double duty. Maori and Samoan, however, in the philosophical chants (see POLYNESIAN LITERATURE) have developed a definitely abstract vocabulary. There is a decided lack of direct, forceful words and in translation from European languages it is difficult to turn decisive phrases into Polynesian equivalents. The vocabularies suffice for all ordinary purposes and a little ingenuity often turns an English phrase into a telling South Seas equivalent.

BIBLIOGRAPHY.—The *Journal of the Polynesian Society* (Wellington, N.Z.), a quarterly publication in which many excellent sketches of the grammar of Polynesian languages have appeared is most important. For early researches into Polynesian speech see Wilhelm von Humboldt, *Über die Keeser-Sprache* etc. (1836-39); Lorrin Andrews, *A Grammar of the Hawaiian Language* (Honolulu, 1854); Friedrich Müller, *Grundriss der Sprachwissenschaft*, II, part 2 (1882). The dictionary par excellence is Edward Tregear's *Maori-Polynesian Comparative Dictionary* (Wellington, N.Z. 1904) wherein is to be found the most complete bibliography of Polynesian linguistic works. See also Meillet and Cohen, *Les Langues du Monde* (1924), pp. 450-455.

(A. N. J. W.)

POLYNESIAN LITERATURE. A few decades ago this title would have been deemed an anachronism, or worse, but since the publication of the Sacred Songs of the Hula by Dr. N. B. Emerson under the title *Unwritten Literature of Hawaii* (1909), it has been generally conceded that the Polynesians, like other illiterate races, may have a literature in the true sense of that term. The old Polynesian priests with their extraordinary memories held every word of the old traditions as faithfully as papyrus or paper could have done; the proof of this lies in the presence, in texts taken down from native lips, of words so archaic that even the hierarchs have forgotten their meanings. It soon came to be realized that this wealth of literature was rapidly dying with the chiefs who were its last repositories, and numerous legends and collections of songs were taken down from the lips of the *kahunas* or sorcerers.

The literature of the Samoan Islands is probably older than that of any other part of Polynesia and is wonderfully akin to the old Maori philosophical chants. The *Creation Song* in Samoan is not only interesting as folklore, it is a marvellously dignified piece of poetic literature.

Long genealogies interspersed with legends of philosophic and historic import became available in Roman script, providing much material for the study of the history and language-development of the Pacific islands. Many migration songs and legends are known and there is still time to collect others. The whole text of the *awa* ceremonial and similar ritual texts also became available and there is reason to believe that a close study of others collected would prove of the greatest possible value in the solution of problems of migration and tribal mixing.

Maori literature is of two kinds, philosophic and traditional-historical. The *Maori Chant of Eternity*, in places, identical with the Samoan *Creation Song* but has a definite individuality. Speculation on life and its problems appears in many of the legends centred round *Mau*, the great common Polynesian ancestor, the divine angler, whose hook caught on the islands of New Zealand and brought them to the surface as an abode for his children. *Hawaiki*, that mysterious far land, renowned in Polynesian song, is vaguely glimpsed, now as a paradise to which men's souls shall go, now as the Eden from which the ancestors of the singers emerged countless centuries before. The stories of the creation of the cosmos and its peopling are all before us in Maori speech, put together with a reverence and delicacy of phrase worthy of any literature.

Hawaiian literature is essentially romantic. The *hula*, a religious performance, was in its essence an ebullition of joyous animal spirits, outflowing toward nature. The abandonment seen by some in the dance and in the words of the songs is largely imaginary although it is undeniable that much of the *hula* and *mele* literature of Hawaii is made up of protracted *double-entendres*. In the Hawaiian one can observe a close love of nature through understanding, the trees wave in a warm breeze and the sunlight glints on azure waves because the singer is happy and because the gods are weaving anew their ancient spell of poetic song. Even the dread voice and searing tongue of Pele, the awful volcano-goddess, can be wooed by song and dance, to rest. The allusions in the songs and prose of Hawaii point to a long cultural experience and deep reverence for tradition. The lyrics of Hawaii rank high among the pure rhapsodies of the world.

The literature of other Polynesian islands is largely a repetition of that outlined above. The traditions of Tonga supply lacunae in the stories of Samoa and New Zealand and those of Tahiti supplement those of Hawaii and the Gambier Islands. In all, however, they are distinctive songs and chants, as full of beauty as they are of scientific interest.

POLYNOMIAL, in elementary algebra, an expression composed of two or more terms combined by operations of addition or subtraction. Thus $\frac{1}{2}a + 7b + c$ and $2 + a - \sqrt{\frac{1}{2}xy} + x^2$ are polynomials. A polynomial of two terms is called a binomial, and one of three terms is called a trinomial. An expression consisting of a single term is called a monomial.

The word polynomial is often used with a more technical meaning, particularly in higher mathematics, to characterize the manner of dependence of an expression on one or more quantities regarded for the time being as independent variables. Importance attaches then to the nature of the operations performed on the variables, rather than to the number of terms, and monomial expressions of suitable form are admitted as special cases. Under this interpretation, which will be adopted throughout the rest of the article, a polynomial in one variable is a sum of terms, each consisting of a power of the variable multiplied by a coefficient independent of the variable, or, as an extreme case, a

single such term, in a polynomial in several variables, each term contains a power of one of the variables or a product of powers of two or more of them. By a power in this connection is meant a power with exponent equal to a positive whole number or zero. The highest exponent that occurs, or, in the case of more than one variable, the highest value attained by the sum of the exponents in a single term, is the degree of the polynomial. Thus $ax^2 + bx + c$ is a polynomial of the second degree in x (if $a \neq 0$), and $x^2 + 3xy^2 - 8xy^4$ is a polynomial of the third degree in x and of the fourth degree in y (the latter is also said to be of the fifth degree in x , and of the fourth degree in y).

Having fundamentally a relative sense, the definition is applicable to characterize the manner of dependence on quantities which may themselves be more or less complicated expressions of any form. Thus $ax^2 + bx + c$, $a(1 + \sqrt{x})^2 + b(1 + \sqrt{x}) + c$, $a/x^2 + b/x + c$, a $(\log x)^2 + b \log x + c$ are polynomials with respect to x , $1 + \sqrt{x}$, $1/x$, and $\log x$ respectively, though the last three are not polynomials with respect to x , and $ax^2 + bx^2 + c$, a polynomial in x , can also be regarded as a polynomial in x^2 . The sum, difference, or product of two polynomials is a polynomial, their quotient in general is not. Polynomials and quotients of polynomials are known collectively as rational functions.

In elementary algebra, expressions coming under the more technical definition of polynomials are studied largely in connection with the equations formed by setting them equal to zero. If $f(x)$ denotes the polynomial

$$a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_{n-1}x + a_n$$

where $a_n \neq 0$, then the so-called "fundamental theorem of algebra" ensures the existence of a root r of the equation $f(x) = 0$. The number r is a complex number, or as a special case a real number, and the fact that $f(r) = 0$ implies that $(x - r)$ is a factor of $f(x)$. By a repetition of this argument one can show that $f(x)$ can be factored in the form

$$f(x) = a_0(x - r_1)(x - r_2) \dots (x - r_n)$$

where the r_i are the roots of $f(x) = 0$. This factorization is uniquely determined. If the factor $(x - r)$ occurs exactly h times in the factorization then r is said to be a root of multiplicity h of the corresponding equation.

The resolution of a polynomial into linear factors makes essential use of the availability of all complex numbers as coefficients. If a more restricted system of coefficients is employed, such a factorization may not be possible. For example, $x^2 + 1$ is irreducible if real numbers only are allowed as coefficients, and $x^2 - x + 2$ is irreducible if rational numbers only are allowed. As these examples show, it is necessary in any discussion of factorization to specify the coefficient domain. If the domain denoted as F in $F[x]$ is customary to denote the system of all the polynomials in x with coefficients in F by $F[x]$, and more generally, the system of all polynomials in x_1, x_2, \dots, x_n with coefficients in F by $F[x_1, x_2, \dots, x_n]$. If F is a field (e.g., the set of all complex numbers, the set of all real numbers, the set of all rational numbers) then a polynomial belonging to $F[x]$ is called irreducible if it cannot be expressed as a product of polynomials in $F[x]$ of lower degree. Every polynomial in $F[x]$ which is not itself irreducible can be resolved into irreducible factors in this domain and apart from the order of the factors and from constant factors, can be so resolved in only one way. A similar definition of irreducibility can be used in the domain $F[x_1, x_2, \dots, x_n]$ and there, too, the unique factorization theorem holds. In a slightly modified form the theorem holds also for other polynomial domains (See, for example, A. A. Albert's *Modern Higher Algebra*, 1937).

It is an important fact in trigonometry that the cosine of n times an angle, when n is a whole number, can be expressed as a polynomial of the n th degree in terms of the cosine of the angle itself, e.g.,

$$\cos 2x = 2 \cos^2 x - 1, \quad \cos 3x = 4 \cos^3 x - 3 \cos x, \\ \cos 4x = 8 \cos^4 x - 8 \cos^2 x + 1.$$

The sine of nx can be expressed as the product of $\sin x$ by a polynomial of the $(n-1)$ th degree in $\cos x$ when n is odd, but not when n is even. It can also be expressed as a polynomial of the n th degree in $\sin x$; e.g.,

$$\sin 2x = 2 \sin x \cos x, \quad \sin 3x = \sin x (4 \cos^2 x - 1) = 3 \sin x - 4 \sin^3 x$$

The relation between algebra and trigonometry was emphasized by François Viète (1540-1603), who contributed largely to the advancement of both branches.

Analytic geometry is largely concerned with the geometric interpretation of the equations obtained by setting polynomials in the co-ordinates equal to zero. In the plane, an equation of the first degree, of the typical form $Ax + By + C = 0$, represents a straight line, i.e., if (x, y) are the rectangular co-ordinates of a point, all points whose co-ordinates satisfy the equation lie on a straight line, and all points of the line have co-ordinates satisfying the equation. The conic sections (i.e., ellipses, circle (which may be regarded as a special case of the ellipse), parabola, hyperbola (e.g., $x^2 - y^2 = 1$), and certain "degenerate" forms (pairs of straight lines)—are represented by equations of the second degree, of the form

$$Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0,$$

where in particular cases one or more of the coefficients may be equal to zero. René Descartes (*Géométrie*, 1637) and his contemporary, Pierre

de Fermat, are regarded as the founders of analytic geometry ($q\ v$). The curves represented by equations of the third degree were systematically studied by Sir Isaac Newton (1704). In three dimensions, an equation of the first degree, $Ax + By + Cz + D = 0$, represents a plane, and one of the second degree a *quadratic surface*: ellipsoid, sphere (a special case of the ellipsoid), hyperboloid (of one sheet or of two sheets), paraboloid (elliptic or hyperbolic), cone, cylinder ($q\ q\ v$), or, as a degenerate form, a pair of planes.

The study of curves and surfaces defined by polynomial equations of arbitrary degree constitutes the field of algebraic geometry. A fundamental concept in the modern development of this subject is that of a polynomial ideal, defined to be a set I of polynomials such that (1) the difference of any two polynomials that belong to I also belongs to I , and (2) the product of any polynomial in I by any polynomial belongs to I . If $u_1(x, y)$, $u_2(x, y)$, ..., $u_r(x, y)$ are fixed polynomials then the totality of polynomials of the form

$$f_1(x, y)u_1(x, y) + f_2(x, y)u_2(x, y) + \dots + f_r(x, y)u_r(x, y)$$

where the $f_i(x, y)$ range independently over the polynomial domain, is an ideal. The polynomials $u_1(x, y)$, ..., $u_r(x, y)$ are said to form a basis for this ideal. An important theorem due to David Hilbert (1890) asserts that any polynomial ideal has a finite basis.

The theory of the transformation of homogeneous polynomials, or forms (see ALGEBRAIC FORMS), by linear substitutions in the variables, and of the invariants and covariants associated with such transformation, is an important branch of algebra with numerous applications. For example, if x, y, z are polynomial $ax^2 + bxy + cy^2$ are expressed, in terms of a new pair of variables u, v , by the relations

$$x = \alpha u + \beta v, \quad y = \gamma u + \delta v,$$

where $\alpha\delta - \beta\gamma = 1$, it is found that $ax^2 + bxy + cy^2$ is identically equal to an expression of the form $Au^2 + Buv + Cv^2$ in which $B^2 - 4AC = b^2 - 4ac$, a fact which is of fundamental significance in analytic geometry. More generally, for any values of $\alpha, \beta, \gamma, \delta$,

$$B^2 - 4AC = (\alpha\delta - \beta\gamma)^2 (b^2 - 4ac)$$

The expression $b^2 - 4ac$, itself a polynomial in terms of the coefficients a, b, c , is called an invariant.

Polynomials in one variable are the simplest class of functions from the point of view of the calculus, because the rules for their differentiation and integration are particularly simple, and are obtained immediately from the definitions of these processes. The result of differentiating or integrating a polynomial with respect to its independent variable is always a polynomial.

In the modern theory of functions (see FUNCTION), any polynomial is a continuous and analytic function of its variables. If a function of a single complex variable z is analytic for every finite value of z , and becomes infinite when z , represented by a point in a plane, goes to infinity in an arbitrary manner, the function is necessarily a polynomial.

Applications.—Apart from their specific properties, polynomials are of fundamental importance from their use in the approximate representation of other functions. The standard functions of elementary analysis can be represented by power series (see SERIES), of the form

$$c_0 + c_1x + c_2x^2 + c_3x^3 + \dots \quad (\text{Maclaurin's series}),$$

or, more generally,

$$c_0 + c_1(x-a) + c_2(x-a)^2 + c_3(x-a)^3 + \dots \quad (\text{Taylor's series}),$$

which reduces to the preceding when $a=0$; the sum of an infinite series is by definition the limit approached by the sum of a finite number of its terms, as the number of terms is taken larger and larger, and the sum of a finite number of terms of a power series is a polynomial. Representation by power series can be made the basis for a systematic treatment of analytic functions of a complex variable. Another important form of development in series, theoretically applicable with greater generality, proceeds in terms of the polynomials of Adrien Legendre (1752-1833) or Legendre's coefficients. These may be defined as the coefficients of successive powers of x in the power series for $(1-x^2+x^2)^{-1/2}$. One of their most striking properties is that the product of any two of them, integrated over the interval from -1 to $+1$, gives zero. Legendre polynomials have been found to be of great value in mathematical physics, especially in quantum mechanics.

$x=0$	$y=3$	$\Delta y=8$	$\Delta^2 y=2$
1	11	10	2
2	21	12	2
3	33	14	2
4	47	16	2
5	63		

The first column contains values of x , and the second, the corresponding values of y . The entries in the third column, obtained by subtracting each y from the following, are the first differences. The last column is made up of the differences of the first differences, which are called second differences, and in the present instance are all equal. It is clear that by means of this property the table could be continued further, without direct substitution in the original formula. (See CALCULUS OF DIFFERENCES.)

MacLane, *A Survey of Modern Algebra* (1941) (D. J. A. N. J.)

POLYP, the name applied technically to an individual animal of given form, which is of frequent occurrence among those creatures known as the Coelenterata (e.g., sea anemone, coral polyp, *Hydra*). The word polyp derives from the French *poulpe* (octopus). The form of a polyp is outlined in the article COELENTERATA (See also HYDROZOA, SCYPHOZOA; ANTHOZOA.)

POLYPHEMUS, the most famous of the Cyclops, son of Poseidon and the nymph Thoosa. Odysseus, having been cast ashore on the coast of Sicily, fell into the hands of Polyphemus, who shut him up with 12 of his companions in his cave and blocked the entrance with an enormous rock. Odysseus at length succeeded in making the giant drunk, blinded him by plunging a burning stake into his eye while he lay asleep, and with six of his friends (the others having been devoured by Polyphemus) made his escape by clinging to the bellies of the sheep let out to pasture. See CYCLOPES, ACTIS, ODYSSEUS.

POLYPODIUM, an inclusive genus of ferns containing about 600 species; widely distributed throughout the world, but specially developed in the tropics. Sometimes it is divided into ten or more "natural" genera. The name is derived from Gr. $\pi\acute{o}\lambda\upsilon\varsigma$, many, and $\pi\acute{o}\delta\omicron\nu$, a little foot, on account of the foot-like appearance of the rhizome and its branches. The species differ greatly in size and general appearance and in the character of the frond, the sort or groups of spore cases (*sporangia*) are borne on the back of the leaf, are globose and naked, that is, are not covered with a membrane (*indusium*). The common polypody (*P. vulgare*) of Europe, Asia and western North America is widely diffused in the British Isles, where it is found on walls, banks, trees, etc.; the creeping, densely scaly rootstock bears deeply pinnately cut fronds, the fertile ones bearing on the back the bright yellow naked groups of sporangia. It is also known as adder's foot, golden maidenhair and woodfern. There are a large number of varieties, differing chiefly in the form and division of the pinnae, var. *cambricum* (originally found in Wales) has the pinnae themselves deeply cut into narrow segments, var. *serratum* has the pinnae serrate. Besides the well-known polypody of eastern North America (*P. virginianum*), very similar to the foregoing, several other species occur in the southern and western states.

POLYPUS, a term signifying an outgrowth which is attached by a narrow neck to the walls of a cavity lined with mucous membrane, such as the nose, bladder or rectum. (See TUMOUR.)

POLYTECHNIC. This term, common to many languages, is ordinarily used, by itself or with the word "institute" or, more rarely, "school," to denote an educational establishment equipped to teach many subjects (Greek $\pi\acute{o}\lambda\upsilon\varsigma$, "many"), but mainly if not exclusively scientific and technological studies and processes ($\tau\acute{\epsilon}\chi\eta\eta$, "art" or "craft"). It has also been used occasionally to describe other kinds of establishment designed to encourage inter-

est in the arts and sciences, and in one instance at least has been applied to a large shop with many departments.

In general, a polytechnic institute offers instruction to students beyond school age, though it may include a secondary school organized as a separate department. But the exact significance of the name varies almost with every establishment or, as in England, group of establishments. In France, where it appears to have been first used, the name *école polytechnique* was applied in 1795 to the *École des Travaux Publics*, founded a year previously in Paris by the National convention to advance scientific knowledge and in particular to train engineers for the army. The sobriquet, originating by way of protest against the almost exclusive devotion to literary and abstract studies then common to French places of higher education, became and remained the institution's official title, but the *École Polytechnique* stayed predominantly a school of military and civil engineering and therefore, strictly speaking, rather a monotechnic than a polytechnic. Similarly, the *Faculté Polytechnique* of Mons, Belg., is restricted to engineering studies, though the range is wide, and the same applies to the *Polytekniske Laereanstalt* at Copenhagen, Den. The *Istituto Politecnico* at Milan and Turin, It., and the *Polytechnion* at Athens, Gr., have faculties of architecture as well as engineering. The famous *Eidgenössische Technische Hochschule* (Swiss Federal Institute of Technology), frequently referred to as the *Zürich Polytechnikum*, is as good an example of a polytechnic in the literal sense as can be found. It is organized in 12 schools which include, in addition to civil, mechanical, electrical and agricultural engineering, subjects as varied as forestry and pharmacy, and there is also a department of optional subjects embracing literature, history, economics, politics and philosophy. All the foregoing institutions are either universities in their own right or hold university status. The location, character and status of educational establishments in Communist Europe were liable to change at a moment's notice, but at mid-20th century there were reported to be polytechnic institutes in Poland at Warsaw, Gdańsk, Gliwice, Łódź and Wrocław (Breslau) and in Rumania at Bucharest, Jassy and Timişoara. Most if not all of these appear to have been degree-granting institutions and mainly if not entirely devoted to technological studies.

London.—In England the title "polytechnic" is almost restricted to the members of a group of educational institutions founded in London during the latter part of the 19th century with the dual purpose of providing vocational and other educational facilities for young working people and of promoting definite religious, social and civic ideals. These London polytechnics and their distinctive aims and organization derive from the initiative of *Quintin Hogg* (1845-1903), who as a young man of 19 shortly after leaving Eton college began a lifetime of evangelistic and educational pioneering by teaching street urchins to read. His first "classroom" was under the archways of the Adelphi on the north side of the Thames. In 1871 he opened a *Youths' Christian Institute* in Castle street (moved to larger premises in Long Acre in 1878) for young shop assistants and artisans between the ages of 16 and 21. This he developed to provide, in addition to the optional Bible classes and other religious exercises which were the basis of his enterprise, a wide range of educational, social and athletic activities including, despite lack of support from employers and opposition from trade unions, classes for instruction in the building and other trades.

So successful was he that by 1880 he was looking for larger premises. As it happened, about this time there was offered for sale a building in Regent street called the *Royal Polytechnic Institution*. It had been opened in 1838 to advance "practical science" and for many years enjoyed much popularity as a resort where the demonstration of scientific novelties was pleasantly tinted with entertainment. *Hogg* bought it, retained the name and reopened his institute there in Sept. 1882, with accommodation for 2,000 members. By the end of the winter session there had been 6,800 applications for membership. As he refused to increase the modest fees or to accept any subventions which involved compromise of the religious principles on which he based his work, *Hogg* for some years incurred heavy financial losses. But this did not

deter him from continuing to build up the "Poly," as it soon came to be affectionately called, into a many-sided educational and social institution, providing instruction "in subjects ranging from the domestic arts to carriage-building, photography, and goldsmith's work" (*Ethel M. Hogg, Quintin Hogg, a Biography*, London, 1904) and offering its members reading rooms, library, gymnasium, billiard room, refectory, concerts, country excursions and a wide range of athletic activities. Members were also encouraged to co-operate in the management of the Poly and in the maintenance of good discipline. From the start women were admitted to classes, and in 1885 a separate institute was opened for them under the direction of Mrs. Hogg. In 1886 a school was started for boys and girls which gave special attention to manual, domestic and commercial subjects.

The resounding success of the Regent Street polytechnic naturally suggested the foundation of other establishments on the same model, and happily funds became available. In 1878 a royal commission had been appointed to inquire into the parochial charities in the City of London; it was felt that because of the increase in their value and the decrease, or disappearance, of the kind of beneficiaries whom they were founded to aid, the total annual income was far greater than was required to provide adequately for all the designated objects of these charities. The outcome of the commission's report was the City of London Parochial Charities Act, 1883. This provided that the charities in 107 of the city parishes (that is, in all save five of the largest) should after seven years be administered by a corporate body to be called the Trustees of the London Parochial Charities. A scheme was drawn up by the charity commissioners whereby that part of the income from the consolidated charities which was allocated to secular purposes was to go toward the establishment and maintenance of "industrial" and recreative institutes similar to *Hogg's* polytechnic, and *Walter Besant's* People's palace in the Mile End road, for the benefit of the poorer classes of the working population of London. The commissioners' offer of these funds was made conditional upon the raising by voluntary effort of an amount approximately equal to the capitalized value of the endowment. Local committees were set up, valuable gifts were given by private benefactors, and subscriptions were received from *hvy* companies, charities and individuals. A total sum of more than £500,000, including grants made by the charity commissioners and the Trustees of the London Parochial Charities, was raised for capital expenditure. As a result, between 1891 and 1896 six new polytechnics opened their doors. Chelsea (1891), Woolwich (1891), Borough (1891), Battersea (1891), Northampton (in St. John street, 1896) and Northern (1896). A seventh was planned in the scheme, but lack of local support, delay in securing possession of the site and the incidence of World War I prevented the North-Western from opening before 1919.

The Trustees of the London Parochial Charities, at conditions for making grants toward the maintenance of the polytechnics "laid down as their principles that the institutions which benefited should give instruction in the principles of the arts and sciences which underlie crafts and in the application of such principles to particular trades, that they should be a supplement and not in substitution for the workshop or place of business, that they might give instruction suitable for intending emigrants and hold lectures and concerts, encourage gymnastics, drill, swimming, and other forms of bodily exercise, and institute clubs and societies, libraries, museums and reading rooms, that their educational facilities should be equally open to both sexes, that the fees should be small, and that drinking, smoking and gambling should be prohibited" (R. L. Archer, *Secondary Education in the XIX Century*, Cambridge University Press, 4th impression, 1937). Membership was restricted, except in special cases, to not exceeding 5% of the total, to persons between the ages of 16 and 25.

Large as they were, the funds available from the London Parochial Charities trust were quite inadequate to maintain the great establishments to which they were committed. But aid was at hand from another source. In 1893 the London county council, empowered under the Technical Instruction Act, 1889, to make limited grants in aid of technical education and also having had funds placed at its disposal for the purpose by the Local Taxation (Customs and Excise) Act, 1890, devoted a considerable portion of the latter to the development and sustenance of the polytechnics. Thereafter an increasing percentage of their revenue came from public funds. The Education Act, 1902 (as applied to London by its Act of 1903), by making the council responsible for all education in its area, tended to diminish distinctions between the grant-aided polytechnic and the wholly maintained technical institutes set up by the council. The Education Act, 1917, which empowered the council (in common with the other local authorities) to promote social and physical well-being and to co-ordinate all forms of education within its area, continued the process of assimilation; and the Education Act, 1944, by transforming these powers into statutory duties, advanced it still further. The distinction between a polytechnic and a major technical college in London became increasingly managerial rather than educational.

The London county council from the start endeavoured to secure

that the educational facilities in the polytechnics and technical institutes should be so disposed as best to meet the particular needs of any given district, and the governing bodies of the polytechnics from time to time accepted suggestions to this end from the council involving important revisions of their educational programs. For example, facilities for more specialized technologies were concentrated at individual establishments. Thus Battersea has in addition to important departments of engineering and chemistry one of hotel training and domestic science, Chelsea a department of pharmacy and a school of art, and the Regent Street Polytechnic schools of architecture and commerce and a department of management studies. The Borough houses the National College of Heating, Ventilating, Refrigeration and Fan Engineering, established in 1948 to give technological education at the highest level to selected persons in these industries. Similarly, the Northampton houses the National College of Horology and Instrument Technology (established 1947), and the Northern, temporarily, the National College of Rubber Technology (established 1948). The location of these national colleges was a tribute to the outstanding work previously done by the respective polytechnics in the technologies concerned. The Northern contains also a department of radio and musical instrument technology, and the Northampton one of furrier.

Five of the polytechnics—Battersea, Chelsea, Northampton, Northern and Woolwich—prepare students in some subjects for internal degree examinations of the University of London. These polytechnics are not organically linked with the university, but the faculties concerned have on their staff members whom it accepts as "recognized teachers." This arrangement dates from the reconstitution of the university in 1962. (H C D)

United States—The term "polytechnic" as used in the United States generally refers to a postsecondary educational institution offering various curricula in technology, science and possibly agriculture. There is no essential difference between a polytechnic institute and an institute of technology. One characteristic which differentiates a polytechnic institute from a liberal arts college is that the curricula in the institutes have been designed to prepare students for positions in engineering, applied science and agriculture upon graduation. The occupational objectives of the institutes' courses of training are thus more clearly defined than in the case with the liberal arts colleges. In the institutes a student spends as much as three-fourths to four-fifths of his time on technical and professional studies in the field of his specialization, and the remainder of the time is devoted to English and

ing and mining engineering. In addition to suggesting the subjects to be included in the curriculum, Greene also suggested the addition of other schools, emphasized the importance of general education and went into detail regarding the residences for faculty and students, buildings for instruction and

equipped to perform successfully in the fields for which they are being trained.

See Federal Security Agency, Office of Education, *Education Directory, Part 3, Higher Education (1950-51)*, *The True Idea of a Polytechnic Institute*, A Facsimile Reprint from the Report of Benjamin Franklin Greene, Director of Rensselaer Polytechnic Institute, 1840-1858 (1949).

(L. F. SH.)

POLYTONALITY, a comparatively recent addition to musical terminology, signifying the simultaneous employment of conflicting keys (See HARMONY, KEY)

POLYXENA, daughter of Priam and Hecuba. The shade of Achilles appeared to the returning Greeks in the Thracian Chersonese and demanded Polyxena, who was put to death on his tomb. As a prominent leader he claimed a prominent female prisoner for his share of the booty, as Agamemnon did Cassandra (q.v.). Hence, in Philostratus, Dictys and other late authors, the story of a romantic affection between Achilles and Polyxena.

POLYZOA or **BRYZOZA**, a group of animals in which the individuals bud and remain attached to each other to form colonies

FIG 1—ENTOPROCTA, SHOWING PEDICELLINA ON LEFT, AND LOXOSOMA ON RIGHT

which are sometimes planlike, suggesting the name Bryozoa, "moss animals." More frequently the colonies are encrusting and resemble the growth of lichens. The alternative name, Bryozoa, is used by all except British zoologists. Certain embryological and morphological characters suggest remote relationships to the Mollusca, Rotifera and especially to the Brachiopoda, with which latter group they have sometimes been classed as Molluscoidea. The tendency today is to separate them in a distinct phylum. They are pre-eminently marine, but there are a few fresh-water species. The individuals, or "zoecia," are seldom more than a millimeter in length, but the colonies, seldom more than an inch or so, may rarely reach more than a foot across. The body wall of the individual is usually well calcified, and fossil species are numerous as far back as the Ordovician.

It is probable that as their study advances they will take an increasingly important part in the determination of the geological age of strata. They may be defined as aquatic animals, forming colonies by budding, with ciliated tentacles which can be infolded or retracted into a depression of the body wall, with a U-shaped alimentary canal and a ganglion lying between the mouth and anus. Specific excretory organs are found in the Entoprocta alone.

Classification.—Sub-class I, Entoprocta—Lophophore (the part bearing the tentacles) circular, including both mouth and anus. Tentacles infolded, during retraction, into a "vestibule," which can be closed by a circular muscle. Body wall not calcified, body cavity absent. Definite excretory organs present. Reproductive organs continuous with ducts, which open into the vestibule. (See KAMPTOZOA as an alternative name.)

Loxosoma (fig 1), marine, is unique among the Polyzoa in the fact that the colony consists merely of a single individual, with

FIG 2—ECTOPROCTA Left, Gymnolomatia (Pallidocella), right, Phyllostomatia (Lophopus)

FROM THE QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE FIG. 3—CYCLOSTOMATA (CRISIA), AFTER HARMER

its system of buds, which are produced in two series, each bud breaking off on reaching maturity. It is of minute size, and nearly always occurs on other animals, Sponges, Polychaeta and Sipunculid worms, Ascidians or even Polyzoa. As in other Ectoprocta, the individual consists of a muscular stalk bearing a "calyx" or body, which contains the viscera and bears the tentacles. *Pedicularia* (fig 1), marine, has the individuals arranged in a linear series on an attached, narrow "stolon." The calyces are deciduous and can be regenerated, a process analogous to the formation of "brown bodies" in the Ectoprocta *Urnella*, a fresh water species.

Sub-class II Ectoprocta—Lophophore circular or shaped like a horseshoe (fig 2), including the mouth but not the anus. Tentacles retractile into a delicate, flexible "introvert" ("tentacle-sheath") of the body-wall (fig 6). Remnants of the body-wall membranous or calcified, the body-cavity spacious, containing the reproductive organs, which are not continuous with ducts. Specific excretory organs absent. Zoecia usually closely apposed to their neighbours, with which they are in organic connection by means of threads of living tissue, traversing "communication-pores" in the separating walls. There is naturally no evidence as to the anatomy of the two exclusively fossil Orders.

Tribe I Gymnolaemata. Lophophore circular (fig 2), without an "epistome" or lip. Body-cavities not continuous with one another, body-wall not muscular.

Order 1 Trepostomata. Fossil, Palaeozoic. Zoecia long, coherent, their cavity traversed by many transverse partitions, which become more numerous near the terminal orifice. Surface of colony with regularly distributed elevations or "monticules." The reference of these organisms, which include the Monticuliporidae, to the Polyzoa has been disputed, but the characters of the primary individual of the colony are in favour of this association.

Order 2 Cryptostomata. Fossil, Palaeozoic. Zoecia usually shorter than in the Trepostomata, sometimes with transverse partitions. Orifice at the bottom of a vestibular shaft, which may be traversed by diaphragms. This order, which includes the net-like Fenestellidae, has been regarded by palaeontologists as ancestral to the Cheilostomata.

Order 3 Cyclostomata. Zoecia elongated, prismatic or cylindrical (fig 3), with terminal, typically circular orifice, of the full width of the tubular part. The ovicells are modified, greatly enlarged zoecia, and, in the recent species investigated, contain numerous embryos, produced by the division of a single, primary embryo. The polypide is protruded with the aid of a "membranous sac," which surrounds it. The Cyclostomata are known from early Palaeozoic strata (Ordovician) onwards and are represented in the Cretaceous by specially numerous species, their highly calcareous zoecia being well preserved as fossils. They form a comparatively small proportion of the recent marine fauna, in which *Crista*, *Tubulipora*, *Idmonea*, *Entalopora*, *Hornera* and *Lichenopora* are represented by many species.

FIG 5.—AVICULARIUM AND OVICELL OF ENCRUSTING CHEILOSTOMATA

Order 4 Ctenostomata. Walls soft and uncalcified, the orifice being closed by a membranous "collar" (fig 4), with folded walls, which surrounds it. Encrusting or erect and broadly lobed, the zoecia connected with one another (*Alicynodinium*, *Flustrella*); or erect and delicate, the zoecia arising separately from a connecting stem (*Amathia*, *Bowerbankia*). The preceding are marine, but *Victorella* and *Paludicella*, belonging to the second group, occur in fresh water. Certain Palaeozoic fossils (*Rhopalomena*, *Vinella*) have been referred to this order.

Order 5 Cheilostomata. Much or little calcified, the orifice

closed by a chitinous operculum (fig 5). Polymorphism usually occurs, certain individuals being modified as "avicularia" or "vibracula." A prominent, globular "ovicell" is commonly found at the distal ("upper") end of the fertile zoecium, serving as an external brood-cavity in which an egg develops. This order is first known in the Mesozoic period (Jurassic), but its species become extremely numerous in the Cretaceous. In the Tertiary period,

FIG 6.—CHEILOSTOMATA ANASCA (ELECTRA), SHOWING ABOVE, POLYPIDE RETRACTED; BELOW, POLYPIDE EXPANDED

as at present, it is the dominant group of Polyzoa, chiefly marine but occasionally found in brackish water. Representative genera are *Membranopora*, *Flustra*, *Onychocella*, *Cestaria*, *Scrupocellaria*, *Bugula*, *Schizoporella*, *Retepora*, *Cellepora*.

Tribe II Phylactolaemata. Lophophore horseshoe-shaped (fig 2), except in *Fredericella*, the mouth guarded by a lip or "epistome." Body-wall muscular, uncalcified, the body-cavities continuous with one another. Reproduction sexual and by means of "statoblasts" (fig 12), internal buds protected by a chitinous shell. *Fredericella*, *Plumatella*, *Lophopus*, *Cristatella*. The colony can move slowly from place to place in the last two.

Structure of Ectoprocta.—The colony may assume several distinct forms. (a) Encrusting, the zoecia in close contact with one another, usually in a single layer, attached to a stone or seaweed by the basal surface, the orifices on the exposed or "frontal" surface, sometimes becoming multilaminar by the addition of new

FIG 7.—CHEILOSTOMATA ASCOPHORA, ILLUSTRATING THE METHOD OF PROTRUSION OF THE POLYPIDE

layers, each of which completely covers its predecessor, sealing the orifices; (b) erect, with broad lobes or branches, unilaminar or bilaminar, the zoecia correspondingly opening on one or both surfaces. Both these conditions are found in *Flustra* and its allies, in which there is little calcification and the branches are flexible. *Retepora* is a highly calcified unilaminar type, the branches of which form an elegant network. In other genera the branches are cylindrical, the orifices arranged all round the curved surfaces; (c) erect and more slender, resembling Hydroids, mostly bilaminar or with cylindrical branches, often with flexible joints; (d)

not rigidly attached, unilaminar, discoidal or conical

The zoecium of the Cheilostomata (fig 6) resembles a shallow box, having the "orifice" near the distal end, the one further from the base or commencement of the colony. The orifice is the external opening of a thin-walled "tentacle-sheath," really a flexible, uncalcified part of the body-wall, pushed into the body-cavity. The tentacles arise from the blind end of the retracted sheath, and these parts, with the U-shaped alimentary canal and the nerve-ganglion which lies between the mouth and anus, constitute the "polypide." Retraction of the tentacles takes place rapidly by means of retractor muscles, but protrusion is a more gradual process and is effected by "parietal muscles," the contraction of which increases the fluid pressure in the body-cavity and forces out the tentacles. Some part of the body-wall must accordingly be flexible, and in the division Anasca (fig 6) this is the whole or part of the frontal surface. In the Ascopora (fig 7) most of the frontal wall is calcified and rigid, but the part which lies on the proximal side of the operculum has been pushed in as a very delicate "compensation-sac," into the basal wall of which the parietal muscles are inserted. The contraction of these muscles dilates the sac, into which water enters from the outside, and the mechanism of protrusion is thus the same as in the Anasca. In the erect Ctenostomata the whole body-wall is flexible, and the parietal muscles produce their effect by passing from one part of it to another, across the body-cavity. In the Phylactolaemata the flexible body-wall is itself muscular. The calcareous Cyclostomata have a special, rather complicated arrangement for protrusion (see Borg, 1926).

Regeneration of the Polypide.—The duration of life of the polypide does not correspond with that of the zoecium, which has a succession of polypides. This curious fact is probably the result of the absence of definite excretory organs, the function of which seems to be performed largely by the stomach. The wall of this organ becomes charged with brown granules (probably excretory), and after a time the entire polypide degenerates, decreasing in size and ultimately becoming a small, rounded "brown body" (fig 8), which owes its colour to these granules. The substances of nutritive value have probably been absorbed, for future use, by the cells which surround the degenerating polypide. An internal polypide-bud is simultaneously developed, and in some species its stomach envelops the brown body, which is rejected with the faeces. In other cases the brown body remains as an inert mass in the zoecium, and the occurrence of several brown bodies indicates a corresponding number of degenerated polypides.

Polymorphism.—In the majority of Cheilostomata, certain zoecium have merely a vestige of a polypide, and the operculum, now known as the "mandible," and its muscles become modified for prehension. These units are known as "avicularia," from their resemblance to the head of a bird, in *Bugula* (fig 9) and other

FIG 8—CHEILOSTOMATA, REGENERATION OF THE POLYPIDE (CAR BASAL), AFTER HARMER

FIG 9—CHEILOSTOMATA, LEFT, STALKED AVICULARIA OF CORNU COPINA, RIGHT, OF BUGULA

genera in which they attain their highest development. The avicularia may be "vicarious," in series with the zoecia, which they may surpass in size, the mandibles being often much larger than the opercula (fig 10), or they are "adventitious" (fig 5), when they occur as appendages of ordinary zoecia. They are either "sessile," closely attached to the zoecia (fig 5) or stalked (fig 9), and they show a wide range of form, in different species. The "vibracula" (fig 11), which are found in a small number of Cheilostomata, have the operculum transformed into a long "seta," which sweeps through the water. In *Caberea* the vibracula of a branch have been observed to move in unison, but this is exceptional. The avicularia and vibracula appear to be defensive organs, and they doubtless ward off the attacks of some predacious animals. They probably prevent the overgrowth of the colony by encrusting organisms, by discouraging the attachment of larvae, and they may also serve to keep the colony clean, by dislodging foreign particles which might otherwise settle on it.

Reproduction.—The reproductive organs occur in the body-cavity in Ectoprocta, and organs of both sexes may be produced

by a single zoecium, simultaneously or successively. The colony seems to be generally bisexual, even when testes and ovaries are found in different zoecia. The ciliated larvae, in this group, rarely possess an alimentary canal. If this is present they are known as *Cyphonautes*, a common constituent of the floating fauna, especially of coastal waters. If it is absent the tissues are charged with nutritive yolk. In either case, the larva attaches itself, loses its larval organs and becomes the "ancestrula" or first zoecium of the colony, developing a polypide as an internal bud. The ancestrula buds off other zoecia, which repeat the process, thus building up the colony, and the zoecia develop their polypides in the same way as the ancestrula. In species with a *Cyphonautes* the egg develops in the water, but in most cases it develops in the parent colony. The characteristic "ovicells" of Cheilostomata (fig 5) are external brood-spaces into which the egg passes when it is laid, and are formed in part by the distal end of the fertile zoecium, but principally by the frontal surface of the succeeding zoecium. The egg passes from the body-cavity to the exterior (in the few cases where the process has been observed) through the "intertentacular organ," a ciliated tube between the bases of the two tentacles nearest the anus, or through a pore found in the same position. The Cheilostome ovicell nearly always contains a single egg, but in the Cyclostomata the ovicell (fig 3) contains very numerous embryos, which have been produced by the fission of a primary embryo, developed from an egg. In Phylactolaemata the polypide is produced by the larva while it is still free, several polypides occurring in *Cristatella* before the larva attaches itself. Another form of reproduction is found in this group, where the zoecium produces internal buds from the "funiculus," a cord connecting the blind end of the stomach with the body-wall. These special buds are known as "statoblasts" (fig 12), and each is protected by a strong chitinous shell, the outer part ("annulus") of which is modified as a ring containing air-

FIG 12—STATOBLASTS OF PHYLACTOLAEMATA, Above, *Plumatella*, below, *Pectinatella*

cells which enable the statoblast to float on the surface of the water when it becomes free. In temperate latitudes this happens in the late summer or autumn, and the statoblast develops into a new colony in the ensuing spring.

POMBAL, SEBASTIÃO JOSÉ DE CARVALHO E MELLO, MARQUESS OF (1699-1782), Portuguese statesman, was born at Soure near Pomba, on May 13, 1699. In 1739 he was sent as Portuguese ambassador to London, where he remained until 1745. He was then transferred to Vienna. In 1749 he took up the post of secretary of state for foreign affairs and war. Though he came into power only in his 51st year, without previous administrative experience, he was able to reorganize Portuguese education, finance, the army and the navy. He also built up new industries, promoted the development of Brazil and Macao, and expelled the Jesuits. His complete ascendancy over the mind of King Joseph dates from the time of the great Lisbon earthquake (Nov. 1, 1755). In Sept. 1770 he was made marquis of Pombal. Soon after the death of King Joseph, in 1777, Pombal was dismissed from office, and he was only saved from impeachment by the death of his bitterest opponent, the queen-mother, Mariana Victoria, in Jan. 1781. On Aug. 16, a royal decree forbade him to reside within 20 leagues of the court. He died at Pombal on May 8, 1782.

See in addition to the works dealing with the period 1750-77 and quoted under **PORTUGAL**, *History*, S. J. C. M. (Pombal), *Relação abreviada*, etc. (Paris, 1758), *Memoirs of the Court of Portugal*, etc. (1765), *Anecdotes du ministère de Pombal* (Warsaw, 1781), *Administration du marquis de Pombal* (4 vols., Amsterdam, 1787), *Curtas do marquis de Pombal* (3 vols., Lisbon, 1820-24), J. POMEGRANATE. Throughout the orient this fruit has since earliest times occupied a position of importance alongside the grape and the fig. It is produced by a bush or small tree, *Punica granatum*, only member of the family *Punicaceae*.

King Solomon possessed an orchard of pomegranates, and when the children of Israel, wandering in the wilderness, sighed for the abandoned comforts of Egypt, the cooling pomegranates were remembered longingly. Centuries later, the prophet Mohammed remarked sententiously "Eat the pomegranate, for it purges the system of envy and hatred." It will thus be seen that this fruit is of exceptional interest because of its historic background. While the pomegranate is considered to be indigenous in Persia and perhaps neighbouring countries, its cultivation long ago encircled the Mediterranean and extended through Arabia, Afghanistan and India. There is something in the character of the juicy subacid pomegranate which makes it particularly agreeable to inhabitants of hot arid regions—which are precisely those in which it attains its greatest perfection.

The ancient Semitic name *rimmon* was adopted by the Arabs as *rimman*, from which the Portuguese in turn formed *romão* or *roman*. From the early Roman names *malum punicum* (apple of Carthage) and *granatum* have come the modern botanical binomial and the common name *granada*, used in Spanish-speaking

countries.

The plant, which may attain 15 or 20 ft. in height, has elliptic to lanceolate bright green leaves about 3 in. long, and handsome axillary orange-red flowers borne toward the ends of the branchlets. The calyx is tubular, persistent, 5- to 7-lobed, the petals lanceolate, inserted between the calyx-lobes. The ovary is embedded in the calyx-tube and contains several locules in two series one above the other.

The fruit is the size of an orange and often larger, obscurely six-sided, with a smooth leathery skin which ranges from brownish yellow to red in colour. With

in it is divided into several cells, containing many thin transparent vesicles of reddish juicy pulp, each surrounding an angular elongated seed. A ripe pomegranate has a delightful subacid flavour.

Presumably the plant was introduced into the new world by the early Spanish colonists. It is commonly cultivated in gardens from the warmer parts of the United States to Chile. Small commercial plantings have been made in California. Though it will grow in a wide range of climates, good fruit is produced only where high temperatures and dry atmosphere accompany the ripening period. Deep, rather heavy loams are probably the best soils. Propagation is effected by seeds, cuttings and layers. The first-named can readily be grown, but choice varieties cannot be reproduced in this manner.

Commercial propagation is by hardwood cuttings 10 to 12 in. long, which can be rooted in the open ground.

The varieties of the pomegranate are numerous. Ibn-al-Awam, a Moor who wrote in the 13th century, described some ten which were grown in southern Spain at that time. The three leading ones which have been cultivated commercially in the United States are Wonderful, Paper-Shell and Spanish Ruby. There are also dwarf forms which produce fruit of no value but are grown for their handsome scarlet flowers. (W. Fo.)

POMERANIA (German, *Pommern*), a territory of Germany and a maritime province of Prussia, bounded on the north by the Baltic, on the west by Mecklenburg, on the south by Brandenburg, and on the east by Poland. Its area, with the border province (Grenzmark Posen-Westpreussen), is 14,870 sq mi. and the population in 1939 was 2,405,048, showing a density of 162 inhabitants to the square mile. Pomerania is one of the flattest parts of Germany, although east of the Oder it is traversed by a range of low hills, and there are also a few isolated eminences to the west. Off the west coast, which is very irregular, lie the islands of Rugen, Usedom and Wollin; the coast of Farther Pomerania is smooth in outline and is bordered with dunes, or sandbanks. Besides the Oder and its affluents, the chief of which are the Peene, the Ucker and the Inna, there are several smaller rivers flowing into the Baltic, a few of these rivers are navigable for ships, but the greater number only carry rafts.

The soil of Pomerania is for the most part thin and sandy, but patches of good land are found here and there. The principal crops are potatoes, rye and oats, but wheat and barley are grown in the more fertile districts, tobacco, flax, hops and beetroot are also cultivated. Horses for farmwork, sheep for both wool and mutton, cattle, pigs, geese (for flesh and feathers) are features of local agriculture. Owing to the long line of coast and the numerous lakes, fishing forms an important industry. Linen weaving is practised as a domestic industry. Shipbuilding is

POMEGRANATE (*PUNICA GRANATUM*), A. BRANCH WITH FLOWERS B. TRANSVERSE SECTION THROUGH FRUIT SHOWING SEEDS, C. YOUNG FRUIT

carried on at Stettin and at several places along the coast. The chief commercial ports of Pomerania are Stettin, Stralsund and Swinemünde. Education is provided for by a university at Greifswald and by numerous schools.

HISTORY.—In prehistoric times the southern coast of the Baltic seems to have been occupied by Celts, who afterwards made way for tribes of Teutonic stock. These in their turn were replaced about the end of the 5th century A.D. by Slavonic tribes, the Wilsa and the Pomoran. The name of Pomore, or Pommern, meaning "on the sea," was given to the district by the latter of the tribes about the time of Charlemagne. Originally it seems to have denoted the coast district between the Oder and the Vistula. Afterwards Pomerania extended much farther to the west, while being correspondingly curtailed on the east, and a distinction was made between Slavonia, or modern Pomerania, and Pomerellen. The latter, corresponding substantially to the so-called Polish corridor, remained subject to Poland until 1309, when it was divided between Brandenburg and Teutonic Order.

The history of Pomerania, as distinct from that of Pomerellen, consists mainly in a succession of partitions and in constant hostilities with the elector of Brandenburg, who claimed to be its immediate feudal superior. During the Thirty Years' War Pomerania was devastated and by the peace of Westphalia the elector of Brandenburg acquired eastern Pomerania (Hinterpommern), and the western part (Vorpommern) was awarded to Sweden. In 1720 Swedish Pomerania was curtailed by extensive concessions to Prussia, but the district to the west of the Peene remained in the possession of Sweden until the general European settlement of 1815. Then Sweden assigned her German possessions to Denmark in exchange for Norway, whereupon Prussia, partly by purchase and partly by the cession of the duchy of Lauenburg, finally succeeded in uniting the whole of Pomerania under her rule.

See F. W. Barthold, *Geschichte von Rugen und Pommern* (Hamburg, 1830-45); the *Codex Pomeranicus diplomaticus*, edited by K. F. W. Hasselbach and J. G. L. Kossigarten (Greifswald, 1862); H. Berghaus, *Landbuch des Herzogtums Pommern* (1865-70); K. Müll, *Pommersche Geschichte* (Stettin, 1895); J. Bugenhagen, *Pomerania*, edited by O. Henemann (Stettin, 1900); M. Wehtmann, *Geschichte von Pommern* (Gotha 1904-6).

POMFRET, JOHN (1667-1702), English poet, born at Luton, became rector of Maulden, Bedfordshire, in 1695, and of Millbrook in the same county in 1702. His poems were printed in Johnson's *English Poets* (1779, vol. xxi).

POMMER or **BOMBARD**, the alto, tenor and basses of the shawm or schalmey family, and the forerunners respectively of the cor-anglia, bassoon or fagotto, and double bassoon or contrabagetto. (See **BASSOON** and **OBOE**.)

POMO. This group of American Indians, speaking seven dialects of Hoka (q.v.) Ingego, on Russian river and Clear lake, California, is noted for its basketry, which is perhaps the finest and most varied made on the continent. The general culture was central Californian as typified by the Maidu (q.v.). The Pomo have decreased from about 8,000 to 800. See S. A. Barrett, *Unw. Calif. Publ. Am. Arch. Ethn.*, vols. vi, vii (1908); E. W. Gifford, *ibid.*, vol. xviii (1926); E. M. Loeb, *ibid.*, xix (1926).

POMONA, an old Italian goddess of fruit and gardens. Pomona had a special priest at Rome, the *flamen Pomonalis*, and a sacred grove near Ostia, called the Pomonal.

POMONA, a city of Los Angeles county, California, U.S.A., 30 mi E. of Los Angeles, at an altitude of 850 feet. It is served by the Santa Fe, the Southern Pacific, and Union Pacific railways, and by motor coach lines. The population was 35,405 in 1950, and 42,175 in 1955 by the federal census. It is one of the principal shipping points in the state for citrus fruit and walnuts. At Claremont, 2 mi N. is Pomona college, incorporated under the auspices of the Congregational churches of Southern California in 1887. Pomona was founded by fruit-growers in 1875 and was chartered as a city in 1875.

POMONA or **MAINLAND**, central and largest island of the Orkneys, Scotland. Pop. (1931) 13,357. It is 25 mi long from N.W. to S.E. and 5 mi broad from E. to W. Area 150 sq. mi. It has the sea cliffs of the Great North Face, the highest point of the island.

and on the S. by Scapa Flow, the land is less than 2 mi across. The west coast is almost unbroken, the bays of Birsay and Skall being the only bays of any importance, but the east and south shores are much indented. The highest points of the watershed from Costa Head to the Scapa shore are Mildoe to the north-east of Ibister and Wideford Hill to the west of Kirkwall. There are also a few eminences towards the southwest, Ward Hill (880 ft.) in the parish of Orplur being the highest peak in the island. There are numerous lakes, some of considerable size and most of them abounding with trout. Kirkwall, the capital of the Orkneys, and Stromness are the only towns.

In Harray, the only parish in the Orkneys not touched at some point by the sea, Norse customs have survived longer than elsewhere in the group save in North Ronaldshay.

The antiquities of Pomona are of great interest. The examples of Pictish remains include *brochs*, chambered mounds and weens or underground dwellings afterwards roofed in. North-east of Stromness, and within a mile of the stone circles of Stennes, stands the great barrow or chambered mound of Maeshowe. The tumulus has the form of a blunted cone, 300 ft. in circumference, and at a distance of 90 ft. from its base is encircled by a moat. The ground-plan shows that it was entered from the west by a passage, which led to a central apartment, the walls of which ended in a beehive roof. The barrow is variously ascribed to the Stone Age and to 10th century Norsemen.

The stone circles forming the Ring of Brogar and the Ring of Stennes lie 4½ mi N.E. of Stromness. The Ring of Brogar, once known as the Temple of the Sun, stands on a raised circular platform of turf, surrounded by a moat and a grassy rampart. The ring originally comprised 60 stones, varying from 9 to 14 ft. in height, set up at intervals of 17 ft. Only 13 are now erect. The Ring of Stennes—the Temple of the Moon of local tradition—is of similar construction. The Stone of Odin, the great monolith, pierced by a hole at a height of 5 ft. from the ground, which figures so prominently in Scott's *Pirate*, stood 150 yd. to the north of the Ring of Stennes.

POMORZE or **POMERANIA** (i.e., "along the sea"), a province of Poland, bounded on the N. by the Baltic, on the E. by East Prussia, on the S. by the provinces of Warsaw and Poznan, on the W. by Germany. Area, 7,733 sq. mi., pop. (1946), 1,406,500. Germany seized the province in 1939.

Pomorze, which has been, in modern times, very incorrectly called West Prussia and the "Polish corridor," consists of two quite distinct units. West of the Vistula is eastern Pomerania, which was colonized by Poland when West Pomerania became a German colony, was seized by the Teutonic Order in 1309, recovered by Poland in 1466 and held till 1773, when it was seized by Prussia. East of the Vistula is the territory of Chelmino or Kulm, a Polish border province ceded to the Teutonic Order in the 13th century and recovered in 1466. Both these territories remained mainly Polish despite the colonizing efforts of the Prussian government in the 19th century. Danzig, which had a German majority, was made into a Free State by the treaty of Versailles, mixed areas decided their future by a plebiscite, and the remaining territory was reunited to the other parts of Poland, to which it was essential as the only outlet of Poland on the sea. The Prussian rule of over 140 years left a German minority, forming 11% of the population, the Poles formed 89% (1935).

Pomorze is mainly an agricultural country, its industries depending on agriculture. Together with Poznan, it was formerly one of the chief sources of foodstuffs for Germany. The peasant is highly educated and well organized, the agricultural co-operative societies having been a great economic and national asset. Forestry is well organized in the great Tuchola forest. Distilling, brewing and sugar refining are important industries. The province is famous for stockbreeding, having a greater number of sheep per acre than any other part of Poland. The fisheries are extensive, but not well organized. The province is well served by railways. A constantly growing traffic by rail and river descends to Danzig and the new port of Gdynia. The chief towns are Gdynia (pop. 103,000 in 1950), Torun (pop. 68,085 in 1946),

Starograd and Świecie in the west Pomorze, tactically difficult to defend, was rapidly conquered by Germany in World War II.

POMPADOUR, JEANNE ANTOINETTE POISSON LE NORMANT D'ÉTOILES, MARQUISE DE (1721-1764), mistress of Louis XV, was born in Paris on Dec. 29, 1721, and baptized as the legitimate daughter of François Poisson, an officer in the household of the duke of Orleans, and his wife, Madeleine de la Motte, in the church of St. Eustache, but she was educated at the charge of a wealthy financier and farmer-general of the revenues, Le Normant de Tournemire. He declared her "un morceau de roi," and specially educated her to be a king's mistress. This idea was confirmed in her childish mind by the prophecy of an old woman, whom in after days she personated for the correctness of her prediction. In 1741 she was married to a nephew of her protector and guardian, Le Normant d'Étoiles, who was passionately in love with her, and she soon became a queen of fashion. The king met her at a ball given by the city to the dauphin in 1744, and he was immediately subjugated. She at once gave up her husband, and in 1745 was established at Versailles as "maîtresse en titre." Louis XV bought her the estate of Pompadour, from which she took her title of marquise (raised in 1752 to that of duchess).

She was hardly established firmly in power before she began to mix in politics. Knowing that the French people of that time were ruled by the literary kings of the time, she paid court to them, and tried to play the part of a Maecenas. Voltaire was her poet in chief, and the founder of the physiocrats, Quesnay, was her physician. The command of the political situation passed entirely into her hands, she it was who brought Belle-Isle into office with his vigorous policy, she corresponded regularly with the generals of the armies in the field, as her letters to the Comte de Clermont prove, and she introduced the Abbé de Bernis into the ministry in order to effect a very great alteration of French politics in 1756. The continuous policy of France since the days of Richelieu had been to weaken the house of Austria by alliances in Germany, but Mme de Pompadour changed this hereditary policy for the alliance with Austria which brought on the Seven Years' War, with all its disasters.

But it was to internal politics that this remarkable woman paid most attention. She made herself indispensable to Louis. She died on April 15, 1764, at the age of forty-two.

See Capéfigue, *Madame la marquise de Pompadour* (1858), E and J de Goncourt, *Les Maîtresses de Louis XV*, vol. II (1880), and Campardon, *Madame de Pompadour et la cour de Louis XV. au milieu du dix-huitième siècle* (1867). Far more valuable are Malassus's two volumes of correspondence, *Correspondance de Madame de Pompadour avec son père M. Poisson, et son frère M. de Vanilleux*, etc. (1878), and Bonhomme, *Madame de Pompadour, général d'armée* (1880), containing her letters to the Comte de Clermont. See also P. de Nolhac, *La Marquise de Pompadour* (1903).

POMPEII, an ancient town of Campania, Italy, near the river Sarnus, almost at the foot of Mt. Vesuvius. Its foundation was ascribed by Greek tradition to Heracles, in common with the neighbouring city of Herculaneum, but it was not a Greek colony. Strabo, in whose time it was a populous and flourishing place, tells us that it was first occupied by the Oscans, afterwards by the Tyrrhenians (i.e., Etruscans), to whom it probably owes its rectangular ground plan, and Pelasgians, and lastly, by the Samnites. (See CAMPANIA.) No doubt, Pompeii shared the fate of the neighbouring cities, and afterwards passed in common with them under the yoke of Rome. But its name is only mentioned incidentally during the wars of the Romans with the Samnites and Campanians only when a Roman fleet landed near Pompeii in 300 B.C. and made an unsuccessful marauding expedition up the river valley as far as Nuceria. At a later period, however, it took a prominent part in the Social War (91-89 B.C.), when it withstood a long siege by Sulla, and was one of the last cities of Campania that were reduced by the Roman arms. The inhabitants were admitted to the Roman franchise, but a military colony was settled in their territory in 80 B.C. by Sulla (*Colonia Cornelia Veneria Pompeianorum*), and the whole population was rapidly Romanized. Before the close of the republic many Roman nobles acquired villas in the neighbourhood, among them Cicero, whose

letters abound with allusions to his Pompeian villa. The same fashion continued under the empire, and during the first century of the Christian era, Pompeii had become a flourishing place with a considerable population. In A.D. 59 a tumult took place in the amphitheatre between the citizens and visitors from Nuceria. Many were killed and wounded on both sides. The Pompeians were punished for this violent outbreak by the prohibition of all theatrical exhibitions for ten years. A painting on the walls of one of the houses represents this event.

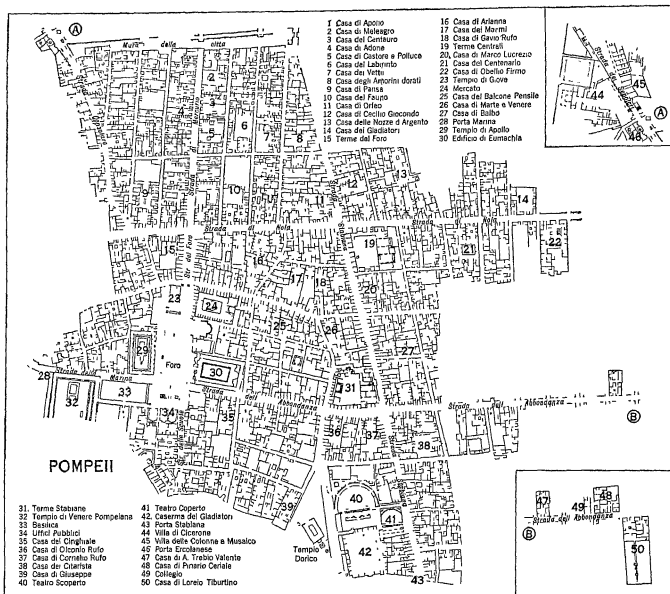

Four years afterwards (A.D. 63) an earthquake vented its force especially upon Pompeii, a large part of which, including most of the public buildings, was either destroyed or so seriously damaged as to require to be rebuilt. The inhabitants were still actively engaged in repairing and restoring it, when the whole city was overwhelmed by the great eruption of Vesuvius (79 A.D.). Pompeii was merely covered with a bed of lighter substances, cinders, small stones and ashes, which fell in a dry state, while at Herculaneum the same substances, being drenched with water, hardened into a sort of tufa, which in places is 65 ft. deep. The whole of this superincumbent mass, attaining to an average thickness of from 18 to 20 ft., was the product of one eruption, though the materials may be divided generally into two distinct strata, the one consisting principally of cinders and small volcanic stones (called in Italian *lapilli*), and the other and uppermost layer of fine white ash, often consolidated by the action of water from above so as to take the moulds of objects contained in it (such as dead bodies, woodwork, etc.), like clay or plaster of Paris. It was found impossible to rebuild the town, and its territory was joined to that of Nola. But the survivors returned to the spot, and by digging down and tunnelling were able to remove all the objects of value, even the marble facing slabs of the large buildings.

In the middle ages, however, the very site was forgotten. Ruins and inscriptions were found by the architect Domenico Fontana in making an underground aqueduct across the site in 1594-1600, but only in 1748 a more careful inspection of this channel revealed the fact that beneath there lay entombed ruins far more accessible than those of Herculaneum. Only in 1763 systematic excavations were begun, the work, which had received a vigorous stimulus during the period of the French government (1806-14), was prosecuted under the Bourbon kings (1815-61). Since 1861 it has been carried on under the Italian government on a system devised by G. Fiorelli, according to which the town is for convenience divided into 6 or 9 regions, which are subdivided into *insulae* (blocks), the gates, streets and houses being also named for convenience, though often incorrectly.

The town was situated on rising ground less than a mile from the foot of Vesuvius. This eminence is itself due to an outflow of lava from that mountain, during an eruption in prehistoric times, for we know that Vesuvius had been quiescent ever since the Greek settlements in this part of Italy.

The area occupied by the ancient city was of an irregular oval form, and about 2 m. in circumference. It was surrounded by a wall, which is still preserved for more than two-thirds of its extent, but no traces of this are found on the side towards the sea, and there is no doubt that on this side it had been already demolished in ancient times, so as to give room for the free extension of houses and other buildings in that direction. It consisted of two parallel stone walls with buttresses, about 15 ft. apart and 28 in. thick, the intervening space being filled with earth, and there being an embankment on the inner side. These walls are strengthened at intervals by numerous towers, occupying the full width of the wall. They appear to have been added at a later period, probably that of the Social War. Similar evidences of the addition of subsequent defences are to be traced also in the case of the gates, of which five have been cleared, while at least one (and perhaps three) more are unexcavated.

The general plan of the town is very regular, the streets being generally straight, and crossing one another at right angles or nearly so. But exceptions are found in the south-west corner, where a small irregular group of streets represents the original Oscan settlement, and on the north-west in the street

leading from the Porta Ercolanese (gate of Herculaneum) to the forum, which, though it must have been one of the principal thoroughfares in the city, was crooked and irregular, as well as very narrow, in places not exceeding 12 to 14 ft. in width. Another exception is to be found in the Strada Stabiana (Stabian Street) or Cardo, which, owing to the existence of a natural depression which affects also the line of the street just east of it, is not parallel to the other north and south streets. The other main streets are in some cases broader, but rarely exceed 20 ft. in width, and the broadest is about 32 ft., while the back streets running parallel to the main lines are only about 14 ft. (the standard width of a Roman highroad). They are uniformly paved with large polygonal blocks of hard basaltic lava, fitted very closely together, though now in many cases marked with deep ruts from the passage of vehicles in ancient times. They are also in all cases bordered by raised footways on both sides, paved in a similar manner, and for the convenience of foot-passengers, these are connected from place to place by stepping-stones raised above the level of the carriage-way. The careful investigation in recent years of the buildings in the eastern portion of the Strada dell'Abbondanza has shown that previous conceptions of the appearance of the exterior of the houses were entirely erroneous. The upper stories were diversified by balconies, open loggias, colonnades, etc., while the lower portions of the façades were painted, often with scenes of considerable interest. The streets were also

diversified by fountains, small water-towers and shrines.

The first-mentioned of the two principal streets was crossed, a little before it reached the forum, by the street which led directly to the gate of Nola (Strada delle Terme, della Fortuna, and di Nola). Parallel to this last to the south is a street which runs from the Porta Marina through the forum, and then, with a slight turn, to the Sarno gate, thus traversing the whole area of the city from east to west (Via Marina, Strada dell'Abbondanza, Strada dei Dandumeni). These two east and west streets are the two *decumani*.

The population of Pompeii was mixed, both Oscan and Greek inscriptions are still found up to the last, and evidences of the presence of Jews are not lacking—such as a wall-painting, probably representing the Judgment of Solomon, and a scratched inscription on a wall, "Sodoma, Gomora." From the number of skeletons discovered, about 2,000 persons may have perished in the city itself in the eruption of A.D. 79.

The whole portion of the city which lies to the west of the Strada Stabiana, towards the forum and the sea, has been completely excavated. It is over one-half of the whole extent, and the most important portion, inasmuch as it includes the forum, with the temples and public buildings adjacent to it, the *thermae*, theatres, etc. The greater part of that on the other side of the Strada Stabiana remains still unexplored, with the exception of the amphitheatre, a small space in its immediate

neighbourhood and the buildings on each side of the Strada dell' Abbondanza and the Strada di Nola.

The forum at Pompeii was the centre of the life and movement of the city. Hence it was surrounded on all sides by public buildings or edifices of a commanding character. It was not, however, of large size, only 467 ft in length by 126 in breadth (excluding the colonnades). The nature of its pavement, composed of broad flags of travertine, into which was let an inscription in large bronze letters, shows that it was only intended for foot-passengers. It was adorned with numerous statues. It was surrounded on three sides by a series of porticos supported on columns, and these porticos were originally surmounted by an upper storey, traces of the staircases leading to which still remain. Both this portico and the adjacent buildings were undergoing a process of restoration after the earthquake of 63, involving material changes in the original arrangements, which was still incomplete at the time of their final destruction. The north end of the forum, where alone the portico is wanting, is occupied in great part by the imposing temple of Jupiter, Juno and Minerva, or Capitulum. It was raised on a *podium* 10 ft high, and had a portico with six Corinthian columns in front. This magnificent edifice had, however, been evidently overthrown by the earthquake of 63, and is in its present condition a mere ruin, the rebuilding of which had not been begun at the time of the eruption. On each side of it were two arches, affording an entrance into the forum, but capable of being closed by gates. On the east side of the forum were four public edifices. The first (from the north), is a *macellum* or meat-market, consisting of a rectangular court surrounded by a colonnade, with a twelve-sided roofed building (*tholos*) in the centre. On the south side were shops, and in the centre of the east side a chapel for the worship of the imperial house. Next to this comes the sanctuary of the Lares of the city, a square room with a large apse, and beyond this a small temple. Beyond this again, bounded on the south by the Strada dell' Abbondanza, is a large and spacious cloth-exchange, erected by a priestess named Eumachia. It is an open court, oblong, surrounded on all four sides by a colonnade, in front is a portico facing the forum, and on the other three sides there is a corridor behind the colonnade with windows opening on it. On the south side of the Strada dell' Abbondanza was the Comitium. At the south end of the forum are three halls side by side, similar in plan with a common façade—the central one, the curia or council chamber, the others the offices respectively of the duumvirs and aediles, the principal officials of the city, while the greater part of the west side is occupied by two large buildings—a basilica, which is the largest edifice in Pompeii, and the temple of Apollo, which presents its side to the forum. The former, a building of the 2nd cent. B.C., was an oblong edifice divided by columns into a central hall and a corridor running round all the four sides with a tribunal opposite the main entrance, and, unlike the usual basilicae, it had, instead of a clerestory, openings in the walls of the corridor through which light was admitted, it being almost as lofty as the nave. The temple was an extensive edifice, having a comparatively small *cella*, raised upon a *podium*, and standing in the midst of a wide space surrounded by a portico of columns, outside which again is a wall, bounding the sacred enclosure. Between this temple and the basilica the Via Marina leads off direct to the Porta Marina.

The remains of five other temples have been discovered. The most interesting, though the least perfect, is not only by far the most ancient edifice in Pompeii, but a true Greek temple (6th century B.C.). Unfortunately only the foundation and a few Doric capitals and other architectural fragments remain; they were coated with brightly painted stucco. The reverence attached to it in later periods is shown by its being left standing in the midst of a triangular space adjoining the great theatre, which is surrounded by a portico, so as to constitute a kind of forum (the so-called Foro Triangolare). Not far off, and to the north of the great theatre, stood a small temple, dedicated to Isis, rebuilt after the ruinous earthquake of 63. It is interesting as the only temple of Isis that has come down to us in a good state of preservation. The decorations were of somewhat gaudy stucco. The

plan is curious, the internal arrangements being adapted for the performance of the peculiar rites of this deity. Close to this was the small temple of Zeus Melchus. The temple of the Fortune of Augustus (Fortuna Augusta), which stood north of the Forum, suffered very severely from the earthquake, but we learn from existing remains that its walls were covered with slabs of marble, and that the columns of the portico were of the same material. The fifth temple, that of Venus Pompeiana, to the west of the basilica, was in process of rebuilding at the time of the eruption. Before the earthquake of 63 it must have been the largest temple of the whole city. It was surrounded by a large colonnade, and the number of marble columns in the whole block has been reckoned at 296. Venus was the protectress of the young men of Pompeii, who had formed a society for gymnastics and other sports. They met in a hall (the *Schola Iuventutis Pompeianae*) in the Strada dell' Abbondanza.

All the temples above described, except that ascribed to Hercules, which was approached by steps on all four sides, agree in being raised on an elevated *podium* or basement—an arrangement usual with all similar buildings of Roman date. Among the other public buildings, the most conspicuous are the theatres, of which there were two, placed, as was usual in Greek towns, in close juxtaposition with one another. The largest of these, which was partly excavated in the side of the hill, was in great part cased with marble, with seats of the same material for about 5,000 spectators. It was erected in Roman times by two members of the same family, M. Holconius Rufus and M. Holconius Celer, both of whom held important municipal offices at Pompeii during the reign of Augustus. Their work was only a reconstruction of a more ancient edifice (probably 5th cent. B.C.), while its first alteration belongs to the "tufa" period, and three other periods in its history can be traced. The smaller theatre (for 1,500 spectators) was erected by two magistrates specially appointed for the purpose by the decuriones of the city, soon after the establishment of the Roman colony under Sulla. It was permanently covered.

Adjoining the theatres is a large rectangular enclosure, surrounded by a portico, at first the colonnade connected with the theatres, and converted, about the time of Nero, into the barracks of the gladiators. Remains of armour and weapons were found in some of the rooms, and in one, traces of the stocks used to confine insubordinate gladiators with three skeletons in them (63 were found in the whole building). The amphitheatre was erected by the same two magistrates who built the smaller theatre, C. Quinctius Valgus and M. Porcius when no permanent edifice of a similar kind had yet been erected in Rome itself, and is indeed the oldest structure of the kind known to us. It is in great part excavated in the surface of the hill, instead of the seats being raised on arches. Nor are its dimensions (460 by 345 ft.) such as to place it in the first rank, nor are there any underground chambers below the arena. The seating capacity was about 20,000 (for illustration see AMPHITHEATRE).

Among the more important public buildings of Pompeii were the public baths (*thermae*). Three different establishments of this character have been discovered, the first, the baths near the forum, though the smallest of the three, is in some respects the most complete and so well preserved that we trace without difficulty all the separate apartments described to us by Roman authors—the *apodyterium*, *frigidarium*, *tepidarium*, *calidarium*, and so on. (See BATHS.) The greater *thermae* (the so-called "Stabian" baths), which were originally built in the 2nd century B.C., and repaired about 80 B.C., are more extensive and combine a palaestra in the centre and other apartments for exercise or recreation. An inscription records the repair and restoration of the edifice after the earthquake of 63. These two establishments were inadequate to supply the wants of the inhabitants, and a third edifice, the so-called central baths, at the corner of the Strada Stabiana and the Strada di Nola, but on a still more extensive scale, intended for men only, was in course of construction in A.D. 79.

Far more interesting is the insight afforded us by the numerous private houses and shops into the ordinary life and habits of the population of an ancient town. The houses at Pompeii are gen-

erally low, rarely exceeding two storeys in height, the upper storey is generally of a slight construction, and occupied by small rooms, serving as garrets, or sleeping places for slaves. From the mode of destruction of the city these upper floors were in most cases crushed in and destroyed. The principal living rooms, as well as those intended for the reception of guests or clients, were all on the ground floor, the centre being formed by the *atrium*, or hall, which had an opening in the centre—the *compluvium*, so-called because the rain from the roofs was collected by it and fell into a basin (the *impluvium*). In the larger houses it was often surrounded with columns. Into this opened other rooms, the entrances to which, rarely protected by doors, were only closed by curtains. At the back was a garden. Later, under Greek influences, a peristyle with rooms took the place of the garden.

All the apartments and arrangements described by Vitruvius and other ancient writers may be readily traced in the houses of Pompeii, and in many instances these have for the first time enabled us to understand the technical terms and details transmitted to us by Latin authors. We must not, however, hastily assume that the examples thus preserved to us by a singular accident are to be taken as representing the style of building in all the Roman and Italian towns—in fact, the excavations at Ostia (*qv*) have shown us the contrary. We know from Cicero that Capua was remarkable for its broad streets and widespread buildings, and it is probable that the Campanian towns in general partook of the same character. At Pompeii indeed the streets were not wide, but they were straight and regular, and the houses of the better class occupied considerable spaces, presenting in this respect no doubt a striking contrast, not only with those of Rome itself, but with those of many other Italian towns, where the buildings would necessarily be huddled together from the circumstances of their position. Even at Pompeii itself, on the south side of the city, where the ground slopes somewhat steeply towards the sea, houses are found which consisted of three storeys or more, and with the inner walls painted black (with white designs on them) owing to the brilliancy of the light.

The excavations have provided examples of houses of every description, from the humble dwelling-place of the artisan or proletarian, with only three or four small rooms, to the stately mansions of Sallust, of the Faun, of the Golden Cupids, of the Silver Wedding, of the Vettii, of Pansa, etc.—the last of which is among the most regular in plan. But the general similarity in their plan and arrangement is very striking, and in all those that rise above a very humble class the leading divisions of the interior, the *atrium*, *tablinum*, *peristyle*, etc., may be traced with unflinching regularity. In all the more considerable houses in Pompeii the front, where it faces one of the principal streets, is occupied with shops, usually of small size, and without any communication with the interior of the mansion. In general the shop had a very small apartment behind it, and probably in most cases a sleeping chamber above it, reached by a staircase. The front of the shop was open to the street, but was capable of being closed with wooden shutters. Not only have the shops of silversmiths been recognized by the precious objects of that metal found in them, but large quantities of fruits of various kinds preserved in glass vessels, various descriptions of corn and pulse, loaves of bread, moulds for pastry, fishing-nets and many other objects too numerous to mention, have been found in such a condition as to be identified without difficulty. Inns and wine-shops appear to have been numerous, one of the latter we can see to have been a *thermopolium*, where hot drinks were sold. Bakers' shops are also frequent, though arrangements for grinding and baking appear to have formed part of every large family establishment. In other cases, however, these were on a larger scale, provided with numerous querns or hand-mills of the well-known form, evidently intended for public supply. Other establishments on a large scale were *fulonicae* (fullers' shops), where all the details of the business were illustrated by paintings still visible on the walls. Dyers' shops, a tannery and a shop where colours were ground and manufactured are of special interest, as is also the house of a surgeon, where numerous surgical instruments were found, some of them of a very ingenious and elaborate description, but all made of

bronze. A blacksmith's shop was also found, with many tools that had been brought in for repair. Here were discovered the remains of a *groma*, the instrument used by Roman land-surveyors, which has been successfully reconstructed (Della Corte in *Monumenti dei Lincei*, 1922). Another curious discovery was that of the abode of a sculptor, containing his tools, as well as blocks of marble and half-finished statues.

Of the numerous works of art discovered in the course of the excavations the statues and large works of sculpture, whether in marble or bronze, are inferior to those found at Herculaneum, but some of the bronze statuettes are of exquisite workmanship, while the profusion of ornamental works and objects in bronze and the elegance of their design, as well as the finished beauty of their execution, are such as to excite the utmost admiration—more especially when it is considered that these are the casual results of the examination of a second-rate provincial town, which had, further, been ransacked for valuables (as Herculaneum had not) after the eruption of 79. The same impression is produced in a still higher degree by the paintings with which the walls of the private houses, as well as those of the temples and other public buildings, are adorned, and which are not merely of a decorative character, but in many instances present us with elaborate compositions of figures, historical and mythological scenes, as well as representations of the ordinary life and manners of the people, which are full of interest to us, though often of inferior artistic execution. It has until lately been the practice to remove these to the museum at Naples; but the present tendency is to leave them (and even the movable objects found in the houses) *in situ* with all due precautions as to their preservation, which adds immensely to the interest of the houses, indeed, with the help of careful restoration, their original condition is in large measure reproduced. In some cases it has even been possible to recover the original arrangement of the garden beds, and to replant them accordingly, thus giving an appropriate framework to the statues, etc., with which the gardens were decorated, and which have been found *in situ*. The same character of elaborate decoration, guided almost uniformly by good taste and artistic feeling, is displayed in the mosaic pavements, which in all but the humblest class of houses frequently form the ornament of their floors. One of these, in the House of the Faun, well known as the battle of Alexander, presents us with the most striking specimen of artistic composition that has been preserved to us from antiquity.

The architecture of Pompeii presents in general a transitional character from the pure Greek style to that of the Roman Empire. The temples (as already observed) have always the Roman peculiarity of being raised on a *podium* of considerable elevation, and the same characteristic is found in most of the other public buildings. All the three orders of Greek architecture—the Doric, Ionic and Corinthian—are found freely employed in the various edifices of the city, but rarely in strict accordance with the rules of art in their proportions and details, while the private houses naturally exhibit still more deviation and irregularity. In many of these indeed we find varieties in the ornamentation, and even in such leading features as the capitals of the columns, which remind one rather of the vagaries of mediæval architecture than of the strict rules of Vitruvius or the regularity of Greek edifices. One practice which is especially prevalent, so as to strike every casual visitor, and dates from the early years of the empire, is that of filling up the flutings of the columns for about one-third of their height with a thick coat of stucco, so as to give them the appearance of being smooth columns without flutings below. The architecture of Pompeii suffers from the inferior quality of the materials generally employed. No good building stone was at hand; and the public as well as private edifices were constructed either of volcanic tufa, or lava, or Sarno limestone, or brick (the latter only used for the corners of walls). In the private houses even the columns are mostly of brick, covered merely with a coat of stucco. Marble was sparingly employed.

These materials are used in several different styles of construction belonging to the six different periods which Mau traces in the architectural history of Pompeii.

1. That of the Doric temple in the Foro Triangolare (6th cen-

tury B.C.) and an old column built into a house in Region VI, Insula 5, also of the older parts of the city walls—date uncertain (Sarno limestone and grey tufa)

2 That of the limestone atriums (outer walls of the houses of ashlar-work of Sarno limestone, inner walls with framework of limestone blocks, filled in with small pieces of limestone) Date before 200 B.C.

3 Grey tufa period, ashlar masonry of tufa, coated with fine white stucco, rubble work of lava. The artistic character is still Greek, and the period coincides with the first (incrustation) style of mural decoration, which (coming from Asia Minor or Greece perhaps by way of Sicily) aimed at the imitation in stucco of the appearance of a wall veneered with coloured marbles. No wall paintings exist, but there are often fine floor mosaics. To this belong a number of private houses (e.g., the House of the Faun), and the colonnade round the forum, the basilica, the temples of Apollo and Jupiter, the large theatre with the colonnades of the Foro Triangolare, and the barracks of the gladiators, the Stabian baths, the Palaestra, the exterior of the Porta Marina, and the interior of the other gates—all the public buildings indeed (except the Doric temple mentioned under [1], which does not belong to the time of the Roman colony). Date, end of 2nd and 2nd century B.C.

4 The "quasi-reticulate" period—walling faced with masonry not yet quite so regular as *opus reticulatum*, and with brick quoins, coinciding with the second period of decoration (the architectural, partly imitating marble like the first style, but without relief, and by colour only, and partly making use of architectural designs framing pictorial scenes, which are conceived as seen through openings). It is represented by the small theatre and the amphitheatre, the baths near the forum, the temple of Zeus Melchior, the Comitium and the original temple of Isis, but only a few private houses. This style probably owes much to Hellenistic theatrical decoration. Date, from 80 B.C. until nearly the end of the Republic.

5 The period from the last decades of the Republic to the earthquake of A.D. 63. No homogeneous series of buildings—we find various styles of construction (quasi-reticulate, *opus reticulatum* of tufa with stone quoins, of the time of Augustus, *opus reticulatum* with brick quoins or with tumbled stone and brick quoins, a little later), and three styles of wall decoration fall within its limits: the later stage of the second, already mentioned, the third or ornate, with its freer use of ornament and its introduction of designs which suggest an Egyptian origin (originating in the time of Augustus), and the fourth or intricate, with a return to architectural forms, dating from about A.D. 50. Marble first appears as a building material in the temple of Fortuna Augusta (c. 30 B.C.).

6 The period from the earthquake of A.D. 63 to the final destruction of the city, the buildings of which can easily be recognized. The only wholly new edifice of any importance is the central baths.

Outside the Porta Ercolanese, or gate leading to Herculaneum, is found a house of a different character from all the others, undoubtedly a large villa, its remains are of interest as aiding us in understanding the description of ancient authors, such as Vitruvius and Pliny, of the numerous appurtenances frequently annexed to houses of this description.

In the cellar of this villa were discovered no less than twenty skeletons, and fourteen in other parts of the house. Almost all the skeletons and remains of bodies found in the city were discovered in similar situations, in cellars or underground apartments—those who had sought refuge in flight having apparently for the most part escaped from destruction, or having perished under circumstances where their bodies were easily recovered by the survivors. It has been found possible in many cases to take casts of the bodies found.

An interesting farm-house (few examples have been so far discovered in Italy) is that at Boscoreale excavated in 1893-94, which contained the treasure of one hundred and three silver vases now in the Louvre. The villa of P. Fannius Synistor, not far off, was excavated in 1900, it had fine wall paintings, which were exported, and sold by auction in Paris (some now in the Louvre,

while others are in New York) (See F. Barnabei, *La Villa pompeiana di P. Fannius Synistor*, Rome, 1901.) Another, closer to Pompeii, in the so-called Villa Iken, contains remarkable life size frescoes representing scenes of initiation into the mysteries of Dionysus or of Orpheus.

The road leading towards Herculaneum is bordered on both sides for a considerable extent by tombs, in many instances monuments of considerable pretension, and of a highly ornamental character, which present in the highest degree the advantage common to all that remains of Pompeii, their perfect preservation.

There appears to have been in the same quarter a considerable suburb, outside the gate, extending on each side of the road towards Herculaneum, apparently much resembling those which are now found from thence to Naples. Other suburbs were situated at the harbour and at the saltworks (*salinae*).

No manuscripts have been discovered in Pompeii. Inscriptions have been found in considerable numbers, and give much information concerning the municipal arrangements of the town, as well as the construction of various edifices and other public works. The most interesting of these are such as are written in the Oscan dialect, which appears to have continued in official use down to the time when the Roman colony was introduced by Sulla. From that time the Latin language was the only one officially employed. Still more curious are the numerous writings painted upon the walls, which have generally a semi-public character, such as recommendations of candidates for municipal offices, advertisements, etc., and the scratched inscriptions (*graffiti*), which are generally the mere expression of individual impulse and feeling, frequently amatory, and not uncommonly conveyed in rude and imperfect verses. In one house also a whole box was found filled with written tablets—diptychs and triptychs—containing the record of the accounts of a banker named L. Caecilius Iucundus.

Beasley, London 1926), M. Della Corte, *Cats and abutants at Pompeii* (Pompeii, 1926) (E. H. B., T. A.)

POMPEIUS, GNAEUS, surnamed STRABO (squat-eyed), Roman statesman, father of the triumvir. He was successively quaestor in Sardinia (103 B.C.), praetor (94), proprietor in Sicily (93) and consul (89). He fought with success in the Social War, and was awarded a triumph for his services. Probably towards the end of the same year he brought forward the law (*lex Pompeia de Galia transpadana*), which conferred upon the inhabitants of that region the privileges granted to the Latin colonies. During the civil war between Marius and Sulla he seems to have shown no desire to attach himself definitely to either side. He set out for Rome, the engagement which he fought before the Colline gate, although hotly contested, was indecisive. Soon afterwards he was killed by lightning (87).

See Plutarch, *Pompey*, 1, Appian, *Bell. civ.* i 50, 52, 66-68, 80, Vell. Pat. ii 21, Livy, *Epit.* 74-79, Florus iii 18.

POMPEIUS, GNAEUS, surnamed MAGNUS (c. 75-45 B.C.), the elder son of the triumvir. In 48 B.C. during the civil war he commanded his father's fleet in the Adriatic. After the battle of Pharsalus he set out for Africa with the remainder of the Pompeian party, but, meeting with little success, crossed over to Spain. Having been joined by his brother Sextus, he collected a considerable army, the numbers of which were increased by the Pompeians who fled from Africa after the battle of Thapsus (46). Caesar, who regarded him as a formidable opponent, set out against him in person. A battle took place at Munda on March 17, 45, in which the brothers were defeated. Gnaeus managed to escape, but was soon (April 12) captured and put to death.

See Pseudo-Opian, *Bellum hispaniense*, 1-39; Lucan, *Pharsalia*, ix. 150; Dio Cassius, *id.* 48-49.

POMPEIUS, SEXTUS, surnamed **MAGNUS** (75-35 B.C.), the younger son of the triumvir. After his father's death he continued the struggle against the new rulers of the Roman empire. From Cyprus, where he had taken refuge, he made his way to Africa, and after the defeat of the Pompeians at Thapsus (46) crossed over to Spain. After Caesar's victory at Munda (45), he abandoned Corduba (Cordova), though for a time he held his ground in the south, and defeated Asinius Pollio, the governor of the province. In 43 he was proscribed by the triumvirate and put himself at the head of a fleet manned chiefly by slaves or proscribed persons, with which he made himself master of Sicily, and from thence ravaged the coasts of Italy. Rome was threatened with a famine, as the corn supplies from Egypt and Africa were cut off by his ships, and it was thought prudent to negotiate a peace with him at Misenum (39), which was to leave him in possession of Sicily, Sardinia and Achaia, provided he would allow Italy to be freely supplied with corn. But the arrangement could not be carried into effect, as Sextus renewed the war and gained some considerable successes at sea. However, in 36 his fleet was defeated and destroyed by Agrippa at Naulochus off the north coast of Sicily. After his defeat he fled to Mytilene, and from there to Asia Minor. In the attempt to make his way to Armenia he was taken prisoner by Antony's troops, and put to death at Miletus. See *Deo Cassius*, xlv, xlvii, Appian, *Bell. civ.* iv. 54-117, v. 2-143; *Veil. Pat.* ii. 72-87; Plutarch, *Antony*, *Lucy*, *Epi.* 123, 128, 129, 131; Cicero, *Philippica*, xii, and many references in *Letters to Atticus*.

POMPEY, the common English form of Pompeius, the name of a Roman plebeian family.

POMPEIUS, GNAEUS (106-48 B.C.), the triumvir, the first of his family to assume the surname **MAGNUS**, was born on Sept. 30, in the same year as Cicero. When only 17 he fought together with his father in the Social War. He took the side of Sulla against Marius and Cinna, but for a time, in consequence of the success of the Marians, he kept in the background. On the return of Sulla from the Mithridatic War Pompey joined him with an army of three legions, which he had raised in Picenum. Thus early in life he connected himself with the cause of the aristocracy, and a decisive victory which he won in 83 over the Marian armies gained for him from Sulla the title of *imperator*. He followed up his successes in Italy by defeating the Marians in Sicily and Africa, and on his return to Rome in 81, though he was still merely an *eques* and not legally qualified to celebrate a triumph, he was allowed by general consent to enjoy this distinction, while Sulla greeted him with the surname of *magnus*, a title he always retained and handed down to his sons. Latterly, his relations with Sulla were somewhat strained, after Sulla's death he resisted the attempt of the consul M. Aemilius Lepidus to repeal the constitution. In conjunction with A. Lutatius Catulus, the other consul, he defeated Lepidus when he tried to march upon Rome, and drove him out of Italy (77). He retained his army, and jockeyed the senate into sending him to Spain *pro consul* (though he had as yet held no magistracy) to deal with Sertorius. Pompey was fighting in Spain from 76 to 71. After Sertorius had fallen a victim to assassination, Pompey easily defeated his successor Perperna and put an end to the war. On his way back he met and cut up a body of slaves, part of Spartacus' defeated forces, in flight northwards. He demanded a triumph, and permission to stand for the consulate.

The Consul.—The senate was inclined to grudge it, so he entered into a coalition with Crassus, and as both had armies at the gates, there was no more to be said. Pompey and Crassus were consuls together in 70, and that year saw the work of Sulla undone, the tribunate and censorship were restored, and the administration of justice was shared between the Senate, the equites, and the *tribuni aerarii*.

Pompey rose still higher in popularity, and on the motion of the tribune Aulus Gabinius in 67 he was entrusted with an extraordinary command over the greater part of the empire, specially for the extermination of piracy in the Mediterranean, by which the corn supplies of Rome were seriously endangered, while the high prices of provisions caused great distress. He was completely successful; the price of corn fell immediately on his ap-

pointment, and in 40 days the Mediterranean was cleared of the pirates. Next year, on the proposal of the tribune Manilius, his powers were still further extended, the care of all the provinces in the East being put under his control for three years together with the conduct of the war against Mithridates VI., who had recovered from the defeats he had sustained from Lucullus and regained his dominions. Both Caesar and Cicero supported the tribune's proposal, which was easily carried in spite of some opposition in the senate. Pompey was entirely successful. Mithridates was beaten and driven into the Crimea, and there was a general settlement of affairs in the East. Syria and Palestine were annexed in 64 and 63. Tigranes of Armenia submitted and was confirmed as a vassal king, and an agreement was reached with Phraates of Syria whereby the Euphrates marked the boundary between them.

Pompey, now in his 45th year, returned to Italy in 61 to celebrate the most magnificent triumph which Rome had ever witnessed, as the conqueror of Spain, Africa and Asia.

Politics.—This triumph marked the turning-point in his career. As a soldier everything had gone well with him, as a politician he was a failure. He found a great change in public opinion, and the people indifferent to his achievements abroad. The senate had a unique chance to secure his support, but refused to ratify the arrangements he made in Asia or to provide money and lands for distribution amongst his veterans. In these circumstances he drew closer to Caesar on his return from Spain, and became reconciled to Crassus. The result was the first triumvirate. He was married to Caesar's daughter Julia, and as yet the relations between the two had been friendly. Pompey was now in fact ruler of the greater part of the empire, while Caesar had only the two provinces of Gaul. But being no political tactician, Pompey made no use of this advantage, and all this time the balance of power was steadily turning in Caesar's direction. The senate and the aristocracy disliked and distrusted Pompey, but they felt that, should things come to the worst, they might still find in him a champion of their cause. Hence the joint rule of Pompey and Caesar was not unwillingly accepted, and anything like a rupture between the two was greatly dreaded as the sure beginning of anarchy throughout the Roman world. In 55 Pompey was consul again, in accordance with the arrangement with Caesar when the triumvirate was renewed at Luca in 56. As proconsul he should have left for his province, but he remained in charge of the corn-supply, virtually master of Rome, and governed Spain by his *legati*. With the death of Pompey's wife Julia (54) and of Crassus (53) the relations between him and Caesar became strained, and soon afterwards he drew closer to the conservative party and married into the house of Scipio. In 52, in the utter disorder that followed the death of Clodius, he was elected sole consul, carried through the trial of Milo, and started a programme of administrative and provincial legislation threatening Caesar's position.

Civil War.—The crisis arrived with the approaching end of Caesar's command at the end of 50. Pompey nearly compromised by accepting the Parthian command and leaving Rome, but Marcellus forced his hand, and civil war began. Pompey, wisely or unwisely, abandoned Italy. His cause, with that of the senate and aristocracy, was finally ruined by his defeat by Julius Caesar in 48 in the neighbourhood of Pharsalus. That same year he fled with the hope of finding a safe refuge in Egypt, but was treacherously murdered by one of his old centurions as he was landing. He was five times married, and three of his children survived him—Gnaeus, Sextus, and a daughter Pompeia.

POMPONAZZI, PIETRO (PETRUS POMPONATIUS) (1462-1525), Italian philosopher, was born at Mantua on Sept. 16, 1462, and died at Bologna on May 18, 1525. He took his M.D.

at Padua in 1487 and was elected extraordinary professor of philosophy. From about 1495 to 1509 he occupied the chair of natural philosophy and when the schools of Padua closed, he took a professorship at Ferrara where he lectured on the *De anima*. From 1512 to his death he was at Bologna where he produced all his important works. In 1516 appeared his *De immortalitate animae*, which gave rise to a storm of controversy between the orthodox Thomists, the Averroists headed by Agostino Nifo, and the so-called Alexandrist School. The treatise was burned at Venice, and Pomponazzi himself ran serious risk of death. Two pamphlets followed, the *Apologia* and the *Defensorium*, wherein he explained his paradoxical position as Catholic and philosophic materialist. His last two treatises, the *De incantationibus* and the *De fato*, were posthumously published in an edition of his works printed at Basel.

See A. H. Douglas, *Philosophy and Psychology of Pietro Pomponazzi* (1910); J. A. Symonds, *The Renaissance in Italy*, L. Ferri, *La Psicologia di P. Pomponazzi* (1877); Überweg, *Grundriss der Gesch. der Philosophie* p. 1-3.

POMPOSA, an abbey of Emilia, Italy, in the province of Ferrara, 2 m from Codigoro, which is 30 m E of Ferrara in the delta of the Po. The fine church, a work of the 6th century, rebuilt in the 11th, with interesting sculptures and terra cotta decorations on the façade and a splendid Romanesque campanile 163 ft high (1063) contains a good mosaic pavement (1036) and interesting frescoes of the 14th century—a "Last Judgment" of the school of Giotto and others, and there are also paintings in the refectory. It was abandoned in 1650 on account of malaria.

See G. Agnelli, *Ferrara e Pomposa* (Bergamo, 1901), and F. R. Horns in *Journal of the Royal Institute of British Architects* xxxv. (1927) 355-599.

POMPTINE MARSHES, a low tract of land in the province of Rome, Italy, varying in breadth between the Volcanic mountains and the sea from 10 to 16 m., and extending north-west to south-east from Velletri to Terracina (40 miles). In ancient days this tract was fertile and contained prosperous cities (Suessa Pometia, Ulubrae—perhaps the mod. Costume—etc.), but it had already become unhealthy at the end of the Republican period. Attempts to drain the marshes were made by Appian Claudius in 312 B.C., when he constructed the Via Appia through them and at various times during the Roman period. A canal ran through them parallel to the road and was used in preference to the road during the Augustan period. Trajan repaired the road, and Theodoric did the same some 400 years later. But in the middle ages it had fallen into disrepair. Popes Boniface VIII, Martin V, Sixtus V, and Pius VI all attempted to solve the problem, the last-named reconstructing the road admirably. By a law passed in 1910 the special provisions for the obligatory improvement of the Roman Campagna had been extended to the Pomptine territory.

See T. Berti, *Paludi pontine* (Rome, 1884); R. de la Blanchère, *Un Chapitre d'histoire pontine* (Paris, 1889).

PONCA CITY, a city of Kay county, Okla., U.S., on the Arkansas river, at an altitude of 1,000 ft., 90 mi. N by E of Oklahoma City. It is on federal highways 60 and 77, has a municipal airport, and is served by the Rock Island and the Santa Fe railways.

The population in 1950 was 20,180. It is the second largest city in the historic Cherokee Strip; the trading point for six Indian tribes; and the centre of a large oil-producing district. The two large refineries located there, the Continental Oil company and the Cities Service Oil company, have a combined capacity of 80,000 bbl per day. Other industries in the city process agricultural products (wheat, dairy products and poultry); manufacture clothing, oil field drilling bits, farm equipment, and service diesel engines. The city is the home of the famous "Pioneer Woman" statue and Pioneer Woman State park, presented to the people of Oklahoma by Gov. E. W. Marland.

The first white settlement in what is now Oklahoma was Camp Ferdinand, a few miles northeast of Ponca City on the Arkansas river, established by French traders in the middle of the 18th century. Early in the 1880s, before Oklahoma was opened to

white settlement, the town of Rock Falls was established 25 mi NW of Ponca City, but the settlers were forced out of the territory by United States soldiers. Ponca City itself was established on Sept. 16, 1893, at the time of the opening of the Cherokee Strip. It took its name from the Ponca Indians, who were moved to Oklahoma by the government in 1879 and whose reservation lies 6 mi S of Ponca City. In 1950 the assessed valuation of the city was \$10,000,000 and of the school district \$28,000,000. The city's net bonded indebtedness was \$527,000 and the value of municipally owned property was \$3,441,000. The school district had a net bonded indebtedness of \$401,000, and the value of school property was \$2,000,000. There are no city taxes, all costs of operating the city government being met by the profit from the municipally owned water and light plants.

PONCE, the largest and most important city on the southern coast of Puerto Rico and the second city in size and importance on the island. The population in 1950 was 99,190. The population of the municipal district in 1950 was 126,451. Historians state that the city of Ponce was founded in 1762 and was made independent from the old town of San Blas de Illescas (modern Coamo) in 1778. After that its growth increased and its importance was greatly magnified. Ponce was one of the first places at which U.S. forces landed in Puerto Rico during the Spanish-American War. They took possession of the city, after having entered into an agreement with the Spanish forces who withdrew into the interior of the island.

Ponce has an agreeable climate, the temperature being moderated by the constant breezes prevailing during the greater part of the year. Industrially and commercially it is one of the foremost cities of the island.

Ponce is the principal shipping port on the Caribbean sea, and has a large commerce with the southern islands and the northern countries of South America. Extensive improvements of the harbour were made under the direction of U.S. agencies.

Ponce is a well-managed city and its streets, plazas, parks and recreation grounds are well-kept and attractive. Its public buildings and private residences are well-built.

The city is on the line of the American railroad, and is the terminus of important highways, north, east and west. There is regular air service from San Juan. There are several banks and some important commercial and industrial firms, producing cigars and cigarettes, bay rum, mineral waters, hats, shoes, clothing, lace, embroidery, cut diamonds, foundry and iron products, ice, brick, chocolate, soap and candy. In 1948 the University of Santa Maria, a Catholic private institution, was founded at Ponce with donations for construction and operation.

(H. M. T., J. L. Et.)

PONCE DE LEÓN, JUAN (c. 1460–1521), discoverer of Florida, was born in Servas, Spain, about 1460. He took part in the Moorish wars and then sailed for America with Columbus on his second voyage (1493). In 1509 he conquered Porto Rico and was appointed governor. As soon as the island was under control and pacified he set out with three ships to search for the land of "Bimini," wherein, as the Indian legend told him, there was a fountain with waters of marvellous curative power. On Mar. 27, 1513, he discovered the mainland which he named Florida because the day was Easter Sunday (*Pascua Florida*). He landed north of the present site of St. Augustine on April 2, and on April 8 took possession in the name of the Spanish king. He afterwards explored the coast southward to the cape and up the west shore of the peninsula to at least 27° 30', and perhaps to where the coast trended westward. He returned to Spain in 1514, and received an appointment from Ferdinand V. as governor of "The Island of Florida." In 1521 he set out to conquer and colonize his possession but the fierceness of the natives prevented his success. In a sharp engagement Ponce de León was mortally wounded and his force driven to the ships. He died in Cuba in June 1521.

See F. A. Ober, *Ponce de León* (1908); Justin Winsor, *Narrative and Critical History of America*, vol. II chap. IV (1886); "The Track of Ponce de León," *Amer. Geog. Soc. Bulletin*, xlv, pp. 721–735 (1913); *Boletín histórico de Puerto Rico*, Año I, pp. 118–161 (1914).

PONCELET, JEAN VICTOR (1788-1867), French mathematician and engineer, was born at Metz on July 1, 1788. From 1808 to 1810 he attended the *École polytechnique*, and afterwards, till 1812, the *École d'application* at Metz. He then became lieutenant of engineers, and took part in the Russian campaign, during which he was taken prisoner and was confined at Saratov on the Volga until 1814, when he returned to France. During his imprisonment he began his researches on projective geometry which led to his great treatise on that subject. This work, the *Traité des propriétés projectives des figures*, which was published in 1822 (2d ed., 2 vols 1865-66), is occupied with the investigation of the projective properties of figures (see GEOMETRY), and entitles Poncelet to rank as one of the greatest of those who took part in the development of the new geometry of which G. Monge was the founder. Poncelet developed the principle of Duality, and discovered the circular points at infinity, so causing the principle of continuity to be recognized. From 1815 to 1825 he was occupied with military engineering at Metz, and from 1825 to 1835 he was professor of mechanics at the *École d'application* there. In 1834 he became a member of the *Académie*, from 1838 to 1848 he was professor to the faculty of sciences at Paris, and from 1848 to 1850 commandant of the *École polytechnique*. He died at Paris on Dec. 22, 1867.

Poncelet's works include *Cours de mécanique, appliquée aux machines* (1826), and *Mémoire sur les roues hydrauliques à aubes courbes* (1826). See J. Bertrand, *Éloge historique de Poncelet* (1875).

PONCHIELLI, AMILCARE (1834-1886), Italian musical composer, was born near Cremona on Sept. 1, 1834, and studied at the Milan Conservatoire. He attained his fame with *La Gioconda* (1876), written to a libretto founded by Arrigo Boito upon Victor Hugo's tragedy, *Angelo, Tyran de Padoue*. *La Gioconda* was followed by *Il Figliuol prodigo* (1880) and *Marion Delorme* (1885). In 1881 Ponchielli was made maestro di cappella of Piacenza cathedral. He died at Milan on Jan. 17, 1886.

POND, JOHN (c. 1767-1836), English astronomer-royal, was born about 1767 in London. After leaving Trinity college, Cambridge, he settled at Westbury near Bristol, and began to determine star-places with a fine altitude and azimuth circle of 2½ ft diameter by E. Troughton. His demonstration in 1806 (*Phil. Trans.* xvi. 420) of a change of form in the Greenwich mural quadrant led to the introduction of astronomical circles at the Royal Observatory, and to his own appointment as its head. He was elected a fellow of the Royal Society on Feb. 26, 1807, he married and went to live in London in the same year, and in 1811 succeeded Maskelyne as astronomer-royal.

Under Pond the instrumental equipment at Greenwich was completely changed, and the number of assistants increased from one to six. The superior accuracy of his determinations was attested by S. C. Chandler's discussion of them in 1894, in the course of his researches into the variation of latitude (*Astron. Jour.* Nos 313, 315). Pond received many academic honours. He published eight folio volumes of *Greenwich Observations*, translated Laplace's *Système du monde* (in 2 vols 8vo, 1809), and contributed thirty-one papers to scientific collections. His catalogue of 1,112 stars (1833) was of great value. He retired in 1835 and died at Blackheath on Sept. 7, 1836, and was buried beside Halley in the churchyard at Lee.

Airy's *Autobiography*, p. 127; *Observatory*, xii. 204, xiii. 357; *Annual Biography and Obituary* (1837), R. Grant *Hist. of Phys. Astron.* p. 491, *Royal Society's Cat. Scient. Papers*, Maunders, *The Royal Observatory Greenwich*.

POND, a small pool of standing water, the name is usually applied to one for which the bed has been artificially constructed. The term is a variant of "pond" (q.v.), an enclosure.

PONDICHERY, the capital of the French possessions in India, situated on the Coromandel or eastern coast, 122 mi by rail S of Madras. The territory, which is entirely surrounded by the British district of South Arcot, has an area of 113 sq mi, with a population (1941) of 204,653. It is ruled by a governor, with a privy council, and a general council, and is represented

in the French senate and chamber. The chief crops are dry grains, rice, earth-nuts and a little indigo. The territory is traversed by a branch of the South Indian railway from Villupuram. The town (pop. [1941] 53,101) is well laid out with fine public buildings, and lit by electricity, the water-supply is derived from artesian wells. There is a college, and a fine Court of Appeal building was erected.

Pondicherry was founded in 1683 by François Martin, on the site of a village given him by the governor of Gingee. In 1693 the Dutch took Pondicherry, but restored it, with the fortifications greatly improved, in 1697, at the peace of Ryswick. In 1748 Admiral Boscawen laid siege to it without success, but in 1761 it was taken by Colonel Coote from Lally. In 1763 it was restored to the French. In 1778 it was again taken by Sir Hector Munro, and its fortifications destroyed. In 1783 it was retransferred to the French, and in 1793 recaptured by the English. The treaty of Amiens in 1802 restored it to the French, but it was retaken in 1803. In 1816 it was restored to the French.

PONDO, a Kafir people who have given their name to Pondoland, the country comprising much of the seaboard of Kaifarra, Cape province, immediately to the south-west of Natal.

PONDWEED, a popular name for *Potamogeton natans*, a cosmopolitan aquatic plant found in ponds, lakes and ditches, with broad, more or less oblong-ovate, olive-green, floating leaves. The name is also applied to other species of *Potamogeton*, one of the characteristic genera of lakes, ponds and streams all over the world, but more abundant in temperate regions, embracing about 90 species. It is the principal genus of the family Potamogetonaceae, and contains plants with slender branched stems, and submerged and translucent, or floating and opaque, alternate or

opposite leaves, often with membranous united stipules. The small flowers are borne above the water in axillary or terminal spikes; they have four stamens, which bear at the back four small herbaceous petal-like structures, and four free carpels, which ripen to form four small green fleshy fruits, each containing one seed within a hard inner coat, the seed contains a large hooked embryo. An allied genus *Zannichellia*, occurring in fresh and brackish ditches and pools in Great Britain and nearly throughout North America, and also widely elsewhere in temperate and tropical regions, is known as horned pondweed, from the curved fruit.

See P. Ascherson and P. Graebner, "Potamogetonaceae," *Pflanzenreich* 31 (iv, 1), 1-184, fig. 1-36 (1907).

PONGEE, a plain-weave fabric made of *tussah* or wild silk, originated with the Chinese in ancient times. Its sphere of usefulness has been broadened due chiefly to the increase in standard width from 18 to 36 or more inches, and the variety of colours extended. The Japanese buy from the Chinese the wild silk and work it up in their own plants. *Shantung*, a variety of pongee, derives its name from the province which is the centre of the wild silk industry. It differs from true pongee in that the former must be a plain weave, while Shantung may include many types, even adding coloured threads for decoration. Because of the ease with which they can be laundered and their durability pongees are among the most practical of silks.

PONIARD, a dagger, particularly one of small size, used for stabbing at close quarters. The French word *poignard*, from which the English is a 16th century adaptation, is formed from *poing*, fist, in which the weapon is grasped. (See DAGGER.)

PONIATOWSKI, the name of a Polish princely family of Italian origin, tracing descent from Giuseppe Torelli, who married about 1650 an heiress of the Lithuanian family of Poniatov, whose name he assumed.

STANISLAUS PONIATOWSKI (1677-1762), only belonged to the

FROM STRASSBURGER, "LEHRBUCH DER BOTANIK FÜR HOCHSCHULEN" (BUSTAV FISCHER).
PONDWEED (POTAMOGETON NATANS), SHOWING FLOWERING STEM AND LEAVES

family by adoption, being the reputed son of Prince Sapieha and a Jewess. He was born at Derezyn in Lithuania, and was adopted by Sapieha's intendant, Poniatowski. Attaching himself to the party of Stanislaus Leszczyński, he became major-general in the army of Charles XII of Sweden, who also employed him as diplomatic intermediary to the Sultan. He next became governor of the duchy of Zweibrücken, Bavaria. After the death of Charles XII in 1718 he visited Sweden, and was subsequently reconciled with Leszczyński's rival on the throne of Poland, Augustus II, who made him grand treasurer of Lithuania in 1724. On the death of Augustus II he tried to secure the reinstatement of Leszczyński, but presently gave his allegiance to Augustus III, by whom he was made governor of Cracow. He died at Ryki on Aug. 3, 1762.

His second son Stanislaus Augustus became king of Poland (See STANISLAUS II). Of the other sons, Casimir (1721-1780) was his brother's chancellor, Andrew (1735-1773) became feldzeugmeister in the Austrian service, and Michael (1736-1794) became archbishop of Gnesen and primate of Poland. Joseph Anthony (q.v.), son of Andrew, became one of Napoleon's marshals.

STANISLAUS PONIATOWSKI (1757-1833), son of Casimir, was grand treasurer of Lithuania, starost of Podolia and lieutenant-general of the royal army. In 1793 he settled in Vienna, and subsequently in Rome, where he made a magnificent collection of antique gems, subsequently sold. He died in Florence, Feb. 13, 1833, and the Polish and Austrian honours became extinct.

His natural, but unrecognized, son, JOSEPH MICHAEL XAVIER FRANCIS JOHN PONIATOWSKI (1816-1873), was born at Rome and in 1847 was naturalized as a Tuscan subject. He received the title of prince in Tuscany (1847) and in Austria (1850). He represented the court of Tuscany in Paris from 1848, and he was made a senator by Napoleon III, whom he followed to England in 1871. He also wrote numerous operas. He died on July 3, 1873. His son, Prince Stanislaus Augustus, married and settled in Paris. He was equerry to Napoleon III, and died in Jan. 1908.

PONIATOWSKI, JOSEPH ANTHONY (1763-1813), Polish prince and marshal of France, son of Andrew Poniatowski and the countess Theresa Kinsky, was born at Warsaw in 1763. He served with distinction in the imperial forces against the Turks in 1788, then becoming major-general and subsequently lieutenant-general in the Polish army under his uncle, King Stanislaus. In 1789 he commanded the Ukrainian division; and after the proclamation of the constitution of May 3, 1791, was made commander-in-chief. Aided by Kosciuszko, he conducted the operations against Russia with much skill, but when the king acceded to the confederation of Targowica (See POLAND: History), at the same time guaranteeing the adhesion of the army, Poniatowski, and most of the other generals threw up their commissions and emigrated. During the Kosciuszko rising he again fought gallantly for his country under his former subordinate, and after the fall of the republic lived in retirement. After the evacuation of the Polish provinces by Prussia, Poniatowski became commander of the National Guard, and on the creation of the grand duchy of Warsaw he was nominated war minister.

During the war of 1809, he operated successfully against the Austrians. In Napoleon's campaign against Russia in 1812 Poniatowski commanded the fifth army corps, and after the disastrous retreat of the grand army remained faithful and formed a new Polish army of 13,000 men, with which he joined the emperor at Lutzen. In 1813 he guarded the passes of the Bohemian mountains and defended the left bank of the Elbe. As a reward for his brilliant services at Leipzig he was made a marshal of France and entrusted with the duty of covering the retreat of the army, in the course of which he perished, fighting heroically against overwhelming odds. His relics were conveyed to Poland and buried in Cracow Cathedral, where he lies by the side of Tadeusz Kosciuszko and Jan Sobieski. Poniatowski's *Mes souvenirs sur la campagne de 1792* (Lemberg, 1863) is of historical value.

See *Correspondence of Poniatowski* (ed. E. Raczyński, Posen, 1843); Bronisław Dembinski, *Stanislaus Augustus and Prince Joseph Poniatowski in the light of their Correspondence* (Fr.; Lemberg, 1904); Szymon Askenazy, *Prince Joseph Poniatowski* (Pol.; Warsaw, 1905).

PONS, JEAN LOUIS (1761-1831), French astronomer, was born at Peyres (Hautes Alpes) on Dec. 24, 1761. He entered the Marseilles observatory in 1789, and in 1819 became the director of the new observatory at Marlia near Lucca, which he left in 1825 for the observatory of the museum at Florence. Here he died on Oct. 14, 1831. He spent his time searching for comets, of which he discovered a record number; some bear his name, e.g., Pons-Winnecke's comet.

See M. R. A. Henrion, *Annuaire biographique*, i. 288 (1834); *Mémoires Roy. Astron. Soc.* v. 410, R. Wolf, *Geschichte der Astronomie*, p. 709; J. C. Poggendorff, *Biog. lit. Handwörterbuch*.

PONSARD, FRANÇOIS (1814-1867), French dramatist, was born at Vienne, Isère, on June 1, 1814, and studied law. His translation of *Manfred* was published in 1837. His play *Lucrèce* was represented at the Théâtre Français on April 1, 1843. This date marks a reaction against the romantic style of Dumas and Hugo. He received, in 1845, the Academy's prize for a tragedy "to oppose a dike to the waves of romanticism." Ponsard combined the liberty of the romantics with the sober style of earlier French drama. The success of his plays was aided by the impersonation of many of the principal rôles in them by Rachel. He followed up *Lucrèce* with *Agnès de Méranie* (1846), *Charlotte Corday* (1850), and others. *L'Homme et l'argent*, one of his most successful plays, was acted in 1853, and he became an academicien in 1855. In 1866 he obtained great success with *Le Lion Amoureux*, another play dealing with the revolutionary epoch. His *Gaîté*, which excited great opposition in the clerical camp, was produced in 1867. He died in Paris on July 7, 1867.

His *Oeuvres complètes* were published in Paris (3 vols., 1865-76). See C. Latreille, *Le Fin du théâtre romantique et François Ponsard d'après des documents inédits* (1899).

PONSONBY OF SHULBREDE, ARTHUR AUGUSTUS WILLIAM HARRY PONSONBY, 1ST BARON (1871-1946), British author and politician, was born on Feb. 16, 1871, and educated at Eton and at Balliol college, Oxford. In 1894 he entered the diplomatic service, and after holding posts in Constantinople and Copenhagen, returned in 1902 to join the staff of the foreign office. In 1906 he became principal private secretary to Sir Henry Campbell-Bannerman, and in 1908 was elected Liberal M.P. for Surling. He represented this constituency until 1918, and in 1922 was elected Labour member for the Brightside division of Sheffield, and held minor posts in the Labour governments of 1924 and 1929-31. He was raised to the peerage in 1930, and was leader of the opposition in the house of lords from 1931 to 1935. He died at Hindhead, Surrey, March 24, 1946.

His works include *The Decline of Aristocracy* (1912); *Democracy and Diplomacy* (1915); *Wars and Treaties* (1815-1914) (1917); *Now is the Time* (1925); *Life Here and Now* (1936).

PONSONBY, English family. **PONSONBY, JOHN** (1713-1789), Irish politician, was born on March 29, 1713. In 1739 he entered the Irish parliament, where he became first commissioner of the revenue (1744), a privy councillor (1746), and in 1756 Speaker. Belonging to one of the great families which at this time monopolized the government of Ireland, Ponsonby was one of the principal "undertakers," men who controlled the whole of the king's business in Ireland, and he retained the chief authority until the marquess Townshend became lord-lieutenant in 1767. A struggle for supremacy between the Ponsonby faction and the party dependent on Townshend followed, which caused Ponsonby to resign the speakership in 1771. He died on Dec. 13, 1789. His wife was Elizabeth, daughter of William Cavendish, 3rd duke of Devonshire, a connection of advantage to the Ponsonbys.

Ponsonby's third son, **GEORGE PONSONBY** (1755-1817), lord chancellor of Ireland, was born on March 5, 1755, and educated at Trinity College, Cambridge. A barrister, he became a member of the Irish parliament in 1776 and was chancellor of the Irish exchequer in 1782, afterwards taking part in the debates on the question of Roman Catholic relief, and leading the opposition to the union of the parliaments. Ponsonby represented Wicklow and then Tavistock in the united parliament, in 1806 he was lord chancellor of Ireland, and from 1808 to 1817 he was the official leader of the opposition in the House of Commons.

He left an only daughter when he died in London on July 8, 1817.

George Ponsonby's elder brother, WILLIAM BRABAZON PONSONBY, 1st Baron Ponsonby (1744–1806), was also a leading Whig politician, being a member of the Irish and, after 1800, of the British parliament. In 1806, shortly before his death, he was created Baron Ponsonby of Imokilly. On the death of his grandson, WILLIAM BRABAZON PONSONBY (1807–1866), the barony became extinct.

PONTA DELGADA, the capital of an administrative district, comprising the islands of St. Michael's and St. Mary in the Portuguese archipelago of the Azores. Pop. (1940) 21,048. Ponta Delgada is built on the south coast of St. Michael's, in 37° 40' N and 25° 36' W. Its mild climate and the fine scenery of its mountain background render it very attractive to visitors, it is the commercial centre and the most populous city of the archipelago.

Great improvements in the harbour were effected after 1860 by the construction of a breakwater 2,800 ft. long.

PONT-À-MOUSSON, a town of northern France in the department of Meurthe-et-Moselle, 17 mi. NNW of Nancy by rail. Pop. (1946) 10,278. Dating from the 9th or 10th century, Pont-à-Mousson constituted a lordship, which was made a marquessate in 1354. It was from 1572 to 1763 the seat of a well-known university. The Moselle, which is canalized, divides the town into two quarters, united by a 16th-century bridge. The church of St. Martin dates from the 13th, 14th and 15th centuries. The lower ecclesiastical seminary occupies the building of an old Premonstratensian convent.

PONTANUS, JOVIANUS (1426–1503), Italian humanist and poet, was born in 1426 at Cerreto, in the duchy of Spoleto, and educated, after the death of his father in a civil disturbance, at Perugia. At the age of 22 he went to Naples, where he remained for the rest of his life. He became a friend of the famous scholar Antonio Beccadelli, and was introduced by him to Alfonso the Magnanimous, who made him tutor to his sons. Thereafter he was political adviser, military secretary and chancellor to the Aragonese dynasty. He illustrates very clearly the importance of men of letters in Italy. He arrived in Naples a penniless scholar, and became almost immediately one of the most important men in the kingdom. He founded an academy for the meetings of scholars in Naples, which lasted long after his death. In 1461 he married Adriana Sassone, who bore him one son and three daughters and died in 1491. Soon after this he married a girl from Ferrara, known to us only as Stella. He was passionately fond of wife and children, and much of his verse, especially *Eridanus*, written after his second marriage, tells of his love for them.

Pontanus outlived Stella also, and died in 1503 at Naples, where a group of life-size terra-cotta figures is still to be seen on his tomb at Monte Oliveto church. Pontanus had a good Latin style and the faculty, rare among his contemporaries, of expressing the facts of modern life, the actualities of personal emotion, in language sufficiently classical yet always characteristic of the man. His ambitious *Urania* embodies the astronomy of the day. His most original compositions in verse, however, are elegiac and hendecasyllabic pieces on personal topics—the *De conjugibus amore*, *Eridanus*, *Tumuli*, *Noemae*, *Baiae*, etc.—in which erotic freedom is condoned by a passionate sincerity. Pontanus' prose and poems were printed by the Aldi at Venice. For his life see Arditio, *Giovanni Pontano e i suoi tempi* (Naples, 1871), for his place in the history of literature, J. A. Symonds, *Renaissance in Italy* (1875, etc.).

PONTARLIER, a frontier town of eastern France, 36 mi. SE. of Besançon. Pop. (1946), 12,722. It is situated 2,750 ft. above sea level on the Doubs, about 4 mi. from the Swiss frontier, and forms an important strategic point at the mouth of the defile of La Cluse, one of the principal passes across the Jura.

Pontarlier is the junction of railway lines to Neuchâtel, Lausanne, Lons-le-Saunier, Dôle and Besançon. At Pontarlier the French army of the east made its last stand against the Prussians in 1871 before crossing the Swiss frontier.

The distillation of herbs, largely grown for kirsch and other

liqueurs, is the chief industry.

PONT AUDEMER, a town of northwestern France, in the department of Eure, 39 mi. NW of Evreux, on the railway to Honfleur. Pop. (1946) 6,119. The town owes its name to Audomar, a Frankish lord, who in the 7th or 8th century bridged the Risle there. The church of St. Owen, which has fine stained glass of the 16th century, combines the late Gothic and Renaissance styles, its choir is Romanesque. Manufacturing includes malleable metal founding, glue, leather goods and paper and cotton spinning. There is trade in flax, wool, grain, cattle, cider, paper, iron, wood and coal. The port has a length of more than one-half mile on the Risle, which is navigable for small vessels from this point to the Seine (10 mi.).

PONTECORVO, a city of Lazio, It., in the province of Frosinone, on the Garigliano, about 48 mi. from Caserta and 3 mi. from Aquino on the railway from Rome to Naples. Pop. (1936) 14,437 (town and the commune). The principality of Pontecorvo (about 40 sq. mi. in extent), once an independent state, belonged alternately to the Tomacelli and the abbots of Monte Cassino. Napoleon bestowed it on Bernadotte in 1806, and in 1810 it was incorporated with the French empire.

PONTÉCOULANT, LOUIS GUSTAVE LE DOULCET, COMTE DE (1764–1853), French politician, was born at Caen on Nov. 17, 1764. He entered the army in 1778. A moderate supporter of the revolution, he was returned to the convention for the department of Calvados in 1792 and became commissary with the army of the north. He attached himself to the party of the Gironde, and in Aug. 1793 was outlawed. He refused to defend his compatriot Charlotte Corday, who wrote him a letter of reproach on her way to the scaffold. He returned to the convention on March 8, 1795, and became its president in July, he was for several months a member of the council of public safety. He was elected to the council of 500, but was suspected of royalist leanings, and spent some time in retirement before the consulate. Becoming senator in 1805, and count of the empire in 1808, he organized the national guard in Franche-Comté in 1811 and the defense of the northeastern frontier in 1813. He sat in the upper house under the restoration. He died in Paris on April 3, 1853.

See his *Souvenirs historiques et parlementaires 1764–1848*, 4 vol. (1861–65).

PONTEFRACI (pronounced and sometimes written "Pomfret"), market town, municipal borough, in the West Riding of Yorkshire, Eng., 21 mi. SW from York, served by the London Midland Region railway. Pop. (1951) 23,173. Area, 7.6 sq. mi. It is well situated on an eminence near the junction of the Aire and the Calder. The most important remains are those of the famous castle, situated on a rocky height and containing eight round towers. The remains are principally of Norman date, and an unusual feature is the existence of various subterranean chambers in the rock. Below the castle is All Saints church, which suffered severely during the siege of the castle but still retains some work of the 12th century. In 1837 the tower and transepts were fitted for divine service. In Southgate is an ancient hermitage and oratory, cut from the solid rock, which dates from 1396. At Monk-hill there are the remains of a Tudor building called the Old Hall. A grammar school of ancient foundation, renewed by Elizabeth and George III, occupies modern buildings. The town hall (18th century) occupies the site of one erected in 1656, which succeeded the old moot hall dating from Saxon times. Among other buildings are the courthouse, the market hall, the assembly rooms and large barracks. The foundation of the principal almshouse, that of St. Nicholas, dates from before the Conquest. Trinity hospital was founded by Sir Robert Knolles (d. 1407). At Ackworth is a Society of Friends' school (1778), in the foundation of which John Fothergill (1712–80) was a prime mover. There are extensive gardens and nurseries in the neighbourhood of Pontefract, and liquorice is grown for the manufacture of the celebrated Pomfret cakes. The town possesses iron foundries, sack and maling manufactories, tanneries, breweries, corn mills and brick and terra-cotta works.

The remains of a Roman camp have been discovered near Pon-

tract. At the time of the Domesday Survey Tateshall (now Tanshelf, a suburb of the town) was the chief manor while Kirkby, afterwards the borough of Pontefract, was one of its members. The change of status was probably owing to the founding by Gilbert de Lacy, of a castle at Kirkby. The town was known as Pontefract in 1140 when Archbishop Thurstan died there. The manor remained in the Lacy family until it passed by marriage to Thomas, duke of Lancaster, who was beheaded after the battle of Boroughbridge. His estates were restored to his brother Henry, earl of Lancaster, on the accession of Edward III, and the manor thereafter formed part of the duchy of Lancaster. The town took part in most of the rebellions in the north of England, and in 1399 Richard II was imprisoned and secretly murdered in the castle. During the Wars of the Roses the town was loyal to Henry VI, and several of the Yorkist leaders were executed here after the battle of Wakefield. It was taken by Robert Aske, leader of the Pilgrimage of Grace, in 1536. In 1642 the castle was garrisoned for Charles I and sustained four sieges, the second in 1644, being successful, but two years later it was retaken by the royalists, who held it until after the execution of the king, when they surrendered to General Lambert and the castle was destroyed.

Roger de Lacy in 1194 granted a charter and in 1484 Richard III incorporated the town. The market rights are still held under his charter. The privilege of returning two members to parliament which had belonged to Pontefract at the end of the 13th century was revived in 1620-21. Between 1885 and 1918 it returned one member, when its representation was merged in that of the county, its name being given to the division.

PONTEVEDRA, a maritime province of northwestern Spain, before 1833 a part of Galicia. Pop (1950), 661,432, area, 1,695 sq mi, with a density of population, 390 2 inhabitants per square mile. The surface is mountainous. The coast line is deeply indented, navigation is rendered difficult by fogs in summer and storms in winter. Large agricultural fairs are held in the chief towns, and there is export of cattle, hams, salt meat and fish, eggs, breadstuffs, leather and wine. Vigo is the chief port and there are harbours at Bayona, Carril, Marín, Villagarcía and elsewhere among the deep estuaries of the coast. At Tuy the Spanish and Portuguese railways meet.

PONTEVEDRA, the capital of the Spanish province of Pontevedra, on the Tuy-Corunna railway, and on the river Lerez, which here enters the Ría de Pontevedra, an inlet of the Atlantic. Pop. (1950) 20,200 (mun. 51,933). The name of the town is derived from the ancient Roman bridge (*pons vetus*) of twelve arches, which spans the Lerez near its mouth. Pontevedra is mainly built of granite, and still partly enclosed by mediaeval fortifications. There is an active trade in grain, wine and fruit; cloth, hats, leather and pottery are manufactured.

PONTIAC (c. 1720-1769), famous chief of the Ottawa Indians and leader in the "Conspiracy of Pontiac" in 1763-64, was born about 1720, probably on the Maumee river, in what is now northwestern Ohio. His father was an Ottawa, and his mother an Ojibwa. By 1755 he had become a chief of the Ottawa and a leader of the loose confederacy of the Ottawa, Potawatomi and Ojibwa. As an ally of France, he possibly commanded the Ottawa in the defeat (1755) of Gen. Braddock. In 1760 he met Maj. Robert Rogers, then on his way to occupy Michilimackinac and other forts surrendered by the French, and agreed to let the English troops pass unmolested on condition that he should be treated with respect by the British. Like other Indians he soon realized the difference between French and English rule—that the Indians were no longer welcomed at the forts and that they would ultimately be deprived of their hunting grounds by encroaching English settlements. French hunters and traders encouraged Indian disaffection with vague promises of help from France, and in 1762 Pontiac enlisted the support of practically all the Indian tribes from Lake Superior to the lower Mississippi for a joint move to expel the British. He arranged for each tribe to attack the fort nearest to it in May 1763, and then to combine to wipe out the undefended settlements. Pontiac himself decided to capture Detroit, but his carefully laid plans for a surprise attack on May 9 were betrayed to the commanding officer, Maj. Gladwin,

and he was forced to lay siege to the fort. The siege continued for five months, marked by desultory attacks and sorties. Schooners sent through Lake Erie with supplies and provisions were captured by the Indians, but Pontiac could not prevent reinforcements from Fort Niagara under Capt. Dalzell from reaching Detroit. However, when the besieged made a night attack on the Indian encampment, Pontiac, apprised of their coming, inflicted heavy losses on them at Bloody Run, July 31. The Indians were unused to making long sieges and, after a few months, several of the associated tribes made peace. With his own Ottawa, Pontiac continued to camp around Detroit until Oct. 30 when, hearing that no aid from the French could be expected owing to the signing of the peace treaty with the English, he withdrew to the Maumee river.

Pontiac's larger plan was more successful. Of the 12 fortified posts attacked by the Indians, all but four were captured, most of the garrisons were massacred; several relief expeditions were nearly annihilated, and the frontiers were desolated and plundered. Col. Bouquet, however, succeeded in defeating the Indians at Bushy Run, when on his way to relieve Forts Pitt and Ligonier, and in 1764, he led a second expedition into Ohio from Pennsylvania, and forced the Indian tribes to sue for peace and release their prisoners. Pontiac still hoped to arouse other tribes to continue the fight, but after another year he saw that the English were the real masters of the situation and, on behalf of the tribes lately banded in his league, he concluded a treaty of peace and amity with Sir William Johnson at Oswego, N.Y., July 25, 1766. Pontiac, laden with gifts from the enemy, returned to his home on the Maumee. He met his death in 1769 at the hands of an Illinois Indian bribed by an English trader to murder him at Cahokia (nearly opposite St. Louis). His death occasioned a bitter war among the Indians, and the Illinois group was all but annihilated by his avengers. Pontiac was one of the most remarkable men of the Indian race in American history, possessing a commanding energy and force of mind combined with subtlety and craft, and a power of organization.

PONTIAC, a city of Illinois, U.S., on the Vermilion river, 92 mi. S.W. of Chicago, the county seat of Livingston county. It is on highways 66, 116 and 23, and is served by the Gulf, Mobile and Ohio, the Illinois Central and the Wabash railways. Pop. 8,990 in 1950, 1940 population 9,585 by the federal census. It is the trading and shipping point for a rich agricultural region. Creameries, hatcheries, shoe, heel and glove factories, hybrid seed companies, limestone quarries and printing are its chief industries. It is the seat of a state penitentiary. The city was founded in 1837 and incorporated in 1872.

PONTIAC, a city of Michigan, U.S., 26 mi. N.W. of Detroit, on federal highways 10 and 24 and state highway 59, the county seat of Oakland county. It is served by the Grand Trunk Western railroad and by intercity motor coach and truck lines. The population in 1950 was 73,681, in 1940, 66,626, by federal census. Pontiac is an important automobile manufacturing centre in the midst of a picturesque summer resort region. There are 11 state parks and 1 county park in the county, which contains more than 400 lakes. At Orchard lake (2 mi. S.E.) is Apple Island, formerly the home of the famous Chief Pontiac, and on its shores are ancient burial grounds of the Sac, Huron and Wyandot Indians. The city's industries include automobiles, motor trucks, motor coaches, automobile engines, bodies, parts and accessories, door forgings, tools and dies, paints and varnishes. The city has a land area of 19.8 sq mi. and had an assessed property valuation in 1950 of \$140,965,315.

There are more than 800 retail establishments. The city operates a municipal airport, 6 parks, 1 golf course, 26 schools with an enrolment of 14,837, and a public library. The Eastern State hospital for the insane is there. Pontiac was first settled in 1818, became the county seat in 1820 and was chartered as a city in 1861.

PONTIANUS, pope from 230 to 235. He was exiled to Sardina by the emperor Maximinus, and in consequence of this sen-

tence resigned (Sept. 28, 235). He was succeeded by Anteros.

PONTIFEX. The *collegium* of the *pontifices* was the most important priesthood of ancient Rome, being specially charged with the administration of the *jus divinum*, i.e., that part of the civil law which regulated the relations of the community with the deities recognized by the State officially, together with a general superintendence of the worship of gods and family. The name is clearly derived from *pōns* and *facere*, but whether this indicates any special connexion with the sacred bridge over the Tiber (*Pons Sublicus*) cannot now be determined. The college existed under the monarchy, when its members were probably three in number; they may be considered as legal advisers of the *rex* in all matters of religion. Under the republic they emerge into prominence under a *pontifex maximus*, who took over the king's duties as chief administrator of religious law, just as his chief sacrificial duties were taken by the *rex sacrorum*; his dwelling was the *regia*, "the house of the king." During the republican period the number of *pontifices* increased, probably by multiples of three, until after Sulla (82 B.C.) we find them 15, for the year 57 B.C. we have a complete list of them in Cicero (*Harusp. resp.* 6, 12). Included in the *collegium* were also the *rex sacrorum*, the *flamines*, three assistant *pontifices* (*minores*), and the vestal virgins, who were all chosen by the *pontifex maximus*. Vacancies in the body of *pontifices* were originally filled by co-optation; but from the second Punic war onwards the *pontifex maximus* was chosen by a peculiar form of popular election, and in the last age of the republic this held good for all the members. They all held office for life.

The immense authority of the college centred in the *pontifex maximus*, his functions being *ius consultum* or advising body. His functions were partly sacrificial or ritualistic, but these were the least important, the real power lay in the administration of the *jus divinum*, the chief departments of which may briefly be described as follows: (1) the regulation of all expiatory ceremonies needed as the result of pestilence, lightning, etc.; (2) the consecration of all temples and other sacred places and objects dedicated to the gods by the State through its magistrates; (3) the regulation of the calendar both astronomically and in detailed application to the public life of the State; (4) the administration of the law relating to burials and burying-places, and the worship of the Manes, or dead ancestors; (5) the superintendence of all marriages by *confarreatio*; i.e., originally of all legal patrician marriages; (6) the administration of the law of adoption and of testamentary succession. They had also the care of the State archives, of the lists of magistrates, and kept records of their own decisions (*commentarii*) and of the chief events (*annales*).

It is obvious that a priesthood with such functions and holding office for life, must have been a great power in the State, and for the first three centuries of the republic it is probable that the *pontifex maximus* was in fact its most powerful member. The office might be combined with a magistracy, and, though its powers were declaratory rather than executive, it may be described as quasi-magisterial. Under the later republic it was coveted chiefly for the great dignity of the position, Julius Caesar held it for the last 20 years of his life, and Augustus took it after the death of Lepidus in 12 B.C., after which it became inseparable from the office of the reigning emperor.

PONTIVY, a town of W. France, in the department of Morbihan. Pop. (1936) 7,109. Pontivy had its origin in a monastery founded in the 7th century by St. Ivo of Lindsfarne. The town, at the confluence of the Blavet with the Nantes-Brest canal, has distinct parts—the old town and that to the south known as Napoleonville and built by Napoleon I as military headquarters for Brittany.

The ancient castle (1485) of the dukes of Rohan, whose capital the town was, is a museum.

PONT-L'ABBÉ, a town of western France in the department of Finistère, 13 mi. S.W. of Quimper by rail. Pop. (1936) 5,578. The town stands on the right bank of the estuary of Pont-l'Abbé, 2 mi. from the sea. Its port carries on fishing, imports timber, coal, etc., and exports mine-props and the cereals and vegetables of the

neighbourhood. There is a church of the 14th, 15th and 16th centuries, once attached to a Carmelite convent, an old castle is occupied by the *hôtel de ville*. The local costumes, trimmed with the bright-coloured embroideries for which the town is noted, are among the most striking in Brittany; the *bigothen* or headdress of the women has given its name to the inhabitants.
